# **VENTURE CAPITALIST OPPORTUNITY RECOGNITION DIFFERENCES: EAST VERSUS WEST**

Noel J. Lindsay<sup>1</sup> and Wendy A. Lindsay  
Centre for the Development of Entrepreneurs  
University of South Australia

## **ABSTRACT**

A range of studies have focused on examining how entrepreneurs evaluate opportunities and to a lesser extent how they recognize them. This study builds upon prior entrepreneurship research into opportunity recognition (OR) behaviors and processes and extends this to venture capitalists (VCs) from two countries: Japan (the East) and Australia (the West). Much of the VC research has a western orientation and although venture capital is a global phenomenon, nation cultures may influence how VCs recognize opportunities. This research examines eastern and western VC OR similarities and differences and the OR - VC firm performance relationship. Although there were similarities between Japanese and Australian VC OR behavior and process types, there were significant weighting differences between the two groups on all but one OR behavior – opportunity causes. In addition, Japanese VCs differed from Australian VCs in terms of the relationship between OR behaviors and processes and VC firm performance.

## **INTRODUCTION**

This exploratory research investigates opportunity recognition (OR) similarities and differences and the OR-firm performance relationship of Japanese (Eastern) versus Australian (Western) venture capitalists (VCs). VC performance is dependent, in part, on recognizing opportunities (Timmons and Spinelli, 2004). Opportunities are characterized by general attributes such as the existence of a customer need, large and/or growing markets, forgiving financial returns, and having a sustainable competitive advantage (Timmons and Spinelli, 2004).

Opportunity evaluation has been the focus of substantial research. OR has been investigated less so (Hills, 1995) until only more recently (Venkataraman, 1997). As a result, how entrepreneurs recognize opportunities is still developing (Hills, Shrader, Baltrusaityte, and Izberk-Bilgin, 2002) and the literature that exists is fragmented and often appears contradictory (Lumpkin, Hills, and Shrader, 2001).

Less is known about VC OR behavior and the relationship between OR and VC firm performance. This research, therefore, is motivated by a gap that exists in the literature. In addition, much of the research undertaken is western oriented. A secondary motivation for this research, therefore, is to understand how western VC OR behaviors and processes are similar to or different from eastern VC behaviors and processes.

The research makes a contribution at two levels. First, it builds upon existing OR knowledge and extends this to VCs. In doing so, it contributes toward developing a more holistic OR theory. Second, it provides practical insights for VCs.

## MODEL DEVELOPMENT

Figure 1 provides an overview of the model that is the focus of this research.

-----  
Insert Figure 1 about here  
-----

The model builds upon the findings of Hills (1995), Hills, Lumpkin, and Singh (1997), and Hills and Shrader (1988) who focused on OR for entrepreneurs. The model identifies five OR behaviors and processes: self perceived entrepreneurial alertness to opportunities; fundamental causes of entrepreneurial opportunities; importance of venture ideas, individualism, creativity, and sources; opportunity recognition processes, deliberate search, spinoffs and immersion; and evaluation of new business opportunities. A sixth element of OR (source importance for identifying major new business ideas) reflected in the research undertaken by Hills (1995), Hills, Lumpkin, and Singh (1997), and Hills and Shrader (1988) is not incorporated in this research since VCs receive a continuous flow of potential investments from entrepreneurs wishing to raise money and each potential investment is evaluated in terms of whether it fits specified VC investment criteria.

VCs are professional investors that raise money primarily from financial institutions such as pension funds and insurance companies. They pool the monies they raise to create their own VC funds. The monies in these funds are then used for investing in growth oriented entrepreneurial firms that are assessed as having the potential to provide significant returns. By raising money from others to invest in entrepreneurial opportunities, VCs can be considered to act entrepreneurially. As such, it is expected that VCs will demonstrate OR behaviors and processes similar to those identified in entrepreneurs by Hills (1995), Hills, Lumpkin, and Singh (1997), and Hills and Shrader (1988).

Since venture capital investment in entrepreneurial ventures is a global phenomenon, it can be expected that OR will be common across cultures. What is regarded as an opportunity in one culture may be considered an opportunity in another. Similarly, the behaviors and processes that underpin how opportunities are recognized can also be expected to be similar across cultures. As such, in this research ...

- H1: The types of OR behaviors and processes adopted by Australian VCs will be similar to those adopted by Japanese VCs.
- H2: There will be no differences between the weighting levels placed on OR behaviors and processes for Australian and Japanese VCs.

Picking “winners” (successful investments that will produce super normal financial returns) is what VCs aim to achieve. Thus, by identifying superior investment opportunities from the myriad of investments presented to them, VCs aim to achieve superior VC firm performance. Thus, there will be a relationship between VC OR behaviors and processes and VC firm performance ...

- H3: There will be a relationship between *self perceived alertness* and VC firm performance for both Australian and Japanese VCs.

- H4: There will be a relationship between *opportunity causes* and VC firm performance for both Australian and Japanese VCs.
- H5: There will be a relationship between *ideas and creativity* and VC firm performance for both Australian and Japanese VCs.
- H6: There will be a relationship between *deliberate search and immersion* and VC firm performance for both Australian and Japanese VCs.
- H7: There will be a relationship between *opportunity evaluation* and VC firm performance for both Australian and Japanese VCs.

## RESEARCH METHOD

### Participants

Participants were identified using VC directories in Australia and Japan as well as by accessing industry contacts to identify VC firms not in the directory. A questionnaire was sent to these participants. The Japanese response rate was 35% (n = 83); the Australian response rate was 30% (n = 42). The Japanese survey instrument was translated into Japanese and then retranslated into English to ensure that both the English and Japanese instruments were equivalent. The questionnaire included sections on demographic information, OR, and firm performance. Table 1 provides demographic information on the participants.

-----  
Insert Table 1 about here  
-----

### Measures

An independent samples t-test and correlation analysis were undertaken to analyse the data. A validated scale developed by Hills and others was used to capture VC OR behavior and processes. Perceived alertness, causes, ideas and creativity, search, and evaluation were the underlying OR dimensions. For the Australian study, details are as follows: perceived alertness (mean = 2.029; s.d. = 0.782); causes (mean = 2.414; s.d. = 0.746); ideas and creativity (mean = 2.638; s.d. = 0.578); search (mean = 2.667; s.d. = 0.540); and evaluation (mean = 2.536; s.d. = 0.782). For the Japanese study, details are: perceived alertness (mean = 1.347; s.d. = 0.3850.); causes (mean = 2.190; s.d. = 0.895); ideas and creativity (mean = 1.841; s.d. = 0.354); search (mean = 1.780; s.d. = 0.333); and evaluation (mean = 1.733; s.d. = 0.391).

VC firm performance was measured using the Internal Rate of Return which is the standard VC industry performance measure (Mason & Harrison, 2002). Respondents were asked to rate the IRR of the entire portfolio of their investments in absolute terms ("1 = over 20%" to "5 = less than 5%"). This was referred to as the IRR performance scale. For the Australian study, mean = 1.952, s.d. = 0.936; for the Japanese study, mean = 3.084, s.d. = 1.232.

## RESULTS

Tables 2.1 and 2.2 provide the Australian and Japanese Correlation Coefficients and Descriptive Statistics.

---

Insert Tables 2.1 and 2.2 about here

---

H1 hypothesized that OR behaviors and processes adopted by Japanese VCs will be similar to those adopted by Australian VCs. This hypothesis was confirmed. Both Australian and Japanese demonstrated use of the five OR behaviors and processes.

H2 hypothesized that there will be no differences between the weighting levels placed on OR behaviors and processes for Australian and Japanese VCs. This hypothesis was disconfirmed. An independent samples t-test was conducted to compare the five OR behaviors and processes of each group. Significant OR differences on four of the five behaviors and processes were identified: perceived alertness ( $t(123) = 6.540, p = 0.000$ ); causes ( $t(123) = 1.394, p = 0.166$ ); ideas and creativity ( $t(123) = 9.530, p = 0.000$ ); search ( $t(123) = 11.325, p = 0.000$ ); and evaluation ( $t(123) = 7.664, p = 0.000$ ). There was no significant difference between the two groups with opportunity causes.

H3 hypothesized that there will be a relationship between *self perceived alertness* and VC firm performance for both Australian and Japanese VCs. This hypothesis was only partially confirmed. A relationship existed for Australian VCs but not for Japanese VCs.

H4 hypothesized that there will be a relationship between *opportunity causes* and VC firm performance for both Australian and Japanese VCs. This hypothesis was only partially confirmed. A relationship existed for Japanese VCs but not for Australian VCs.

H5 hypothesized that there will be a relationship between *ideas and creativity* and VC firm performance for both Australian and Japanese VCs. This hypothesis was disconfirmed.

H6 hypothesized that there will be a relationship between *deliberate search and immersion* and VC firm performance for both Australian and Japanese VCs. This hypothesis was disconfirmed.

H7 hypothesized that there will be a relationship between *opportunity evaluation* and VC firm performance for both Australian and Japanese VCs. This hypothesis was only partially confirmed. A relationship existed for Australian VCs but not for Japanese VCs.

## DISCUSSION

The results have implications for VC research specifically and for OR research generally. First, the results highlight the independence of the OR behaviors and processes. Though related, these can vary independently of each other. Each can independently influence performance.

Second, culture may provide a possible explanation for VC firm differences. National culture is programmed into us from the day we are born. Culture is the collective programming of the mind that distinguishes the members of one category of people from another (Hofstede, 1980). Culture can be measured in terms of (Hofstede, 1980) power distance (level of preference for equality or inequality within groups), uncertainty avoidance (preference for risk versus structure), individualism (degree of individual or group orientation), masculinity (relative degrees of relationship versus task orientation), and long term versus short term orientation (thrift and perseverance versus respect for tradition and fulfilling social obligations) (Hofstede, 1991; The Chinese Culture Connection, 1987).

Although culture does not equate with nations (nations may be multi-cultural), culture provides a partial explanation of nation differences. Hofstede (1980), for example, identified cultural profiles for a range of nations including Australia and Japan. Compared to Australia, Japan has a higher power distance, a much lower tolerance for uncertainty and risk, much less of an emphasis on the individual and more on the group, a greater masculine task orientation, and a much longer time orientation. Since significant cultural differences exist between the two countries, and culture affects beliefs, attitudes, and behavior, it is not unexpected that there will be significant OR differences between Australian and Japanese VCs. All VCs need to recognize and invest in profitable opportunities; culture, however, can be expected to influence *how* VCs recognize opportunities. As such, VC OR models and decision aids need to consider culture as an important contextual variable.

Third, it is apparent that Japanese and Australian VCs emphasize different OR behaviors and processes. OR is underpinned by a number of behaviors and processes and VC firm performance may be enhanced through using a more holistic OR approach. Thus, from a practitioner perspective, it may be beneficial for VCs to spend time in other countries (immersed in other cultures) so as to develop a more holistic appreciation of foreign approaches to OR dimensional weighting with a view to supplementing “local” with “foreign” OR dimensional emphases.

### **Managerial Implications**

VCs are professional investors; however, they do not necessarily “get it right” every time and get a 100% success rate. Since OR appears to be related to VC performance, it would appear that training VCs (particularly novice VCs) to better understand OR behaviors and processes and opportunity characteristics would be beneficial to them. In addition, by enhancing their OR behaviors and processes, they may be better positioned to mentor their investments which, in turn, may result in improved performance of those investments.

### **Research Limitations**

There are a number of limitations associated with this research that may influence the generalizability of results. First, the research did not include VCs from countries other than Australia and Japan. As such, the generalizability of the results to other eastern and western countries should be done so with caution. Second, the Australian VC industry is relatively young when compared to US and European VC industries. As such, generalizability of the Australian results to more mature country VC industries also should be done with caution. Third, only successful venture capitalists were examined (those that were still operating). There is a need in future research to examine the OR-performance relationship in less successful VC firms. Fourth, the sample size of Australian VCs used in this research appears small. However, the Australian VC population is relatively small with there being probably no more than 150 VC Australian firms (Bivell, 2005).

## **SUMMARY**

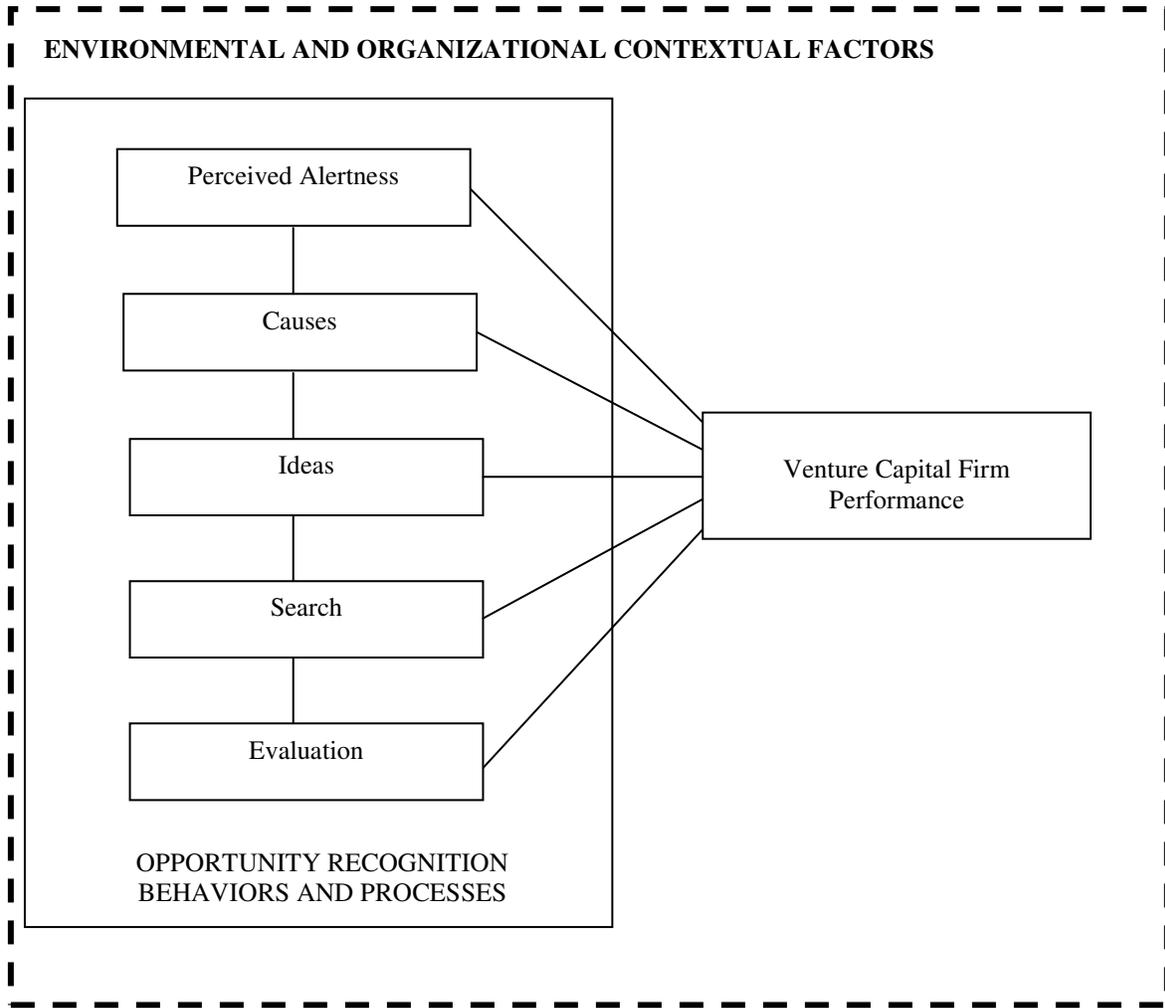

This research examined the OR behaviors and processes of Japanese and Australian VCs and the OR-VC firm performance relationship. Although both Australian and Japanese VCs used similar OR behaviors and processes, each group applied different OR behavior and process weightings resulting in different OR behavior and process firm performance relationships.

# SME FINANCIAL STRUCTURE AND THE IMPLICATIONS FOR REGIONAL ECONOMIC POLICY DEVELOPMENT IN NEW ZEALAND

Stuart Locke  
University of Waikato Management School  
New Zealand

## ABSTRACT

This paper reports on an investigation into the potential to use the financial ratios of New Zealand small businesses to discriminate their location as an aid for in the accurate targeting of regional economic development programmes. To the extent that there are clearly identifiable differences in performance and financial structure for urban and non-urban firms this could be significant for small business policy development and the efficient implementation of strategies.

An expanded awareness of the role of small business in employment generation and sustainable economic growth has resulted in more government attention being directed toward the sector. The non-interventionist approaches of the 1980s and 1990s have given way to more proactive government policies to achieve economic and social growth. As government becomes more active in working for and with small business it is important that scarce resources should not be wasted but directed toward gaining the best pay-off.

The paper discusses the data sources, the statistical testing, the results, the interpretation of the findings and finally a range of policy implications. While the statistical analysis is rigorous and robust the focus is upon the results and implications and not upon the statistical analysis per se.

## INTRODUCTION

Government policy, in New Zealand, has increasingly incorporated strategies supporting economic growth, including programmes which encompass the small medium enterprise (SME) sector. The initiatives are directed toward reducing compliance cost, regional development and maximising expected value added through export encouragement. The aim of this study is to analyse subsets of SMEs distinguished by their regional base to determine whether there are detectable structural differences which may be of importance in maximising the outcomes of government programmes directed toward improved economic growth.

One target mooted at the last national election, in 2002, was to move New Zealand into the top half of the OECD rankings for income per capita. At the opening of the parliamentary session The Governor General, delivering the Speech from the Throne, observed that the new government "sees its most important task as building conditions for increasing New Zealand's long term sustainable rate of economic growth".

That broad theme enunciated in 2002 continues to be an important target. The head of Treasury, speaking at a conference in mid 2004 noted that:

*If New Zealand is to catch-up to OECD average level of per capita GDP then New Zealand will need to grow faster than average OECD growth, which means growing faster than some countries.*

*Just how challenging that will be will depend on how fast other countries above and below us perform. To catch up with the OECD median in ten years for example, New Zealand per-capita GDP has to grow approximately 2% more on average per annum than the OECD median for the next 10 years. Over a 20 year horizon the required rate is about 1% more than the OECD.*  
(Whitehead, 2004)

The SME sector is increasingly recognised as an important component of the economy. Government continues implementing a range of policy initiatives directed toward providing stable macroeconomic conditions, enhancing labour productivity, regional development and removing constraints to trade, etc. Of particular significance, to this study, are a number of policies directed toward improving productivity in the SME sector and targeting key areas with a growth innovation framework (GIF).<sup>b</sup>

The initial proposals regarding the growth innovation framework (GIF) were promulgated by Prime Minister Helen Clark (2002) as a key plank in the Government's policy framework for economic transformation. The framework, *Growing an Innovative New Zealand*, has three key elements:

- Strengthening the economic foundations
- Investment in innovation, talent and global connectedness
- Sectoral policies focussing on the bio-technology, ICT and creative sectors.

Subsequently the GIF has been extended to include regional development as a key component of current economic development efforts. Significant drivers of growth arise at regional and local levels through the opportunities and incentives provided by region-specific attributes. The government has adopted a partnership approach to regional development. This includes the Regional Partnerships Programme under which local government, Iwi<sup>1</sup> and economic development professionals work together on economic development strategies to make the most of regional strengths and local resources. Central government provides support to build the capacity of each region in establishing the foundations for sustainable economic growth (MED, 2004b).

### **SME SECTOR IN NEW ZEALAND**

The 2004 report of Small Business Advisory Group, an independent committee established by government to make recommendations relating to SMEs, made 19 recommendations. There were no links with the regional economic development policy of government.

MED (2004b, p12) addresses the size of output attributable to SMEs. Using value-added<sup>2</sup> as a measure of the contribution to total output in the economy that SMEs

---

<sup>1</sup> Iwi are tribal groupings of Maori people, the indigenous people of Aotearoa/New Zealand.

<sup>2</sup> Value-added is calculated as gross output minus intermediate consumption and is provided with the following caveats:

- Value-added is calculated as gross output minus intermediate consumption. This should only be seen as a proxy. While source data used for this feed into the system for National accounts from which official GDP is calculated, these data have not been through this process and therefore only provide an indicator.
- The numbers have been deflated by a generic deflator which is not output specific and are not related to GDP published by Statistics New Zealand.
- These data are not standard output and as such are not available in any other cross-tabulations.
- Figures expressed in terms of 1997 dollars.

accounted for 38 percent of total output in 2002, with small enterprises making up over half of that portion.

Figure1 about here

The regional make-up of SMEs, as shown in Figure 1 sourced from MED 2004a, is heavily biased toward Auckland, reflecting the concentration of population in that region. Other regions while exhibiting numbers far less than Auckland, nevertheless, have a significant number of firms which may present potential for stimulating employment and product growth throughout most regions.

From Figure 2 it is apparent that the proportion of total employed varies from 36.7% in Wellington, the nation's capital with a strong public sector base, to 57.3% in Tasman, a tourist oriented horticultural and agricultural region.

Figure 2 about here

The linkage between regional policy and SME performance requires further research. Karlsson and Dahlberg (2003) discuss three factors they consider to be of particular importance regarding how the regional context relates to SME performance. First, social capital transmission is typically bounded by region differences. This view is supported by the Westlund and Bolton (2003) who describe how the social capital platform enhances SME surplus generation, noting that social capital variability is consistent with spatial differences in SME performance. Second, knowledge is suggested as being rooted in regions. The accession and participation in knowledge requires geographical proximity. SME clusters, industry training organisations and tertiary education provision tend to have a regional base. Third, the regional dimensions of geographical transaction costs, internal and external economies of scale, and self reinforcing growth are of significance in determining sustainable SME performance.

Until relatively recently there were few empirical data, for New Zealand, providing a comprehensive oversight of regional economic performance.

### **REGIONAL PERFORMANCE**

The lack of regional economic accounts poses a range of difficulties for the assessment of regional economic performance. A recent official study found:

- Economic activity and growth are unequally distributed amongst New Zealand regions.
  - The inequality between New Zealand regions is not substantial, with some notable exceptions.
  - Canterbury and Wellington are regional star performers, while Northland has under-performed.
  - A significant portion of inter-regional economic variation appears to be explained by labour market and demographic variation (although this partly relates to the method of regional GDP estimation employed).
-

- Gaps in regional data make explaining inter-regional economic variation difficult. (MED, 2004a).

The report considers a number of industrial classification groupings such as government, agriculture, etc. and compares the share of nominal national GDP with regional GDP. The proportion of national GDP is plotted on the Y axis and the proportion of regional GDP is plotted on the X axis. Figure 3, which is Figure 22 in the MED report, presents the position for the Waikato region. It is apparent that the Waikato is strongly represented by the Agricultural sector, plotting well to the right of the diagonal line. Anything plotting on the diagonal indicates the region is equal to the national average. The Waikato is under represented by business services.

Figure 3 about here

New Zealand Trade and Enterprise is the government agency charged with delivering regional development programmes. The primary thrust of their services includes:

1. Business development:
  - businesses starting up and at an early stage of development.
  - businesses seeking to grow and internationalise: including new exporters, high growth businesses and other exporters.
  - investment services, providing New Zealand business information as well as extensive networks for investors seeking existing and start-up New Zealand-based ventures with excellent future potential.
2. Business Partnerships:
  - Supporting companies working together in export networks and regional and national clusters to achieve higher growth.
3. Regional Development:
  - Working with and funding regions to grow by encouraging them to focus on their regional advantages.
4. Industrial Capability Network:
  - Providing access to government markets through a low cost, one port of call service.
  -

### **SME FINANCIAL STRUCTURE**

Financial ratios are widely used for investment analysis and other purposes relating to large and small businesses alike. It is generally accepted that certain ratios are of importance in terms of performance while others are more closely associated with liquidity and solvency. These matters are widely discussed in accounting texts and more specialist books directed toward financial statement analysis, eg White et al (2003). It is further recognised that financial ratios may vary between industries and between countries. Walsh (2004) appendix 3 provides examples of the distribution of many key financial ratios across several industry groupings and countries. In Figure 4 below an illustrative extract is presented.

Figure 4 about here

As is apparent there is variability in the ratio both between sectors and between countries. Similar findings are reported by Walsh across a broad range of ratios.

Financial ratios are widely used in lending decisions by financial institutions, credit rating, performance assessment and forecasting future performance. The movement

to use more than one financial ratio in the decision calculus, ie multivariate analysis rather than univariate analysis increasingly leads to more sophisticated statistical techniques. Altam (1968) used discriminant analysis to develop and test a bankruptcy prediction model. The study involves dividing a sample of companies into two groups, viz those that failed and non-failed. Each financial ratio is arranged as a descending array, ie from highest to lowest value. The discriminant analysis technique determines the optimal cut-off point for discriminating between the failed and non-failed groups.

Subsequent studies have tended to focus on many of the same ratios. Gentry et al (1984) reported on 14 multivariate studies noting that liquidity and solvency ratios were the most commonly used followed by profitability and activity ratios. Recent studies have considered the performance of companies and looked at the ratings awarded by rating services such as Standard and Poor.

Potentially, similar differences might be detected between SMEs based in large city, provincial city, town and rural environments. If the financial structure of small business does differ between urban, provincial and rural areas, then this may provide a clearer guidance as to where to target policies in order to affect growth increases. A sufficiently robust set of financial data is a precursor to such an empirical investigation.

#### **DATA**

Financial statements for the SME sector are not readily available in New Zealand as there is no requirement for smaller businesses to file annual reports as is the case for larger companies. Although taxation returns are compulsory these are not available in the public domain. For the purposes of this study data for a sample of small businesses are extracted from an annual survey of SMEs undertaken by the Management Research Centre of the University of Waikato for the Institute of Chartered Accountants. Changes to the annual financial statement survey, which has been conducted for 27 years, introduced in 2003 allow for the tracking of individual businesses through a confidential unique numbering system. Data on 35 financial ratios, as shown in Table 1, are available for over 3000 businesses and it is possible to match 1700 firms as present in the 2003 and 2004 surveys. The actual collection instruments are completed by chartered accountants, with the permission of their client businesses, and aggregate results are made available to members of the Institute of Chartered Accountants and extensively used for benchmarking purposes. Prior research, using the MRC data has established the robustness of the data (Locke, (2002), Locke and Scrimgeour (2003)).

Table 1 about here

#### **ANALYSIS**

The aim of the analysis is to establish whether it is possible to determine accurately whether businesses operate in major urban cities, provincial towns or rural centres based upon the value of some of their financial ratios. The analysis proceeds through a series of steps.

First, are the financial ratios for firms across regions the same? In order for the ratios to have a role in discriminating between regions there needs to be a difference in ratio values between regions. Various statistical tests are available to consider this question.

In particular they are testing a hypothesis that there is no difference in the ratio values between regions. An analysis of variance (ANOVA) test is undertaken as the simplest way to proceed. Several further statistical procedures are undertaken to ensure the robustness of the analysis. As the power of test statistics are affected by such issues as the variance of the ratios refinements are followed to limit the potential error of determining the ratios are the same between regions when they are different and vice versa<sup>3</sup>. Post hoc tests<sup>4</sup> are undertaken to minimise the likelihood of finding a specific ratio differs between regions when it does not. In addition to the ANOVA procedure pair-wise T-tests were taken for the different regional classifications for all ratios to test the hypothesis that the ratios are the same. After these processes it was found that some ratios do differ between regions.

Table 2 about here

The initial analysis indicates that there are statistically significant differences between regions for some financial ratios. The stability of the differences between years was tested by comparing 2002 and 2003. For the majority of ratios where a difference is exhibited in one year it continues to be the case for the next year.

The second question to investigate is whether knowing the ratio values will allow for accurate prediction of where the business is located. Discriminant analysis is applicable for building “a predictive model of group membership based on observed characteristics of each case. The procedure generates a discriminant function (or, for more than two groups, a set of discriminant functions) based on linear combinations of the predictor variables that provide the best discrimination between the groups.” (Field, 2003, p 342).

The results of the discriminant analysis indicate that three variables were capable of discriminating between the three regional settings urban, provincial and rural. The three financial variables are:

- Cost of Goods Sold
- Total Overheads
- Working owners (fulltime equivalents)

### **POLICY IMPLICATIONS**

The findings suggest there are financial differences in the ratios of SMEs in different geographical regions. To the extent that government policy is directed toward strengthening the SME sector further investigation of the ratio differences could prove fruitful. The times-interest-coverage ratio is both lower and has a lower variance for SMEs in non-metropolitan centres. An investigation of why may determine that given the majority of financial institutions operate nationally there may be a lower degree of business specialisation available in non-metropolitan settings and a higher degree of conservatism operates. Potentially such an inhibition in using increased gearing may lower growth opportunities. Structural differences in the ratios may assist in pointing to issues requiring regional policy refining.

---

<sup>3</sup> Levene test

<sup>4</sup> The tests used are Tamhane, Dunnett T3, Games-Howell and Dunnett C.

Where government policy, as noted in the discussion above, is more directed toward SMEs with growth, and especially exports oriented growth, the financial structure in terms of growth readiness is important. However, the findings to date do not indicate there is a clear statistical selection scanning process likely to emerge.

The government initiatives, in respect of lowering compliance costs, do bear directly on the cost of operations of SMEs. The statistically significantly higher overheads faced by business in metropolitan centres, however, are more closely attributed to rent differences.

Non-urban SMEs have a higher proportion of owner participation in the staffing. This is not necessarily a function of size and growth, however, further work is needed. However, the data indicates that firms in the upper quartile of growth (ratio 26) do have a higher number of employees per owner. A tentative hypothesis, nevertheless, is that employment readiness in non-metropolitan areas may be lower. This could have implications for rural education, apprenticeship schemes and tertiary/community education.

### **FURTHER RESEARCH**

The opportunity to investigate the structural differences between firms of differing lives and differing growth rates will be pursued using the current database. Hopefully it will soon be further augmented with the calendar 2004 data becoming available.

### **CONCLUSION**

The analysis has indicated that there are discernible and consistent differences in the financial structure of SMEs operating in metropolitan, provincial and rural areas of New Zealand. Government is becoming more active in policy formulation and implementation to assist the small business sector. The general thrust of policies is twofold. First, reduce compliance cost and second to assist businesses or clusters of businesses that look likely to exhibit significant growth, especially export oriented growth.

The regional development policy does not appear to be sufficiently clear, at this juncture, to establish a clear nexus between SME financial structures and government policy. To the extent that policy is looking for stability, employment growth and non-inflationary expansion, then the encouragement of more employees and less owner concentrated participation is likely to be of significance in the non-urban centres.

Ethical Attitudes in Small Businesses and Large Corporations: Theory and  
Empirical Findings from a Tracking Study Spanning Three Decades

Justin G. Longenecker, Carlos W. Moore, J. William Petty, Leslie E. Palich, & Joseph A. McKinney  
Hankamer School of Business, Baylor University  
Waco, Texas 76798-8006  
(254) 710-6176

**ABSTRACT**

The current paper offers a theoretical framework of ethical behavior and a comparative analysis of ethical perceptions of managers of large, mostly publicly-traded corporations (those with 500 or more employees) and the owners and managers of smaller companies (those with fewer than 100 employees) across 17 years. The primary research provides basic data on the changing standards of ethics and as perceived by leaders of large and small businesses, where the cultures frequently fall into sharp contrast.

Our findings reveal the extent to which the message of business integrity is gaining or losing ground within large and small companies. It does this by means of respondents' judgments of acceptable responses to 16 scenarios profiling common business situations with questionable ethical dimensions. Respondents were surveyed by mail and represented each state in the United States. They were also asked questions about themselves and their businesses, as well as the ethical climate within their companies.

Based on responses from over 5,000 managers and employees (from firms of all sizes) to our scenarios at three points in time (1985, 1993, 2001), we found evidence of trends in expected ethical behavior. We test two research questions by creating an Ethics Index.

These questions were: *RQ1: For firms of all sizes, have business ethics improved or*

*declined between the years 1985 and 2001? RQ2: Comparing responses of large and small firm executives across the 1985-2001 time frame, is there a discernable difference in their ethical standards?* Our results suggest business leaders are making somewhat more ethical decisions in recent years.

## **INTRODUCTION**

In the wake of recent, well-publicized ethical failures, public attention and the concern of leaders in business and government have focused on the moral climate of corporate America. This awareness and concern is raising expectations for ethical behavior, including those codified into law (e.g., Sarbanes Oxley legislation), and creating societal pressures for reform. Business leaders need to understand the nature and scope of the problem.

The media's focus on business ethics has related primarily to large, publicly-traded corporations. However, the issue of ethical behavior and indiscretion in business is a concern for all companies, regardless of size. Indeed, the rising importance of entrepreneurial firms to economic growth and development around the world has prompted some to criticize the limited attention small business receives in the ethics literature (e.g., Carr, 2003; Sorrell, 1998; Spence & Rutherford, 2003). It is our intent to shed light on ethical realities in firms of all sizes, with a special emphasis on small companies.

After unfolding a framework reflecting common streams of business ethics theory, especially as they apply to firms of different sizes, we establish a baseline for ethical perceptions of American business professionals over a 17-year period. Our findings reveal the extent to which the issue of

business integrity has varied in importance within large and small companies. The results are based on respondents' judgements of acceptable responses to 16 scenarios profiling common business situations with questionable ethical dimensions. Specifically, we track responses to an extensive questionnaire mailed to firms of various sizes at three points in time over an extended period. The study then offers a comparative analysis of ethical perceptions of managers of large, mostly publicly-traded corporations (those with 1,000 or more employees) and the owners and managers of smaller companies (those with fewer than 100 employees) across the same time frame. The research provides basic data on the changing standards of ethics as perceived by leaders of large and small businesses, where the cultures and circumstances may be in sharp contrast. It also provides information concerning pressures to act in ways that may be harmful to the public good.

The current study is unique in several ways. First, the findings are based the largest sample size used in any study on business ethics, with over 5,000 respondents included in the analysis. Second, the survey was administered at three points in time (1985, 1993, and 2001), collecting data that spans three decades. This allows us to look for general trends as well as for the impact of events and scandals in specific time periods. Third, the questionnaire has changed little over this time frame and has been handled by the same research team, thus ensuring consistency and comparability of data. Finally, the data are arranged to allow specific tests of differences between large and small firms, which is the focus of the study. These features, among others, set the current study apart from other tests of ethical standards conducted to date.

## ETHICAL PERCEPTIONS IN CORPORATE AMERICA

Each decade presents its own high-profile scandals. The Watergate break-in and subsequent hearings in the 1970s, followed by insider trading and a rash of corporate raiding in the 1980s; the Lewinski affair and impeachment proceedings in the 1990s; and the meltdown of corporate giants such as Enron, Arthur Anderson, WorldCom, Tyco, and Adelphia (to name only a few) just after the start of the current century. Bruce Nussbaum of *Business Week* described the latest round of corporate debacles as being "...so vast and so penetrating that they profoundly shock our most deeply held beliefs about the honesty and integrity of our corporate culture" (Nussbaum, 2002: 31-32).

The foregoing events have spawned common perceptions of ethical behavior in the U.S. that are strikingly negative. A number of empirical studies support these perceptions. For instance, Vitell, Dickerson, and Festervand (2000) asked 153 business professionals how ethical standards compare with those of the past. They found that 50.3% of the respondents said ethics were currently lower than they were 10 years earlier, compared to only 14.3% who said they were higher. Even more profound, 65.2% said ethical behavior had declined over the past 20 years, versus a mere 12.5% who thought ethical standards had risen. These findings provide evidence of perceived degradation in ethical standards over time.

Baumhart (1961) found that most business executives believe they are more ethical than their peers. In a subsequent study, Brenner and Molander (1977) replicated Baumhart's study and concluded that ethical standards had declined during the time that had passed (though they surmised that the decrease may have been an artifact of higher legal standards and increased

government enforcement). Over the 1980s, Zinkhan, Bisesi, and Saxton (1989) studied the responses of MBA students to marketing dilemmas and found erosion in ethical attitudes and responses. For the most part, participants were more willing to use deceptive advertising, be dishonest in marketing research, and employ questionable intelligence gathering methods.

The findings above are certainly consistent with the prevailing perceptions of ethical decline over time. However, other research initiatives seem to lean in the opposite direction. In 1987, Vitell and Festervand (1987) replicated the 1977 study by Bremer and Molander and found that ethical standards seemed to be higher than in the past, exactly the reverse of the previous extension. And they are not alone. The pattern repeats in other replications of similar studies. Though the results have not been completely uniform across all issues and situations, empirical evidence of improvement in ethical standards exists. Clark (1966) used responses to 11 vignettes to assess the “personal ethics” (i.e., commitment to honesty and integrity, even if it reduced personal gain) of 103 business executives. Using the same vignettes to permit valid comparisons, Harich and Curren (1995) surveyed 76 executives after a 30-year lag and found statistically significant improvements in ethical commitment.

While its studies mentioned above, found both positive and negative trends, other studies have not found any significant intertemporal changes. For example, Arlow & Ulrich, (1988), and Stevens, (1984) failed to find any statistically significant differences in responses after substantial time lags.

Taken together, the studies described above seem to represent a mixed bag of findings, at best. Given that no definite pattern or cogent theoretical position has emerged, we re-examine the issue of changing ethical standards by drawing on a sample of unequal size in earlier studies.

Therefore, we set up our test around the following research question:

*RQ1: For firms of all sizes, have business ethics improved or declined between the years 1985 and 2001?*

### **A FRAMEWORK FOR ETHICAL RESPONSES IN LARGE AND SMALL FIRMS**

Factors that influence ethical perceptions and behavior are multidimensional; that is, they are rooted in differences between individuals, variations in their organizational settings, and the interplay between the two. This orientation finds a firm foundation in recent psychological theory, as expressed by Kendrick, Maner, Butner, Li, Becker, & Schaller (2002: 347).

Rather than focusing exclusively on factors inside the person or in the environment, psychology is an increasingly interactionist discipline. Psychologists now envision internal predispositions interacting with environmental inputs to affect ongoing thoughts and feelings in a continual and dynamic manner.

Succinctly stated, ethical behavior does not emerge from the value sets of individuals in isolation from external influences, which is the upshot of established models in the ethics literature.

Trevino's (1986) "person-situation interactionist" model is one form of an ethical decision-making model that incorporates this perspective. She avers that these choices arise from personal variables (e.g., cognitive moral development, ego strength, locus of control), situational factors (e.g., the organization's normative structure, reward systems, and accountability emphases), and reflexivity between the two. Indeed, this general formulation is found in other frameworks in the ethics literature (Weaver & Agle, 2002). Though some suggest organizational influences overpower personal values in ethical decision making (e.g., Jackall, 1988), other

researchers argue for the critical role of individual factors and their interaction with situational circumstances. We offer below some of the highlights of this research to inform our discussion of the differences between entrepreneurs or small business managers and their large firm counterparts. The major factors described below are presented in Exhibit 1 and are discussed in the following two sectors.

-----  
Insert Exhibit 1 about here  
-----

### **Personal Factors**

As reflected in Exhibit 1, there are a number of personal factors that may have an impact on an entrepreneur's ethical values and behavior. Let's consider each in turn.

**The Entrepreneurial Act.** Entrepreneurs are clearly unique individuals. And at the heart of the entrepreneurial act is the identification of opportunities that have not been tapped, often because of obstacles that stand in the way of their exploitation. However, overcoming these impediments can require the entrepreneur to walk a fine line between creative practice and maintaining the boundaries established by social convention—or even staying within the law. Nonetheless, entrepreneurs are often celebrated because of their creative solutions and “rule bending” efforts, many of which are effective precisely because the entrepreneur is willing to enter regions of opportunity that can be accessed only by passing through behavioral gates that most people would hesitate to open (Morris, Schindehutte, Walton, & Allen, 2002).

Bhide and Stevenson (1990) mention the deceptive practices employed by Philippe Kahn, founder of Borland International, a startup launched to develop and market programming

languages and software applications for personal computers. At a critical juncture in its history, the company would not have survived if it had not placed a full-page ad in the November 1993 issue of *BYTE* magazine to reach a critical market and drive demand for its product. However, there was no way the company could afford the ad, and the venture was so high-risk that the magazine would not have extended credit terms—that is, if they had known the true condition of the business. Kahn describes, with apparent relish, how he solved the problem.

...before the ad salesman came in—we existed in two small rooms, but I had hired extra people so we would look like a busy, venture-backed company—we prepared a chart with what we pretended was our media plan for the computer magazines. On the chart we had *BYTE* crossed out. When the salesman arrived, we made sure the phones were ringing and the extras were scurrying around. Here was this chart he thought he wasn't supposed to see, so I pushed it out of the way. He said, "Hold on, can we get you in *BYTE*?" I said, "We don't really want to be in your book, it's not the right audience for us." You've got to try," he pleaded. I said, "Frankly, our media plan is done, and we can't afford it." So he offered good terms, if only we'd let him run it just once. We expected we'd sell maybe \$20,000 worth of software and at least pay for the ad. We sold \$150,000 worth (Bhide & Stevenson, 1990: 122-123).

This story illustrates how the entrepreneurial act, at its core, can sometimes spawn its own ethical dilemmas, and long-time or serial entrepreneurs may find it difficult to separate the entrepreneurial from that which is arguably unethical. These issues are less likely to arise in large corporations.

**Cognitive Moral Development.** Lawrence Kohlberg's (1969) theory of cognitive moral development (CMD) is often mentioned in discussions of ethical decision making. This theory posits that each person, as a result of life experiences, develops cognitive skills that guide decision making related to moral issues. It follows that individuals make different moral judgements about an issue depending on their level of CMD. Those who are at the preconventional level (stages one and two) make decisions based on concrete personal

consequences (i.e., anticipated rewards and punishments). The conventional level (stages three and four) emphasizes conformity mostly to societal expectations. The principled level (stages five and six) is the highest, and at this point the focus shifts to broad ethical principles. In accord with Kohlberg's theory, Trevino and Youngblood (1990) used an in-basket experiment to show that higher CMD participants made more ethical decisions, and research by Stratton, Flynn, and Johnson (1981) found that students who rejected an expense-padding practice used higher levels of CMD to support their decisions.

Expanding the application of this framework, Teal and Carroll (1999) assessed the CMD level of a sample of entrepreneurs and compared their scores to a baseline established by previous research (Rest, 1986). They found that 30.77% of the owner/managers in their sample had *P*-scores (a common measure of CMD) above 50. Because Rest reports that *P*-scores above 50 are relatively rare, Teal and Carroll concluded from the performance of their sample that entrepreneurs may operate at a higher level of CMD than others and thus are likely to maintain higher ethical standards (Solymossy & Masters, 2002).

**Locus of Control.** Research also has shown that entrepreneurs tend to have a strong internal locus of control (Shaver & Scott, 1991); that is, they believe their destiny or experienced outcomes are a function of the effort they expend, rather than the result of life factors that are beyond their power (an external locus of control). This may have ramifications for ethical behavior. According to interactionist logic, the influence of environment can be substantial; however, because entrepreneurs tend to have a stronger internal locus of control, it follows that they are more likely to make decisions based on their personal ethical standards, rather than

rationalizing their behavior by attributing it to external factors (Hegarty & Sims, 1978).

However, research on the issue is mixed. Zahra (1989) and McCuddy and Peery (1996) found that external locus decision makers are less sensitive to problems with unethical behavior, but Hegarty and Sims (1978, 1979) did not find support for such a linkage with ethical standards. Implications for ethics in small versus large firms thus appear to be equivocal.

**Need for Achievement.** Entrepreneurs often have a high need for achievement (Begley & Boyd, 1987; McClelland, 1961; Miller, 1983; Solymossy, 1998), which may have ramifications for ethical decision making. Need for achievement may negatively impact ethics by the influence it has on business priorities. If entrepreneurs are focused on achievement, then they may be inclined to sacrifice other concerns, including their personal ethics. Offsetting this line of reasoning, research has indicated a positive link between need for achievement and moral development (e.g., Glover, Bumpus, Logan, & Ciesla, 1997; McClelland, 1961), where the latter is associated with higher ethical standards. Thus, the connection between achievement need and ethics is unclear.

**Machiavellianism.** Another personal factor hypothesized to play a role in ethical perceptions and decision making is machiavellianism, which relates to a willingness to influence others for the sake of personal achievement. Entrepreneurship is often associated with machiavellian tendencies that can lead to the bald exploitation of others and ethical compromise. King and Roberts (1992) caution that entrepreneurs can be master manipulators who are quick to take advantage of others unless they are restrained by adequate accountability. The profile suggests that entrepreneurs are less likely to be guided by high ethical standards than others who are less

imbued with machiavellianistic inclinations (Morris et al., 2002). This is consistent with Longenecker, McKinney, and Moore's (1988) speculation that entrepreneurs are more inclined toward egoism (i.e., viewing an act as moral if it promotes the individual's best long-term interests) and are thus less ethical in their behavior.

**Social Costs.** Some researchers focus on the social dimension of small business as a factor that differentiates the ethical practices of entrepreneurs from those of their large firm counterparts. They emphasize that small companies have unique needs and circumstances, and studies show that they are very sensitive to some ethical issues and much less so to others (Longenecker et al., 1989; Vitell et al., 2000). Furthermore, small firms are likely to be owner-managed, which sets up very different dynamics from those found in large corporations, where ownership and management are separated for the sake of gains from specialization. As a result, the ethical values and inclinations of the small business owner have a far more direct affect on the practices of the business as a whole (Spence & Ruthrefoord, 2003).

It is also true that the business relationships and personal networks of small company owner-managers often overlap substantially, which increases the social cost of unethical decisions. Brass, Butterfield, and Skaggs (1998) refer to this as "multiplexity" (i.e., the degree to which individuals share more than one relationship, such as those who have business dealings but also are close friends, neighbors, or members of the same church) and describe how this tends to constrain business behavior. If multiplexity is present, then maintaining high ethical standards in the marketplace can reduce the probability of strained relationships in other contexts, which discourages unscrupulous behavior. In addition, an owner/manager's sense of personal identity

tends to be tightly coupled with the enterprise, so reputation is highly prized and carefully guarded. In fact, Mayo (1991) reports that entrepreneurs are often more concerned about the impact of their business conduct on their reputations than on the performance of their ventures. And given the crucial role of trust in building relationships with suppliers, customers, creditors, and others, reputation can be an essential platform for enterprise growth (Aldrich & Fiol, 1994). Based on these arguments, it follows that the social dimensions of entrepreneurship play an important role in promoting ethical behavior in small companies.

### **SITUATIONAL FACTORS**

As indicated by Trevino's (1986) person-situation interactionist model, there are also situational factors, as well as personal factors (some of which are outlined above), that impact the ethics of organizational decision makers. Some of these relate to the environment of entrepreneurial firms, broadly defined, while others are institutional in orientation or relate to the agency relationships that are established in organizations. We will discuss each of these in turn.

**Environmental Factors.** Morris et al. (2002) outline a number of "environmental forces" to which entrepreneurial firms are uniquely subject, including cash reserve limitations, dependence on a narrow range of product or service offerings, and limited market presence, which leaves the firm vulnerable to disabling fluctuations in demand, competitive attacks, and supplier or distributor neglect. Added to this list of contextual factors is the liability of smallness and the liability of newness, which recognize, respectively, that entrepreneurial firms often lack scale advantages and are prone to make mistakes as a result of inexperience (Aldrich & Auster, 1986;

Morris & Zahra, 2000). Morris et al. (2002: 333) explain that these factors are relevant to ethics in entrepreneurial firms because

... [they] often result in conditions that encourage or justify ethical compromises. These conditions include time pressures, cash shortfalls, the fact that making compromises can mean the difference between venture survival and failure, the power position of the entrepreneur, the lack of reference points for acceptable and unacceptable behaviors, and the reduced public visibility of the firm. Further, and contrary to arguments made by both ethicists and economists, there may be no payoff for ethical behavior.

Indeed, the circumstances faced by entrepreneurs are often so hostile and challenging that the incentive to compromise ethically may seem impossible to overcome, especially when slack resources are limited and the margin for error is squeezed. And these pressures are only intensified by the fast-paced environment of the Internet age.

**Institutional Factors.** There is no question that large firms have had more time to develop the institutional infrastructure necessary to guide decision making. In fact, this can work against the organization when it engenders inertia that moves the corporation along a stable vector that precludes adjustment to changing trends and emerging conditions. However, when it comes to ethical standards and actions, at least “institutional scaffolding” can be set up to support and engender responsible decisions.

Ethical decision making enhancement can either be formal or informal in nature. Formal systems often emerge as ethics policies or an established code of ethics guide and normalize decision making, but research indicates that these are far more prevalent in large corporations than in small businesses. Robertson (1991) found that 60% of the large firms in her study had a written code of ethics and 38% had ethics training programs. This finding stands in stark

contrast to small firms in her sample, where only 33% had a written code and a mere 7% had organized for ethics training. This difference suggests that decision making in large firms is more likely to be constrained by an established ethics framework, and thus its managers should be more ethical, and consistently so, than those of small companies.

In contrast, informal systems evolve naturally and are not so much a product of deliberate design. As a venture grows and develops, the founder gains managerial experience and additional managers are hired to join the enterprise. Decision making then becomes a group effort, and the focus shifts from a solo entrepreneur to a management team that that may be less likely to compromise its ethical standards to create gains that will flow toward someone else (in this case, the founder/owner). Also, with growth comes public accountability, professional management, and organizational norms and reward systems, all of which tend to shape decision making to be more consistent and more ethical. Taken together, these factors suggest that established (larger) firms will have a more developed sense of ethical standards, and the formal and informal systems to promote these standards.

**Agency Factors.** One of the distinctive features of small business is that there usually is no separation between ownership and management. When the firm grows and develops to the point where an agency relationship becomes necessary—i.e., the owner(s) decide to delegate decision-making authority to professional management—the dynamics of decision making inevitably shift (Jensen & Meckling, 1976). According to agency theory, this new arrangement opens the door to managerial opportunism, which is the risk that managers will make decisions that serve their own interests, often at the sacrifice of those of the owner(s). The misalignment of incentives

(managers working to maximize their compensation and other personal benefits while owners seek greater returns on their investment) can lead to a variety of problems (Jacobides & Croson, 2001).

The implications of agency problems for ethical standards in decision making are not readily apparent. On the one hand, the separation of ownership and management (especially if the firm goes public) may encourage the lowering of ethical standards. If a manager's sense of personal identification with the firm is not as great as a founder's, the incentive to compromise for the sake of increased compensation increases. But on the other hand, Morris et al. (2002) point out that as the founder develops as a manager and hires others to join the business, the focus often shifts from self-interest to ethical correctness, which may mitigate against the ethical downside of managerial opportunism. In any case, evidence exists to suggest that agency effects impact ethical perceptions. In a study of the ethical perceptions of respondents from both large and small firms, Longenecker, McKinney, and Moore (1989) found that agent/managers and owner/managers differed in their responses to 12 of the 16 scenarios in the researchers' questionnaire. Specifically, support for differences in ethical sensitivity was split between the two groups—owner/managers indicated higher ethical standards on six scenarios and lower standards on the remainder. As these findings illustrate, the impact of agency effects is not monolithic.

### **Summary of Ethical Theory**

Taken together, the personal and situational factors outlined above present a mixed picture of the influence firm size should have on ethical standards and practice. While features of the

entrepreneurial act itself and the tendency of entrepreneurs to lean toward machiavellianism suggest that small firms' decision making is likely to be *less* ethical, evidence of higher levels of cognitive moral development among entrepreneurs and the reputational and social capital they have at risk in their enterprises should lead them to act *more* ethically. The remaining factors (locus of control and need for achievement) seem to fall somewhere in between. Situational factors (environmental, institutional, and agency) argue more for lower ethical standards in small businesses, but the evidence is still quite equivocal. Overall, we see no overwhelming argument for or against higher ethical standards in small companies vis-à-vis their large firm counterparts, and therefore we intend to test the following research question:

*RQ2: Comparing responses of large and small firm executives across the 1985-2001 time frame, is there a discernable difference in their ethical standards?*

## **METHODOLOGY FOR BASELINE STUDIES**

### **Source of Primary Data**

Attitudes concerning ethical issues were probed in three nationwide mail surveys of managers and professionals in both large and small firms. The database used for analysis of our two research questions was based on surveys conducted in 1985, 1993, and 2001. In all three surveys, identical methodology was used. A questionnaire was sent to ten thousand individuals each year identified as business professionals by publishers of major business periodicals. A systematic sampling procedure was used by the mailing list vendor to generate the mailing list, excluding from the sampling frame anyone identified as a student subscriber.

## **Measurement of Ethics**

The six page questionnaire developed for our ethics research contained sixteen vignettes, each involving a business decision having ethical overtones. See Exhibit 2 for a list of the vignettes used in the 1985 survey. The dollar amounts included in Vignette A were adjusted upward in the 1993 and 2001 questionnaire to reflect inflation. Otherwise, the wording of all vignettes were identical from survey to survey. Respondents were asked to indicate the degree to which they found each action compatible with their own ethical views. They recorded their opinions by circling a seven-point scale ranging from 1 (never acceptable) to 7 (always acceptable). The midpoint on the scale, 4, was labeled “sometimes acceptable”; points 2, 3, 5 and 6, which were not labeled, represented intermediate positions between those defined.

The vignettes dealt with a wide variety of business situations and were designed to address ethical issues of varying loyalty in different functional areas of business. Some are clearly illegal, whether recognized as such by respondents or not, while others involve questionable or debatable ethical characteristics.

-----  
Insert Exhibit 2 about here  
-----

The use of scenarios or vignettes, according to Fritzsche and Becker (1982), permits one to inject more background information and detail into an ethically questionable issue. A questionnaire incorporating vignettes into its design, therefore, is thought to elicit a higher quality of data in this type of research than is possible from simple questions (Alexander and Becker, 1978). The

potential for systematic bias was minimized by having knowledgeable individuals assess the content or face validity of the vignettes prior to their inclusion in the questionnaire.

Additional questions classified respondents according to age, size of firm, employment level, and other customary survey classification variables.

Once the survey responses were accumulated, edited and entered into a database, an overall Ethics Index was computed for each individual by summing their responses to the sixteen vignettes and computing an arithmetic mean.

## **ANALYSIS AND RESULTS**

### **Responses to Surveys**

As can be seen in Exhibit 3, the response rates to the three surveys ranged from a high of 22.7% in 1985 to a low of 12.3% in 2001. We recognize the ever present possibility of non-response bias in databases when response rates are not near 100%. Unfortunately, financial constraints precluded the additional mailings that researchers sometimes use to build higher overall response rates. We would note, however, that response rates in and of themselves do not indicate whether the respondents are representative of the original sample (Malhotra, 1999). Furthermore, all analyses in this paper focus on differences in the sample. No claim is made that the means of the entire sample represent those of the sample population. Therefore, while a higher response rate would certainly have been desirable, for the analysis conducted here it is not crucial. We were encouraged that respondents came from every state in the United States and represented a wide range of management levels, professions, ages and business sizes, and that we do have large absolute numbers for all our analyses.

-----  
Insert Exhibit 3 about here  
-----

A brief profile of the three samples is shown in Exhibit 4. Notice that some characteristics, such as gender, were not identified in the 1985 survey. Size of the firm, which is one major focus in this paper was measured in each survey.

-----  
Insert Exhibit 4 about here  
-----

### **Analytical Techniques**

SPSS was used to analyze the data and to generate frequencies and other descriptive statistics. The ANOVA routine in SPSS for Windows was used to determine statistically significant differences between the Ethics Index measures.

### **Evaluation of Research Question 1**

In an earlier section we discussed the issue of overall change in the attitudes of business regarding ethics. We proposed the following research question:

*RQ1: For firms of all sizes, have business ethics improved or declined between the years 1985 and 2001?*

Exhibit 5 displays data representing the Ethics Index for all respondents by survey date regardless of firm size. As you can see, the Ethics Index for 2001 is mathematically less than the Index for 1993 and the 1993 Index is mathematically less than the one for 1985. An ANOVA F-test reveals that these differences are also statistically significantly different ( $p < .000$ ).

Remember, a lower Ethics Index value carries the meaning of a more ethical stance. *Our database shows a trend toward higher ethical standards over this 17 year period!*

-----  
Insert Exhibit 5 about here  
-----

## **Evaluation of Research Question 2**

Our second interest was whether we might see a difference in the ethical changes when we compared large against small firms. The research question stated again is:

*RQ2: Comparing responses of large and small firm executives across the 1985-2001 time frame, is there a discernable difference in their ethical standards?*

To address this question we compared the Ethics Index of large firm respondents (1,000 or more employees) with small firm respondents (100 or less employees). Exhibit 6 displays the Ethics Index scores for this comparison. Although there are slight mathematical differences in the 1985 and the 2001 surveys, they are not statistically significant. However, in the 1993 survey the Ethics Index for the large firms (2.42) is statistically different from the small firm Ethics Index (2.56). Note that the Indexes for 1993 indicate a more ethical stance among the large firms.

-----  
Insert Exhibit 6 about here  
-----

## **DISCUSSION AND IMPLICATIONS**

Our initial results suggest that business owners and managers are making more ethical decisions in recent times. The respondents show increasingly positive selections in their responses to the 16 vignettes across the time frame examined, as reflected in an Ethics Index. We also observed that small business respondents showed a propensity to be less ethical when responding to our vignettes in the 1993 study. Otherwise, there are no significant differences in responses between small and large firms.

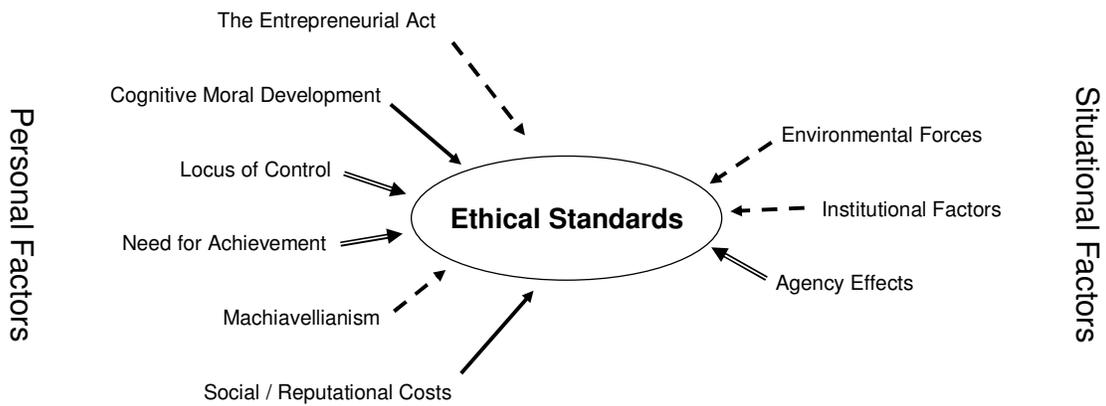

Given that the Ethics Indexes were significantly different between small and large firms only in 1993, and not in 1985 and 2001, we cannot draw a general conclusion that owners and managers of smaller firms are more or less ethical than executives in larger companies. Thus, we are left to conclude that personal factors and situational factors described previously may not always yield general differences in ethical values and behavior between leaders in small and large companies.

The fact that small owner/managed firms are very different from large corporations where ownership and management are separated, does not appear to result in different perceptions about ethical behavior. While the ethical values and inclinations of the small business owner should have a far more direct consequence on the practices of the business as a whole, they do not seem to be fundamentally different from their larger counterparts. Moreover, the findings suggest that the overlap of business relationships and personal networks of small company owner-managers do not lead to material differences in ethical behavior from managers in larger firms.

### **FUTURE RESEARCH**

Given the amount and richness of the data compiled over the 17-year time period, there is opportunity—and need—to extend the research. We believe several issues deserve attention. First, we can examine the informational content found in the individual vignettes, rather than relying only on an overall Ethics Index. In doing so, there may be differences that are not apparent in an overall index measurement. Second, we could use the data to compare the perceived pressures for managers/owners to act unethically and whether the pressures have changed over the 1985-2001 period overall and by firm size. This information should allow us to draw conclusion about the impact of situational factors in small versus larger companies.

**Figure 1. Personal and Situational Factors Impacting Ethical Standards**

*Note:* Arrows represent the nature of the impact for small firms. A negative linkage (dashed arrows) indicates that the factor has an unfavorable influence on ethics for small firms compared to large firms, while a positive linkage (solid arrows) shows a favorable impact for the same. Inconclusive effects are represented with double-lined arrows.

**Exhibit 2**  
**Ethical Vignettes Used in Survey**

- A. An executive earning \$50,000 a year padded his expense account by about \$1,500 a year.
- B. In order to increase profits, a general manager used a production process which exceeded legal limits for environmental pollution.
- C. Because of pressure from his brokerage firm, a stockbroker recommended a type of bond which he did not consider a good investment.
- D. A small business received one-fourth of its gross revenue in the form of cash. The owner reported only one-half of the cash receipts for income tax purposes.
- E. A company paid a \$350,000 “consulting” fee to an official of a foreign country. In return, the official promised assistance in obtaining a contract which should produce \$10 million profit for the contracting company.
- F. A company president found that a competitor had made an important scientific discovery, which would sharply reduce the profits of his own company. He then hired a key employee of the competitor in an attempt to learn the details of the discovery.
- G. A highway building contractor deplored the chaotic bidding situation and cutthroat competition. He, therefore, reached an understanding with other major contractors to permit bidding which would provide a reasonable profit.
- H. A company president recognized that sending expensive Christmas gifts to purchasing agents might compromise their positions. However, he continued the policy since it was common practice and changing it might result in loss of business.
- I. A corporate director learned that his company intended to announce a stock split and increase its dividend. On the basis of this information, he bought additional shares and sold them at a gain following the announcement.
- J. A corporate executive promoted a loyal friend and competent manager to the position of divisional vice president in preference to a better qualified manager with whom he had no close ties.
- K. An engineer discovered what he perceived to be a product design flaw which constituted a safety hazard. His company declined to correct the flaw. The engineer decided to keep quiet, rather than taking his complaint outside the company.
- L. A controller selected a legal method of financial reporting which concealed some embarrassing financial facts, which would otherwise become public knowledge.

- M. An employer received applications for a supervisor's position from two equally qualified applicants but hired the male applicant because he thought that some employees might resent being supervised by a female.
- N. As part of the marketing strategy for a product, the producer changed its color and marketed it as "new and improved," even though its other characteristics were unchanged.
- O. A cigarette manufacturer launched a publicity campaign challenging new evidence from the Surgeon General's office that cigarette smoking is harmful to the smoker's health.
- P. An owner of a small firm obtained a free copy of a copyrighted computer software program from a business friend rather than spending \$500 to obtain his own program from the software dealer.

**ABSTRACT**

Although a majority of all small and medium sized enterprises (SMEs) need advice the preparedness to accept advice among SMEs is often low. In what we call the formal institutionalized advice setting the SME owner finds him- or herself in a setting where the dispositions have been set before hand. In this system the main institutional context is that of standardization, formalized interaction and bureaucratic interaction processes. In this paper we investigate how banks, as one of the actors belonging to the formal institutionalized advice setting, are perceived as advisors by Swedish SMEs. The empirical material upon which our hypotheses will be tested emanates from a survey targeting the CEOs of 1130 randomly sampled Swedish SMEs with up to 200 employees. A total of 343 surveys were returned giving a response rate of 30.4 percent. LISREL, which is a structural equation modeling method, was used to analyze the survey data. The findings indicate that the failure of banks, and other actors belonging to the formal institutionalized advice setting, in providing advice can be found in the type of interaction they conduct with SMEs. These organizations are institutionalized in a way that does not correspond well to the type of behavior shown by SMEs. However, these actors have the potential to become better SME advisors. This could be achieved if the principles of non-standardization, non-formalization and personal responsibility were to be advocated and followed by those in charge of SME interaction in these organizations.

## INTRODUCTION

Advising is rarely easy for anyone, advising people, on touchy subjects, is even worse. Advisors to the owners of small-and medium-sized enterprises soon find that almost any subject can be touchy when the advice is geared towards the running of a lifetime achievement operation. The grand old man of Swedish banking Jan Wallander of Handelsbanken tells the story of when he, during a visit to a successful firm forty years ago, heard that the competitor had been thrown out of the firm in the harshest of manners. The competing banker had bluntly kicked on an old machine and muttered something about “poor resale value on that piece of junk”. Of course, that piece of junk proved to be the affectionate starting point for the entire enterprise. The preparedness to accept advice seems to be as important, or even more important, than the advisors competence in providing advice. A mediocre advisor can provide some clues to an interested listener, but not even the best advisor can reach a target that simply will not listen. And owners of small- and medium-sized businesses happen to have both extremely good reasons for listening to advice, and extremely good reasons not to listen. As for the reasons for SMEs listening to advice is the predominant feature that many owners of SMEs display an eagerness to find good advisors. One common craving for SME owners is for someone to listen and to provide, in fact, quite basic advice on how to act in different circumstances. Advice is a service that both relates to task-interactive and personal-interactive aspects, which requires close interaction to exist for a fruitful advising relationship to emerge (Bennett and Robson 2004). At the same time, running a small business requires a lot of self-confidence. Not every SME owner actually knows why he or she is successful, and they actually would prefer not to have someone criticizing their behavior. Especially since that critique would inevitably be taken as personal criticism. In general, SME owners are reluctant to listen to advice due to fear of losing control of their firm

(Storey 1994). In short, SMEs listen to advice in order to overcome the basic problem of learning more tricks to their trade (in research terms generally called the problem of information asymmetry (Nayyar 1990; Gallouj 1997)), but they prefer not to have the teacher using their role to suppress the free will and choice of the entrepreneur. Thus, advisors have to advise people who will eagerly listen if the right things are said, but that may suddenly lash out if the advice is seen as stinging critique of the listener. Apart from this, SME owners tend to listen to advice that is seen as personal, informal and provided in a way that the owner feels that the advisor has every reason to personally take responsibility for advice provided (Harvey and Fischer 1997 single out shared responsibility as a main propriety of why individuals take advice).

### **The formal institutionalized advice setting**

In what we call the formal institutionalized advice setting the SME owner finds him- or herself in a setting where the dispositions have been set before hand. There are in Sweden more than 40 different government agencies providing advice to small businesses. In addition, the major banks constitute a large part of the financing for smaller businesses, as business angels and other informal investors are scarce. Together these agencies and banks form formal institutions that tend to present advice in a way that most small businesses find themselves at trouble with. The formal institutionalized advice setting is characterized by high standardization in the advice provided, a formal protocol of how advice is provided and generally the officers in charge fail to personally take responsibility of the advice provided. Government agencies and banks are what may be termed as highly institutionalized in the vein of Meyer and Rowan (1977) in the sense that they are one part of a larger system infused with value. In this system the main institutional context is that of standardization, formalized interaction and bureaucratic interaction processes. The basis of action tends to be “legalism,

the mechanical following of rules and procedures without regard for purposes and effects” (Selznick 1996). These institutions typically use coercive power (DiMaggio and Powell 1983) based on rules in order to handle non-compliance, both within and outside of the organizations. Not surprisingly much of the research within the field of the new institutionalism has been conducted in government agencies and organizations (Tolbert and Zucker 1983; Meyer, Scott and Stang 1987) or on large corporations (Fliegstein 1985).

Among the government agencies in Sweden, Almi is the largest in terms of financing provided to small businesses. In conjunction with this they also provide advice, actually they demand that the SME owners accept their advice in order to receive the funding. Naturally, many SME owners regard this piece of advice as a necessary evil in order to obtain the capital, thus lowering their readiness to accept advice. Almi provides financing on top of bank loans and actually charge more in interest than the banks. The advice they provide is highly standardized as the SME owner needs to fill out a form based on a business plan. Even if business plans in themselves are quite handy for SMEs, they are in this case presented, as something the SME owner must do. Many SME owners find the entire process quite alienating. The government officer provides some advice, but is still, to the SME owner, an employee whose advice in all certainty is the same advice provided to every SME owner in the same type of industry. In other government agencies the same holds true, government officials provide standardized advice in a formalized fashion without really accepting personal responsibility for advice provided. Business firms in general tend to be reluctant towards the government in supporting firms on the basis that the help provided is deemed as not necessary, not suitable, and that government authorities in general can not be relied upon to provide continuous support (Fischer and Reuber 2003).

Swedish bankers are historically in the same category. During the last decades bankers have been on the offensive as bank deregulations have swept over the bank market.

The only practical effect of this has been that bankers tend to spend more time selling products. Again, from the SME owner perspective the bankers seem rather uninterested about their business. Some SME owners argue that bankers are rather cowardly figures hiding behind tons of bank regulations and refusing to provide any flexibility whatsoever. In any case, the story is virtually the same when it comes to the setting of the meeting between banker and SME owner. The banker is part of a banking institution, and provides a fixed set of products for the firms. It is the SME owner who has to adapt to the forms provided by the banker and to the standardized contract written out by the bank. If the banker takes a selling attitude, then the SME owner will be subjected to the same sales talk as every other SME owner who enters the bank. The bankers do judge the firms creditworthiness, and thus assess both strengths and weaknesses of the firm. But they usually will not discuss what they find out with the owner, other than perhaps presenting some conditions that may provide a clue as to what the problem may be.

Both government agencies and banks are organizations that model themselves after similar organizations in their field that they believe are more successful (DiMaggio and Powell 1991). In the case of government agencies advising SMEs, being successful means the ability to persuade the state to allocate more resources to the agency. For banks, successful to a large extent means a business that makes huge earnings while maintaining the goodwill of regulating authorities. In both cases inertia and herd behavior typifies the organizations in the field. In general, most SME owners feel at a loss when it comes to interacting in the formalized institutional setting. They constantly feel that they are subordinate to the requests of the institution. Either the SME owner accepts the preconditions and the standards set by the institution or they will have to leave. This way of force-feeding advice naturally makes the already reluctant SME owner want to leave the discussion. At the very least, any advice provided will be promptly disregarded.

### **The informal institutionalized advice setting**

There are advisors who seem at ease providing advice in a manner more fitting to the volatile mentality of the SME owners. Auditors in particular have a high reputation as sound advice providers by SMEs. It poses something of a problem due to the fact that the auditors providing the much sought after advice actually are not allowed to do so. A single auditor may not both provide advice and audit a specific firm at the same time. But in fact they do. When investigated it turns out that auditors provide advice in a most spectacular range of interests. They will certainly provide advice on taxation, or on ownership issues. They also provide advice on how to use computers to aid the SME operation. In addition however, auditors also provide advice on legal issues, marketing problems, negotiation practices, leadership issues, how to use external boards etcetera. Of course, auditors are paid by the hour and thereby have every incentive to idling their days providing advice to eagerly anticipating SME owners. But the fact is that the SME owners seem to appreciate the advice provided. A vital clue to understanding why SME owners appreciate the auditors apparently all-encompassing knowledge is the fact that in this situation it is the SME owner who decides what to talk about and when. This is important, as most SME owners tend to learn by doing, and thus appreciate to handle problems as they appear. The auditor simply answers the questions as best as he or she can, without standardizing responses, with no formal contracts and by accepting that poor advice may lead to a situation where the SME owner chooses to look for a new auditor. An interesting aspect on institutionalism is that the audit industry is an example of a profession that has been highly institutionalized over the years (DiMaggio and Powell identifies professions as typically highly institutionalized, see Scott 1985 as well). In the case of the audit industry, however, as is the case with medical professionals, lawyers and researchers, the institutionalism serves as protection from outside intervention. Thus, even if

auditors are highly institutionalized they are able to use this to safeguard their informal interaction with their customers, SME owners in particular. The audit industries practices to a large extent survive by seeking to minimize inspection from government supervisory authorities (see Meyer and Rowan 1991).

Other informal advisors include venture capitalists and business angels, who typically appear in the IT business and biotech industries. Venture capitalists in particular actually set a standard in the industries in which they work since most of them will only invest if the SME owner accepts advice. In these types of industries the SME owners all but have to accept external advice, as they often need venture capital to grow. Thus the initial skepticism towards external advice is abruptly shattered. The positive aspects are that the SME owners will be more open to external influence, the negative aspects include that the SME owners may see the firm as a short-term investment. In any case venture capitalists use different approaches in handling their customers. Some almost force advice upon their investment, others mainly stay in the boardroom, and some are actually heavily involved in the business. They always provide a mix of contractual aspects and informal agreements. Venture capitalists that provide standardized solutions and refrain from informal practical advice tend to be disliked by the SME owners in whose operations they invest. Some find venture capitalists to be stimulating if rather imposing advisors. At times venture capitalists have been referred to as vulture capitalists (Bygrave & Timmons, 1992). Many SME owners have difficulties with venture capitalists, but at least they take the dullness out of their life. Venture capitalism as an institution is an interesting phenomenon as the industry is far less regulated than either government agencies, the banking industry or the audit industry, and yet the industry is still tremendously influenced by management philosophy and herd behavior. Syndication behavior, incentive programs, the theories on inventors and entrepreneurs, all indicate a strong unifying bond within the industry. Business angels are basically all very

informal advisors and are generally as appreciated as auditors. Business angels are far less institutionalized than the other actors and represent an amazing variation in shape, size and form.

External boards are, when functioning properly, good venues for exerting professional, informal advice for SME owners. An external board consisting of benevolent and interested board members provides excellent opportunities for discussing the operations in the SME. The costs may seem prohibiting, but if the board is accurately set up the returns may prove to be very positive indeed. External boards that work best include people who foremost act as friends of the SME owner. It is beneficial to have professional expertise, but the simple and friendly assurance that a decision taken was correct seems to be even more important. The board meetings are places where, at their best, informal discussions take place where the SME owner can discuss matters that needs resolving and where there is an uncertainty in what is the best course of action. External board culture is to an extent institutionalized in the sense that it mimics the processes in larger corporations. Interestingly enough, since the board in an SME have far different purposes (mainly advice) than in larger corporations (owners safeguarding their investments).

In the informal institutionalized advice setting the SME owner finds a situation where he or she controls the tempo and where the advice provide is adapted to the circumstances faced at the time. The advisor clearly accepts some personal responsibility and refrains from using protocol or standardized solutions. In this environment most SMEs will accept advice provided. In cases where the set up seems ideal, but the SME owner will not accept advice, then in all likelihood the personal chemistry fails to work.

## **Institutional advisory competence**

The perception of what constitutes an able advisor is not entirely clear. In financing firms banks need to establish a format enabling them to provide products and advisory capabilities at a reasonable price. In a bank organization geared at providing reliable and relevant advisory functions for the firm, what may be called the enabling organization, the bank makes sure that the organization enables its frontline staff to provide advice applicable to the customer they are advising. Most banks as we have seen appear less than willing to provide informal advice. The institutional format of the bank lends itself toward formal interaction. As is always the case with large organizations there are always deviations to the norm. There are bank officers who emphasize problem solving rather than product sales, and these can be expected to generate a more positive response from SME owners. The perceived problem solving capacity can be seen as an effective measure of institutional advisory competence. In order to appreciate this kind of problem-solving the advice institutions shared knowledge needs to be specific enough for the SME to blend the advice with the SMEs own understanding of the situation (Chrisman and Mc Mullan 2004). As SME owners recognize the cost/benefit value of financial problem solving, the SME owners will appreciate high institutional advisory competence.

A high institutional advisory competence will result in two different strands of customer appreciation. Firstly, the institutional advisory competence will result in a high degree of interaction and flexibility in the encounter between the advising institution and the SME. Secondly, the institutional advisory competence will result in a high general customer satisfaction level. The above reasoning leads to the following hypotheses.

**H1:** We hypothesize that a higher degree of institutional advisory competence will be positively correlated to a higher degree of informal professional advice.

**H2:** We hypothesize that a higher degree of institutional advisory competence will be positively correlated to a higher degree of customer satisfaction.

### **Informal professional advice**

The interaction between an institution, in this case a bank, and SMEs is often characterized by a certain distance. However, these interactions have a potential to occur more frequently and result in more meaningful discussions if the advice delivered is perceived as relevant to the specific situation and needs of the firm, and if the advisor is perceived as someone to turn to when facing problems. The set up of the institution, the enabling organization, will result in its personnel being far more likely to generate positive outcomes in their dialogue with their customers. In an institutional setting characterized by informal provision of relevant advice, and where the advisor clearly shows that the SME owner can rely on the banker in harsher times, SME owners will generally create a favorable climate for communication between banks and SMEs.

As was stated previously the interaction at the meeting between SMEs and their advisor is crucial for the SMEs acceptance of external advice. If advisors behave in a way signifying that the SME is at the mercy of an infallible, rule-bound institution, the SME will generally refrain from interaction. Swedish SMEs normally act in an environment where informality and personal responsibility is at the core of trust-enhancing processes. SMEs tend to prefer to rely on personal interaction rather than strict contractual arrangements in relating to other SMEs and customers. In fact, many SMEs survive by their ability to provide deeper relationships than their larger competitors. In the meeting between two SME owners personal

trust plays an important role in cementing relationships (Chell and Baines 2000). The lack of time for networking activities means that for SMEs every encounter with outsiders is a potential networking enhancing activity, however they do shy away from activities that creates dependencies (Curran et al 1993). This creates a stark contrast to the environment in which an SME owner meets a strictly rule-bound official of a larger organization.

If SMEs do find informal personal advice they will invariably rely heavily on this environment to foster a high level of personal interaction. This interaction is the result of the SME opening up towards the advisor and engaging in a type of relationship that SMEs otherwise reserve for actors in their own environment. As the SME opens up to the advisor the advisor is granted access to additional information about the SME, which enables the delivery of accurate advice based on the firm specific situation. This will lead to a situation where the SMEs trust for the advisor increases further enabling the information exchange between the parties to improve. In the end this will lead to a situation where the SME perceives the relation as a partnership. This partnership is characterized by the SME perceiving the relation to the advisor to be close and personal as well as a perception of the advisor as a source of moral support. This leads to the following hypothesis.

**H3:** We hypothesize that a higher degree of informal professional advice will be positively correlated to a high level of perceived partnership.

### **Customer satisfaction**

General customer satisfaction in the case of SME owners facing advisory institutions depend upon the advisory institutions ability to provide a reasonable working environment. As long as the institution remains focused on what the SMEs perceive to be important points of departure for discussion the higher will the level of satisfaction be. In general, SME owners

prefer to discuss their financial situation from their own perspective. In order for an advisory institution to achieve a high mark in customer satisfaction its officers will need to display the ability to discuss the SMEs problem out of the SMEs own perspective. This is clearly not easily achieved, as it usually tends to be easier for bankers in this case to remain on safe ground and rely on procedures and product information in their interaction with the SME. To actually take a step out of the institutional role is a major one for many bank officers.

Customer satisfaction depends on the perception of the customer of intrinsic values in the relationships. Customers anticipating that the seller only has the capability to offer standardized solutions may be quite content to receive that. Many SMEs anticipate banks to offer only standardized solutions and rarely expect anything else. When confronted with the option to choose between advisors providing different sorts of settings for providing advice the differences are more profound. When comparing auditors with bankers nearly all SMEs will prefer their auditors as advisors. Even if both bankers and auditors generally work in large organizations, bankers will be referred to as “the bank”, whereas the auditor will be referred to as “Mr. Knowles”. That SMEs typically prefer the latter type of relationship is augmented by the large amount of literature pointing out the importance of social networking for SMEs, especially in weak tie relationships (Aldrich and Zimmer 1986; Bryson et al 1993). In an advisory situation customer satisfaction seems to be directly correlated to level of formalization.

The customer satisfaction level stems from an ability to recognize the ability of the advisor to actually portray themselves as partners rather than sellers in the interaction. Customer satisfaction will thereby be a crucial ingredient in promoting a high level of personal interaction. The above reasoning leads to the following hypothesis.

**H4:** We hypothesize that a higher degree of customer satisfaction will be positively correlated to a high level of perceived partnership.

## **METHODOLOGY**

The empirical material presented in this paper emanates from a survey targeting Swedish small and medium sized enterprises (SMEs). As we have already mentioned there are a vast number of advisors that in many cases, at least partly, focus on providing advice to SMEs. However, for the purposes of this study, the empirical data upon which our hypotheses will be tested concerns how SMEs perceive banks as advisors. Since SMEs are the target a definition of what constitutes a small firm, for the purposes of this paper, is needed. There appears to exist a lack of actual consensus regarding the definition of what constitutes a small and medium sized firm. Different researchers have been known to use differing definitions (Storey, 1994). Earlier Swedish research (Davidsson, 1989) has defined small and medium sized enterprises as independent firms with 200 or fewer employees. As regards surveys, a common way of defining SMEs is to use some sort of size measure such as number of employees or turn over. Even though other measures than number of employees occur our definition of small and medium sized enterprises will in this study be, Swedish privately owned firms with up to 200 employees that are not part of a corporate group, a definition also in line with contemporary research on SME's in Sweden as well as abroad (Cressy and Olofsson, 1997; Storey, 1994; Wiklund, 1998).

### **The survey and the sample**

The random sampling of the firms was made by Statistics Sweden. A total of 1130 Swedish companies, with up to 200 employees, were chosen. A further criterion for the random

sampling was that the firms had to be stratified not only with regards to industry but also to size.

The target for the questionnaire was the CEOs in the small firms. According to Oppenheim (2003) some of the main disadvantages associated with questionnaires are low response rates and response biases. In order to improve the response rate a few approaches were used that have been found to increase response rates in the past (Oppenheim, 2003). Accompanying the questionnaire was a covering letter. The covering letter included, among other things, explanations of the purpose and context of the study and an introduction of the researchers and their institutions. Furthermore, the covering letter also included comments on the issues of confidentiality and the possibilities for (interested) respondents to get a summary of the results of the study. In a further attempt to improve the response rate a reminder was sent out to the firms who did not answer the questionnaire the first time. This reminder was sent out 4 weeks after the first questionnaire had been sent out.

A total of 343 surveys were returned giving a response rate of 30.4 percent. Two drop out analyses were performed in order to check for possible biases among the respondents. First, when the companies were selected for the sample background data was obtained on their characteristics from Statistics Sweden. Consequently, the first analysis consisted of comparing respondents with non-respondents as regards size, main industry, start week and municipality code. We could not, however, find any statistically significant differences between the respondents and non-respondents. The second dropout analysis consisted of using a method put forward by earlier researchers who argued that late respondents and non-respondents share many of the same characteristics (Armstrong and Overton, 1977). Therefore the sample was divided into early and late respondents enabling a comparison of

the two groups of firms. We were unable, however, to find anything that could indicate a statistically significant difference between the groups.

### **Analysis using LISREL**

LISREL, which is a structural equation modeling method, was used to analyze the survey data. Structural equation modeling, which is a way of studying causal effects in a data sample (Jöreskog & Sörbom, 1993), has recently been used in small business research (Bennet & Robson, 2004; Soriano, 2001). The use of structural equations modeling enables the investigation of causalities in real business settings instead of having to infer them by the logic of arguments (Jöreskog & Sörbom, 1993). The creation of a LISREL model involves two steps. The first step consists of the identification of latent variables, in structural modeling referred to as constructs. A construct captures underlying commonalities of a set of indicators and is thus a variable of a higher order and more abstract than the indicators related to it (Jöreskog & Sörbom, 1993). In the second step causal relations between the constructs are defined in a structural model (Eriksson et al, 1997).

The validity of the constructed LISREL model is estimated by testing for nomological, discriminant and construct validity. Nomological validity, refers to the validity of the entire model, and is assessed by the  $\chi^2$  and degrees of freedom measure, together with a probability estimate ( $p$ -value) (Jöreskog & Sörbom, 1993). Although there are no definite threshold values for  $\chi^2$  and degrees of freedom it has been argued that the fit is good when the values of  $\chi^2$  and degrees of freedom are roughly the same (Jöreskog & Sörbom, 1993). However, other authors argue that such a rule of thumb can be difficult to apply and that a  $\chi^2$  that is lower than the value of the degrees of freedom is acceptable. The value of  $\chi^2$  should not, however, be

substantially higher than the degrees of freedom value. As regards the probability estimate the  $\rho$ -value of the model should be 0.05 or higher to indicate a non-significant distance between the model and the data at the 5% level.

According to Jöreskog and Sörbom (1993), a number of other statistical measures that enable assessment of nomological validity exist but they are all functions of  $\chi^2$ . Some of the most frequently used measures are GFI, RMSEA and CFI. The first measure, GFI, or goodness of fit index, checks for sample size effects and should be above 0.90. The RMSEA, or root mean square of approximation, measures population discrepancy per degree of freedom, and should be below 0.08. The CFI measure, or comparative fit index, checks for non normal distributions and should be above 0.90.

The second validity test is discriminant validity, which consists of an assessment of the separateness of the constructs (Jöreskog & Sörbom, 1993). Discriminant validity is assessed in two ways. First, we make sure that the constructs are separate and not correlated to each other. This is done by forming an approximate confidence interval by taking the standard error term times two (Anderson and Gerbing, 1988; Jöreskog and Sörbom, 1993). All values that fall within this interval are not significantly different from the correlation coefficient. The second way of controlling for discriminant validity is performed in cases when the  $\rho$ -value of the model is non significant. This is done by investigating the modification index in the LISREL software. This index suggests changes in the model if the indicators are related to more than one construct.

The final test for validity is convergent validity. This test checks for the homogeneity of the indicators and their constructs and is assessed by looking at three estimates: coefficients, t-

values and R2-values. The coefficients normally referred to as factor loadings, reflect the strength of the relationship between two variables (Bollen, 1989). According to Jöreskog and Sörbom (1993), there are no definitive limits for factor loadings, instead the numbers should be judged in association with theoretical considerations. If the theory suggests a weak relationship then a low coefficient is acceptable. The t-value is a standard estimate of statistical significance and should be 1.96 or above to be statistically significant at the 5% level. Finally the R2 value is an estimate of the strength of the linearity in a relationship. Although there are no definitive threshold values of what constitutes an acceptable R2 value, as in the case with coefficients, an R2 value of 0.20 or above indicates an acceptable linearity of a relationship (Jöreskog & Sörbom, 1993).

In order to account for missing values pairwise deletion was used. The number of missing values ranged from 1 to 7, depending on the indicator. The results were also tested by listwise deletion with similar results (See Appendix, Correlation Matrix).

## **RESULTS**

The first assessment of the model regards its convergent validity, which is analyzed by using the factor loadings, t-values and R2 values. These values are presented in table I. The correlation matrix for the constructs, including error terms and t-values for the constructs, is presented in table II in the appendix.

---

Table I about here

---

The construct “Institutional advisory competence” represents the banks knowledge about its SME customers. Two indicators were used to capture the Institutional advisory competence construct. The first is the perception of whether the bank is able to provide financing at reasonable conditions; that is if the bank provides good value for money (factor loading 0.79, t-value 23.61). The second indicator regards the banks competence in solving financial problems for SMEs (factor loading 0.88, t-value 25.96). The values suggest good convergent validity for the construct.

As in the case with the first construct we have again used two indicators to capture the “Informal professional advice” construct. The indicators concern the respondents evaluation of the banks ability to give good advice (factor loading 0.79, t-value 19.92), and their evaluation of whether they can turn to the bank in times of trouble (factor loading 0.92, t-value 34.63). Again the values suggest good convergent validity for the construct.

The “Customer satisfaction” construct consists of one indicator. The construct is meant to capture the SMEs overall level of satisfaction with the bank. Since the question directed to the respondent is direct it is assumed that it captures the respondents perceived level of satisfaction with the bank in a clear way.

The final construct, “Perceived partnership”, is intended to capture the SMEs perception of whether the relation to the banker can be characterized as a partnership in terms of closeness and if the bank provides moral support. The construct consists of two indicators. The values of the first indicator, the perception of having a close relation to the banker, are 0.78 for the

factor loading and 19.20 for the t-value. As regards the second indicator, the perception of whether the banker is a source for moral support, the values are 0.95 for the factor loading and 29.21 for the t-value respectively. The values suggest good convergent validity for this construct as well.

The model was also found to be discriminantly valid in that the constructs are separated from each other. Firstly, the modification index of the LISREL software did not suggest any changes in the model, which means that the indicators are not related to more than one construct. Neither did the approximate confidence interval, which is computed by taking the standard error term times two, for the coefficients in any case include the value 1 (See Appendix, Table II).

Figure 1 shows the structural model in its entirety. The model illustrates the relations between Institutional advisory competence, Informal professional advice, Customer satisfaction and Perceived partnership as well as the relations between the constructs and their indicators. The results of the analysis indicate that the model is nomologically valid, in other words, the entire model holds together. The model has a p-value of 0.209, an  $\chi^2$  of 14.45 and 11 degrees of freedom. As regards the other measures GFI, RMSEA and CFI the values were in these cases 0.98 for GFI, 0.030 for RMSEA and 0.99 for the CFI. These values also indicate a good fit between the model and the data. The model shows that the causal relations between Institutional advisory competence and Informal professional advice (0.85, 14.72), and between Institutional advisory competence and Customer satisfaction (0.64, 11.20) are positive and strong, thus supporting Hypotheses 1 and 2. The model also shows that the Perceived partnership construct is influenced by the Informal professional advice construct (0.49, 6.29) as well as the Customer satisfaction construct (0.24, 3.28), which supports

Hypotheses 3 and 4. Furthermore, the analysis shows that there is no direct relation between the Institutional advisory competence and the Perceived partnership construct. The construct of Institutional advisory competence operates only via the Informal professional advice and Customer satisfaction constructs.

### **FINAL ANALYSIS**

The final model of analysis shows that advising SMEs successfully requires an interlocking scheme of activities on part of the advisor geared at conveying a sense of understanding for the SMEs situation. In order to create a fruitful advisor relationship it is impervious for advisors to create an understanding based on the fact that the advisor will in fact take personal responsibility for advice provided. In addition, the advisor needs to make sure that the advice is perceived as problem-solving for the individual firm in question, merely advising in the same manner for thousands of similar firms of equal size and shape routinely will not build strong advisor relationships. Finally, the degree of formalization is an aid in transferring advice in a manner that is easy to digest for the SME owner. When stated like this it all seems to make perfect sense. However, in practice, government authorities and to a large extent banks fail in providing advice based on these simple principles. In the end, both government authorities and banks have a hard time finding trust among SMEs. Some may say that this is due to the nature of the business. That small enterprises generally do not trust larger enterprises. A statement that does not sound all that great when comparing SMEs relationships with bankers belonging to large enterprises and relationships with auditors

belonging to large enterprises. It may also be argued that small firms do not trust financiers. But in fact they do, especially private investors such as business angels.

Our analysis is that the failure of government agencies and banks in providing advice can be found in the type of interaction they conduct with SMEs. These organizations are institutionalized in a way that does not correspond well to the type of behaviour shown by SMEs. In terms of research the institution of government agency and the institution of the banking industry utterly fails to match with the institution of SMEs. These institutions are simply ill equipped to understand each others needs. The audit industry has taken upon their own to shield themselves from outside influence from supervisory authorities and thereby manages to interact better with SMEs. It is hard to imagine either the government agencies or the banking industry institution to change in order to better fulfill their role as advisors. Either they will continue as rather poor advice options for SMEs, apart from a small number of independent-minded bankers, or they will have to find a way to improve their way of communication with SMEs.

### **MANAGEMENT IMPLICATIONS**

The management implications of this study are to suggest that in fact both banks and government authorities can become better SME advisors. This could be achieved if the principles of non-standardization, non-formalization and personal responsibility were to be advocated and followed by those in charge of SME interaction in these organizations. In order to achieve such a goal the officer in charge of interactions with SMEs needs to have a position of flexibility and a supporting organization.

Non-standardization is best achieved if the organizations supporting officers in charge of SME interaction refuse to authorize specific manuals and instructions for how these officers are going to relate to SMEs. Instead the officer needs to be fully knowledgeable about

the SME perspective, and able to actually analyze a SME out of it's own perspective. In addition, product sales should be downsized in favour of general sales targets. In this way, officers will not be tempted to go for simple short-term solutions.

Non-formalization can be achieved by lowering demands for SME owners to fill in specified forms in order to interact with the advising institution. The comparison between auditors and bankers are profound in the way that bankers make SMEs fill in the forms where auditors tend to do fill them out themselves. SME owners are by their very nature quite uninterested in financial solutions, they would preferably like to be guided through the system. Guided, however, not necessarily forced-marched through a pre-specified route.

Personal responsibility is absolutely crucial in gaining the trust of SME owners. Both government officials and bankers tend to hide behind their rules and regulations in order to maintain a low profile in relating to SME owners. In the end the SME will, entirely correctly, assume that they are dealing with the henchmen of an uncaring colossus of an organization where a tiny SME counts for nothing in the end. It will in all probability not be enough for government authorities and bankers to appoint "personal bankers", as no SME owner will fall for such an easy lure. Instead these organizations must attempt to actually find a way to encourage and emphasize a genuine personal responsibility.

In the end many SMEs need advice. SMEs furthermore need an array of potential advisors, instead of having to rely on a single source. This need is accentuated by their need to overcome their natural reluctance to accept external advice. If the advisors show enough commitment to persuade the SME owners of their genuine benevolence, then SMEs will be able to share information more readily, to the benefit of all concerned.

## APPENDIX

**Table II.**

The coefficients between the constructs, error terms in parentheses and t-values.

| <b>Constructs</b>                 | Institutional advisory competence | Informal professional advice | Customer satisfaction   | Perceived partnership |
|-----------------------------------|-----------------------------------|------------------------------|-------------------------|-----------------------|
| Institutional advisory competence | 1.00                              |                              |                         |                       |

## **ABSTRACT**

SMEs and their associated entrepreneurship are currently the focus of considerable policy and academic interest globally. They are major contributors to job creation, economic growth and development in an economy.

Previously Tanzania pursued a socialist approach to development. This has failed there, as in most other countries. Consequently, since the 1990s Tanzania has started to focus on actively promoting entrepreneurship through new venture creation at the SME level as a way of fast-tracking its economic development.

Human capital is a critical input to the development of firms and nations. A lack of human capital can hinder development just as a shortage of physical capital. This study examines the influence of human capital elements of entrepreneurs and workers on the performance and conduct of new small manufacturing firms in Tanzania over the period 1997 – 2001. Relevant data was collected by means of questionnaires administered to a nationally-drawn sample of 200 firms, obtained by random selection procedure. Performance is measured in terms of growth in real sales. Multivariate regression and Cobb-Douglas production function analyses were undertaken and these confirm that human capital of both labour and the entrepreneur together with physical capital are critical predictors of performance, with evidence of increasing returns.

Business conduct is examined in terms of recruitment practice, training of employees, keeping of records and access to bank financing. The results show that small manufacturing enterprises with more educated and trained entrepreneurs are better in all conduct attributes under study relative to their less educated or trained counterparts. The policy implications are clear. If Tanzania wants more output, employment and growth, this would not happen through the socialist route. Instead the way forward is through vigorous entrepreneurship as reflected by venture creation and a strong small-firm manufacturing sector with caring concerns for empowerment of both labour and the entrepreneur.

## INTRODUCTION

Tanzania adopted a socialist approach to its development after gaining independence from Britain in 1961. Manufacturing industries, banks, insurance, wholesale trading, medical care and agriculture and other activities were nationalized and farms organized as collectives. With its implementation of the 'ujamaa' development strategy, living conditions in Tanzania did not progress. Government ownership of most enterprises coupled with a distrust of private sector initiatives led to a collapse of the Tanzanian economy in the 70s and part of the 80s and to rising poverty (Paulson and Gavin, 1999: 61). Macroeconomic instability, rising unemployment and worsening living conditions forced the Tanzanian government to abandon its socialist strategy and adopt reforms coupled with World Bank structural adjustment programmes to revive its economy. An important measure of the revival strategy was the promotion of entrepreneurship which began in the 1990s. Tanzania thus started to focus on developing SME entrepreneurship as a way of fast-tracking its economic development.

There can be no private entrepreneurial activities without entrepreneurs and it is through their value-adding activities that individual and national prosperity can be obtained, particularly in terms of economic growth, development, innovation, tax revenue and employment generation. Entrepreneurship flourishes in a market-oriented environment, favourable to employment of human and physical capital by entrepreneurs, and in which there is respect for law and order, property rights, good governance and incentives to risk-taking activities. A lack of human capital can hinder development just as a shortage of physical capital. Against this background, this paper examines the influence of human capital elements on the development of small and micro manufacturing firms in Tanzania.

The paper consists of five sections. Section one briefly covers the nature and significance of human capital to development. Section two examines the research design. Sections three and four present a discussion of the findings and this is followed by some policy recommendations.

## HUMAN CAPITAL ELEMENTS

Human capital plays an important role in the economic and social development of a nation. It enhances workers' and entrepreneurs' ability to exploit business opportunities, to work smarter and to improve business performance. According to Schultz (1975: 833), human capital enhances the individuals' efficiency in responding to changes when they work for the market or even carry out household activities. Employees who invest in education and training will raise their knowledge and skill, be more productive, and earn higher wages than the less skilled (Becker, 1993:24). Better knowledge and human capital improves individual and organizational efficiency and this generates positive externality benefits to economy.

In the traditional Keynesian analysis, much emphasis was placed on physical capital, relative to human capital, as the driving force behind output growth. Entrepreneurship was regarded as part of the residual factor in the growth analyses. In recent times,

however, the literature based on the pioneering works of Milton Friedman, Theodore Schultz, Jacob Mincer and Gary Becker, together with those of other economists and management scientists have shown that investment in human capital is critical to the generation of economic growth and productivity of nations. In effect the endogenous growth models have further brought the human capital to the forefront of wealth creation process (Romer, 1966; Lucas, 1988; Hall and Jones, 1999; Artadi and Sala-i-Martin, 2003).

Physical capital is therefore necessary but not sufficient to generate economic growth. Skilled workers, managers, and entrepreneurs are needed to operate machines, manage the production and distribution of goods and services, develop new products and new production methods, and utilize innovations (Becker, 1995: 1). The pouring of physical capital into developing countries during their post-independence years did not show much positive results. This implies that at a certain level, human capital needs to be matched with non-human capital; otherwise a low level of human capital development becomes a limiting factor in economic growth.

Researchers have been somewhat reluctant to analyse the contribution of human capital to organizational performance and economic growth, due to measurement difficulties Schultz (1961:7). Measurement of business performance often varies from one firm to another. Financial and accounting measures as well as time frames are used in varying ways. Although measurement issues of human capital are problematic, it is important to specify key human capital dimensions, assess their characteristics, and examine their impact on organizational performance.

Human capital encompasses learning, education, training, health care expenditure and any other form of expenditure that increases productivity of an individual and the performance of the firm (Burger, 2003). Becker (1993:43) claims that human capital can take the form of skills and abilities, personality, appearance, reputation and appropriate credentials.

Certain skills may be acquired while an individual performs an activity, such as a production process, or solves a problem – learning by doing (Arrow, 1962: 156). Human abilities can be either innate or acquired. Griffin and Knight (1990:38) stress that through long-term human resource policies, countries can enhance the capabilities of their people to do more things and lead fuller lives. In this regard, emphasis should be placed not only on national income per head or its distribution, but also on investment on relevant education and training.

Lucas (1988) and Shane (2003:75) argue that human capital formulation is a spin-off effect of production, and experience is the major source of acquiring knowledge and skills. Experiential learning contributes to enhanced productivity (learning effect). The learning effect, taking place consciously or unconsciously, manifests itself when the time expended in production is a decreasing function of the cumulative number units produced. Schultz (1963:8) identifies five main elements of human capital: health, migration, on-the-job training, formal education, and experience.

A 'new' aspect of capital in the modern entrepreneurship literature relevant to venture development is social capital. This refers to the entrepreneurial competence in terms of networking relationships, exercise of trust, reciprocity, conflict resolution, focus on team goals, and exchange relations with others (Bridges et al, 2003:95). While acknowledging the significance of social capital, this study does not examine this variable. However, the influence on another variable on enterprise performance is considered- n-Ach level of the entrepreneurs. N-Ach is described as a desire to well so as to obtain an inner feeling of personal accomplishment or to be successful in competitive situations (Mahadea, 1994: 95). McClelland (1961) associates n-Ach with a desire for personal responsibility, problem-solving, moderate goals and risk-taking, and concrete feedback on performance. The n-Ach levels of individuals and hence the supply of effective entrepreneurs can be enhanced through appropriate training, experience and schooling (Holmes and Schmitz, 1990).

For the purposes of this study, human capital is defined as the knowledge, skills, competence, and other attributes embodied in entrepreneurs and workers, through education, training and experience that are relevant to economic activity. An entrepreneur is regarded as someone who has, individually or jointly, started up a business enterprise and is running the venture (for at least 5 years).

## **METHODOLOGY**

Relevant data were gathered through interviews and questionnaires administered to a sample of 200 small-scale manufacturing entrepreneurs. They were randomly selected from the list of registered firms operating in Tanzania and proportionately drawn from 18 regions of mainland Tanzania. The data were analysed using SPSS.

The subjects were 200 indigenous business persons, 173 males and 27 females, aged between 19 and 65. Of the surveyed entrepreneurs, 33 engaged in tailoring and sewing, 43 in edible food, another 43 in woodwork, 51 in metalwork, 24 in leatherwork and 6 in animal food processing. The subjects' n-Ach level was measured by using the Mehrabian scale of achieving tendency (1975). This instrument consists of a set of 26 questions that is administered to male and female respondents, measured on a nine-point scale from +4 to - 4. The overall n-Ach score of each surveyed entrepreneur was obtained by adding up the scores of each question. A higher positive value indicates a greater nAch level, and the reverse is also true.

This study uses multiple regression analyses and a Cobb-Douglas production function to examine venture performance, with output, proxied by real sales (after discounting for inflation) as the dependent variable and the entrepreneurs' nAch, education, training, experience, and employees' education and training as well as physical capital, as the independent factors. Generally firms with more physical and human capital tend to perform better than those with less of these inputs. Education, training and experience

were measured in years, and output and physical capital were expressed in the Tanzanian currency (Tzs).

The independent variables were initially regressed on output growth using OLS. A parsimonious model was initially arrived at, but it did not satisfy the assumptions of OLS, and the role of the entrepreneur was found to be insignificant in the enterprise, making the firm seemingly entrepreneurless. Accordingly, to overcome this limitation, the set of data relating to the dependent and independent variables was transformed logarithmically, and an alternative model based on a Cobb-Douglas production was developed. Residuals of the predictors after transforming the data logarithmically were also plotted. The model gave a better fit, which seems not to violate the 'homoskedasticity' assumption.

## FINDINGS

### Parsimonious multiple regression model

In accordance with economic theory, it is hypothesized that physical capital and the human capital of workers and entrepreneurs coupled with physical capital can predict venture performance and the beta coefficients of the independent variables are, therefore, expected to be positive.

SPSS's backward linear regression approach was used to arrive at an initial model that 'best' explains enterprise performance. This entails entering all the independent variables in the model, and then removing the 'weaker' ones in subsequent stages, according to certain criteria. The basic criterion is to retain the independent variable that has a high explanatory influence, usually shown by a t-value that is statistically significant. Koop (2000: 88) argues that it is a common practice to initially use as many explanatory variables as possible, and then discard those that are not statistically significant.

Using the above approach, four variables were found to be significant: capital, employee education, employee experience, and employee training. The results of the fitted regression model are summarized below.

$$\text{Sales} = -120857.2 + 0.308(\text{Capital})_{t=4.661} + 0.290(\text{Employee education})_{t=4.802} + 0.292(\text{Employee experience})_{t=4.93} + 0.154(\text{employee training})_{t=2.36}$$

$$\text{R-square} = 0.343$$

$$\text{Adjusted R-square} = 0.329$$

$$\text{F-value} = 25.4$$

$$\text{N} = 200$$

t = t-value, statistically significant at the 5 % level of significance

The role of the entrepreneur is critical to the formation and performance of any firm. But the above model, although explaining about a third of the variation in output, does not capture the influence of the prime decision-maker (entrepreneur) in the development of

the manufacturing firms. It simply shows the influence of employee human capital and physical capital as significant predictors of venture performance.

To overcome this limitation, an alternative and preferred regression model was developed based on a Cobb-Douglas production function. The absence of the significance of entrepreneurs in a model is tantamount to ‘Hamlet without the Prince of Denmark’.

### **The preferred model**

Parametric methods assume that the sample is drawn from a population where values have a normal distribution. The above regression model did not satisfy the OLS assumptions of normality and homoskedasticity (error terms having equal variances). This is evident from the shape of the histogram of residuals.

To overcome the technical inadequacy and heteroskedastic limitation, an alternative model was developed to predict venture performance, with the earlier data relating to the dependent and independent variables, being transformed logarithmically.

Using OLS method, the double-logarithmic transformation gives a regression model of the following form:

$$\text{Log } Y = \alpha + \beta_1 \log(X_1) + \beta_2 \log(X_2) + \beta_3 \log(X_3) + \dots + \beta_n \log(X_n) + e$$

where

|                                    |  |
|------------------------------------|--|
| Y                                  | = Output   |
| $\alpha$                           | = Intercept  |
| $\beta_1, \beta_2, \dots, \beta_n$ | = Elasticities of output with respect to independent variables |
| $X_1, X_2, X_3, \dots, X_n$        | = Independent variables, and                                   |
| e                                  | = error term   |

The new model could be viewed as a multiplicative relationship between sales and the selected variables. Considering sales of the surveyed manufacturing ventures as a proxy of output, the above logarithmic function could be converted into a power function, often referred as the standard Cobb-Douglas production function.

$$Q = aX_1^{\beta_1} X_2^{\beta_2} \dots X_n^{\beta_n}$$

where

Q = Total output (real value of sales)

$X_1, X_2, \dots, X_n$  = Independent variables

$\beta_1, \beta_2, \dots, \beta_n$  = Output elasticities of  $X_i$

To arrive at the preferred model, all independent variables were again initially entered, and then through the backward elimination procedure, sequentially a weaker variable was excluded until all the remaining predictors are found to have statistically a significant contribution to venture performance. In this case, the entrepreneurs’ nAch and experience, employee education, and number of employees were found to be not significantly contributing to the model, and were thus excluded in stages until the ‘best’ model was reached (presented in table 1).

[Insert Table 1 here]

The developed model can be presented as follows:

$$\begin{aligned} \text{Log(Output)} &= .243 + .481\log(\text{capital})_{(t=7.409)} + .571\log(\text{entrepreneur education})_{(t=2.851)} + \\ &1.039\log(\text{employee experience})_{(t=9.551)} + .221\log(\text{employee training})_{(t=1.929)} \\ &+ .135\log(\text{entrepreneur training})_{(t=2.189)} + \text{error term} \\ \text{R-squared} &= 0.511 \\ \text{Adjusted R-squared} &= 0.499 \\ \text{F-value} &= 40.495 \end{aligned}$$

The results clearly indicate that output is found to be influenced by physical capital, entrepreneur education, entrepreneur training, employee experience, and employee training. A summary of the preferred model with collinearity diagnostics is presented in table1. The estimated coefficients 0.481, 0.571, 1.039, 0.221, and 0.135 refer, respectively to output elasticities of capital, entrepreneur education, employee experience, employee training, and entrepreneur training

From the above, the following deductions can be made:

- Output is likely to increase by about 5% for a 10% change in capital
- Output is likely to change by about 6% for a 10% change in entrepreneur education
- Output is likely to increase by about 10% for every 10% increase in employee experience
- Output is likely to increase by about 2% for every 10% change in employee training and
- Output is likely to change by about 1% for every 10% change in training of the entrepreneur.

Since the sum of elasticities (2.447), is greater than 1, there is evidence of increasing returns to scale in manufacturing firms. This implies that an increase in capital, entrepreneur education and training, employee experience and employee training by 10% is likely to cause output to increase by a greater amount, almost 25%.

The developed multiple regression model has the following strengths:

- It explains more than 50% of the variation of sales (R square = 0.511, adjusted R square = 0.498).
- Overall, the model is statistically highly significant (F = 40.495; p = 0.000).
- The elasticities of almost all variables are significant at 5% level.
- The histogram of residuals shows a normal curve, implying that the technique used and OLS assumptions for multiple regression analyses were satisfied.
- The model captures human capital elements of both the entrepreneur and labour, and physical capital- all found to be significant predictors of manufacturing enterprise performance.
- The model can be converted into a power function, allowing marginal production of a given predictor to depend on all other variables in the model, a condition that usually holds in real life situations.
- Overall the results accord with and support the human capital theory.

## HUMAN CAPITAL AND CONDUCT OF MANUFACTURING VENTURES

With regard to conduct of business, the results show that small manufacturing enterprises with more educated and trained entrepreneurs tend to employ more educated workers, keep more business records and have greater access to finance from banks than their counterparts with lower levels of human capital. Further, business individuals with more accumulated human capital tend to be more entrepreneurial in that they are more likely to own another business.

## RECOMMENDATIONS AND CONCLUSION

This study clearly shows that physical capital is necessary but not sufficient for the development of manufacturing firms. Critical also is the knowledgeable, skilled and experienced human factor. The accumulation of entrepreneurs' and workers' capital operating jointly in a production function with physical capital can propel the small Tanzanian manufacturing firms into a virtuous spiral of sustainability and success, so long as they competitively meet the needs of the market. Increasing returns to output are likely to emerge from an increase in investment in human and physical capital.

If Tanzania wants more output, income and employment expansion, this would not happen through the socialist route. Instead, the way forward is through entrepreneurship, as partly reflected by a strong manufacturing sector with caring concerns for capital investment and human empowerment. An educated or trained entrepreneur is a more productive business person. Likewise a skilled workforce is a more productive labour, capable of adjusting fast to industrial and technological changes in a global environment. In order to enhance its economic growth, Tanzania cannot afford to neglect neither physical capital nor human capital. Evidently this has wider implications with respect to education, training and experience and institutions at the firm and national level.

**Table 1: Summary for the developed model (Cobb-Douglas production function)**

| Model | R    | R Square | Adjusted R Square | Std. Error of the Estimate |
|-------|------|----------|-------------------|----------------------------|
| 1     | .715 | .511     | .498              | .47742                     |

**KEEPING IT IN THE FAMILY: INVESTIGATING THE IMPACT OF IDENTITY  
AND CEO FAMILY TIES ON FAMILY COMMITMENT**

**ABSTRACT**

Drawing upon psychological ownership theory, social identity theory, kinship theory, the upper echelon perspective, and commitment literature, this study proposes a model of family members' identification with their family's business. We argue that social factors such as family representation in the top management team, family and shareholder meetings, and percentage networth invested in the business will determine perceived identification with the business, which, in turn, affects family members' commitment to continue the family business. We further propose that these relationships are influenced by the CEO's ties to the founding family. A structural equation model of these relationships is cross-validated using data drawn from two large-scale, national surveys of family businesses.

# **KEEPING IT IN THE FAMILY: INVESTIGATING THE IMPACT OF IDENTITY AND CEO FAMILY TIES ON FAMILY COMMITMENT**

## **INTRODUCTION**

Researchers suggest that a primary goal of family business owners is to pass the business on to another family member (Casson, 1999; Ward, 1991). Associated with the desire to pass on the business, the family is said to bring a long-term perspective in the business that emphasizes firm survival over short-term performance (Anderson & Reeb, 2003a). While family businesses have been found to outperform similar non-family businesses (Anderson & Reeb, 2003a), this performance advantage does not appear to directly translate into long-run survival, as less than 10 % of family businesses survive through the third generation (Kets de Vries, 1993).

Various arguments have been proposed to explain the low survival rate of family businesses, including increased conflict among later generation of family members (Davis & Harveston, 1999), and incompetent heirs (Morck & Yeung, 2003; Shleifer & Vishny, 1997). Some researchers argue that a lack of commitment among current and/or later generations of family members may also affect survival (Aronoff, 2004; Chua, Chrisman and Steier, 2003). However, the lack of research on commitment in the context of family business has led to a gap in our understanding of what triggers commitment among family members towards continuing the family business. We define family's commitment to business, here after referred to as family commitment, as the desire of family to preserve and continue the business as a family business (e.g. Davis, Allen, Lahiri, & Mahto, 2004).

Recently, Davis et al. (2004) examined the extent to which commitment varied across family firms based on a variety of factors including social interactions (e.g., family and

shareholder meetings), financial dependency (e.g., the amount of the family's net worth tied up in business), family control of the top management team (TMT), and dispersion of family ownership (e.g., the number of family owners). However, in this paper we argue that identification with the family business mediates the relationship between commitment and its previously proposed antecedents. We draw upon the commitment literature (e.g. Meyer & Allen, 1997) and social identity theory (e.g. Ashforth & Mael, 1989) to link identification with business and identity with family commitment. We use the upper echelon perspective (e.g. Hambrick & Mason, 1984), psychological ownership (e.g. Pierce, Kostova, & Dirks, 2001), and organizational commitment (Porter, Steers, Mowday, & Boulian, 1974) to link family representation in the TMT, the number of owners, meetings (family and shareholders), and investment to identity and family commitment.

The defining characteristic of family business is the involvement of family members in the business (Chua et al., 2003). Family members generally have a large stake in the business providing them substantial control and influence over the firm's behavior. As a consequence of this, roles from two distinct domains, family and business, spillover in each other (Chrisman, Chua, & Litz, 2003) thereby closely linking the family with the firm. We argue that in such family-owned businesses, the impact of the CEO's ties to the founding family extends beyond the purely economic. CEO family ties should have an impact on the psychological bonds that link family members to their family business. Prior research suggests that a leader's (e.g., the CEO) ties to the family have a substantial impact on business outcomes (e.g. Anderson & Reeb, 2003a; Morck, Shleifer, & Vishny, 1988; Schulze, Lubatkin, Dino, & Buchholtz, 2001). Unfortunately, prior research does not guide us on the question, "Does the CEO's relationship with the founding family affect the

development of family commitment?” In this study, we propose that the presence or absence of CEO ties to the founding family will act to moderate relationships in our proposed model.

The progression of the rest of the paper is as follows. We start with a brief review of family businesses. In the next section, we present our model and offer an explanation of the CEO’s influence on the relationships proposed in our model. We then provide a description of our data, methods, and analysis. The paper ends with a presentation and discussion of results and suggestions for future research.

## **FAMILY BUSINESS**

The complexity of family entanglement with the business has led to the lack of a precise definition for family business (Dupuis, 1994). However, researchers are unanimous in their view that the founding family has substantial influence and control in family businesses (Morck & Yeung, 2003). Thus, researchers in the different disciplines of finance, management, marketing, and strategy have used the involvement of the founding family to categorize organizations into family and non-family business (e.g. Morck, Strangeland, & Yeung, 2000; Anderson & Reeb, 2003a; Anderson & Reeb, 2003b; Anderson, Mansi, & Reeb, 2003). By family, we mean “a group of people related by blood, adoption, or marriage” (e.g. Edwards & Rothbard, 2000). In effect, the role the family plays is crucial in distinguishing family firms from non-family firms.

Family firms are ubiquitous in the U.S. economy; with estimates suggesting that family businesses comprise an estimated 65 % to 85 % of all businesses (Gersick, Davis, Hampton, & Lansberg 1997), employ over 85 % of the labor force (Gomez-Mejia, Larrazakintana, & Makri, 2003), and contribute over 50 % of gross domestic product (McCann, Leon-Guerrero, & Haley, 1997). Despite their overwhelming presence in the economy, their

representation in academic research has been lacking (Dyer, 2003; Schulze et al., 2001), resulting in a critical gap in our understanding of this critical component of the U.S. economy.

Of the many complex problem and dilemmas faced by family business, the survival of the family business is paramount. Yet, the statistics suggest that less than 30% of businesses survive beyond the life of their founders (Kets de Vries, 1993). Related to survival is the problem of ensuring the involvement and commitment of family members in the business. Commitment is viewed as a necessary condition for the continuous involvement of family members, independent of potential profit expectation from the business (Astrachan, 2003).

### **MODEL DEVELOPMENT**

The concept of commitment has captured the attention of organizational researchers for many years (Hom & Griffith, 1995). Organizational commitment, defined as an individual's involvement, identification, and attachment with the organization (e.g. Allen & Meyer, 1990), has been found to influence organizationally valued outcomes such as turnover (Hom & Griffith, 1995) and performance (Somers, 1993). Researchers have generally agreed that commitment has three forms (i.e. affective, normative, and continuance) which generally affect organizations at both organizational and individual levels and produce different outcomes (e.g. Meyer & Allen, 1997; Somers, 1993). Family commitment as presented here is a group level (i.e. family) construct and is different from the three forms of organizational commitment. Despite having common roots with notions of organizational commitment (for reviews of the organizational commitment see Mathieu &

Zajac, 1990; Meyer & Allen, 1997), the literature does not provide much guidance regarding the drivers of commitment in family businesses.

In the family business, founding families are expected to exhibit varying levels of commitment towards maintaining family ownership and control of the business. The development of family commitment may be crucial to intergenerational succession in family businesses. However, the limited research in family commitment does not provide a clear direction. It is tempting to propose that mere ownership creates commitment among family members following the intrinsic model of employee stock ownership plan (ESOP) literature (e.g. Klein, 1987), which argues that ownership alone is sufficient to create commitment. However, it may be dangerous to apply this concept directly given the vastly different context and level of analysis. According to psychological ownership theory (Pierce et al., 2001), the symbiotic relationship between the family and the business, in which there is significant overlap in family and business subsystems (Chua et al, 2003), may create identification among family members. Identification may be antecedent to the development of family commitment, warranting a closer examination of this relationship.

*Identity-Commitment Relationship.* Work in the commitment research suggests that identification is a distinct construct and not a dimension of commitment (e.g. Mael & Tetrick, 1992). Tannenbaum (1983) in his work on ESOP proposed that identification is the key to understanding changes in employee attitudes like commitment. Since then, a stream of research has continued to suggest that identity produces positive attitudinal changes in individuals, such as higher commitment (Ashforth & Kreiner, 1999; Ashforth & Mael, 1989; Foreman & Whetten, 2002; Whetten, Lewis, & Mischel, 1992). Ashforth and Mael defined “social identification as the perception of oneness with or belongingness to some human

aggregate” (1989: 21). The close involvement of the family in the business makes it normal for the family role to spillover into the business and vice versa, implying that family members’ perceptions of self could be based on their affiliation with their family business. To some extent, family members’ self-esteem may be related to the continuance of the family business (Brown, 1997; Elsbach & Kramer, 1996). As the family members’ identity links the reputation of the family with business survival (Anderson et al., 2003) any threat to the business’s reputation will appear as a threat to individual’s identity. Once the family members’ reputations are linked with the business, a threat to the business’s survival becomes a threat to the existence of the family itself (Kets de Vries, 1993).

Stronger family identification with the business is also reinforced by the association of the family’s name with the business. It is quite common that the family name (e.g. last name) is shared by the business (Kets de Vries, 1993), thereby visibly linking the family to the business in the external environment. Over time the linkage becomes so strong that people outside the business fail to differentiate between “the family” and “the business”. This construed external image (Dutton & Dukerich, 1991) not only creates a strong cognitive connection between the family and the business in individuals outside the family but also creates a similar cognitive effect in family members. In constructing a particular organizational identity for presentation to outsiders, family members reinforce the inseparable part of family and business.

This higher identification or the perception of “oneness” with the business (Ashforth & Mael, 1989) encourages family members to maintain the business in family ensuring the legacy for future generations (Anderson et al., 2003). Thus, the commitment to preserve the family business will be higher. The expectation that identification with the family business

will affect family members' commitment to continue their family business provided the basis for the first hypothesis.

Hypothesis 1: *Family identification with the business will positively impact family commitment.*

*Family involvement and Identity Relationship.* Family members' common genetic origin provides them a sense of shared common identity. The family business is often the primary, even the sole source of the livelihood and wealth for family members. Because their fortune is associated with the business, family members meet to discuss future business directions and plans (Habbershon & Astrachan, 1997). During these family meetings, family members often discuss their common history and heritage, beliefs and values, thus reinforcing feelings of shared identity and increasing the potential for collective action (Habbershon & Astrachan, 1997).

Ownership among the family members reinforces the feelings of shared identity among them (Gomez-Mejia et al., 2001) as well as ensuring that family members share in the pecuniary advantages related to business ownership. Because of this direct linkage between their wealth and the business, the family's perceived identification with the business increases as their net worth invested in the business and their meetings (family and shareholder) increase.

A defining characteristic of family businesses is that family members are involved in the business and they assume various roles at different levels of the organizational hierarchy. In most cases, the family is represented in the organizational decision-making by the virtue of their participation in the top management team (TMT). Top managers have a special role for other family members because they are representatives of the other family members. The more family members assume responsibility for the management of the business, the more

their decisions and actions will affect the welfare of the family business. Having family members in the top management team reinforces to the family owners that they own and control their family business. It is likely that family members' identification with their family business would be enhanced by their participation in the top management of the firm. The above discussion leads to our second hypothesis.

Hypothesis 2: *Family investment, participation in the top management team, and family and shareholder meetings will positively influence the extent of family identification with the business.*

Previous research suggested that family investment, participation in the TMT, and family meetings are all positively correlated with family commitment (Davis et al., 2004). As shown in Figure 1, we propose that the family members' identification with the business mediates the relationship between the family social interaction and investment variables. Greater participation by the family in top management, more frequent family and shareholder meetings and greater financial dependence on the family business lead to increased identification with the business by family members. This increased identification, in turn, will increase the commitment of the family to continue the business as a family business. Consistent with prior research and with our two previous hypotheses, we propose following hypothesis.

Hypothesis 3: *Family identification with the business mediates the relationship between family variables (family investment, participation in top management team, and meetings) and family commitment.*

-----  
Insert Figure 1 about here  
-----

*CEO Family Ties.* One common theme in family business research is the influence exerted by the CEO or top leadership on the firms' behavior and performance (Morck & Yeung, 2003; Anderson & Reeb, 2003a). In particular, much of the literature in this area has focused on the CEO's ties to the family as affecting organizational outcomes. Anderson & Reeb (2003a) argued that while the founding CEO is good for business performance, successors and non-family CEOs are not good for business performance. Morck and Yeung (2003) indicated that the CEO's ties to the family influences the risk assumed by family business, while Anderson and Reeb (2003b) suggested that CEO ties to family influence the cost of the debt financing. Shleifer and Vishny (1997) argued that non-family CEOs can cause dissatisfaction and feelings of alienation among family members. Thus, the CEO's ties to family can have a critical impact on the family business. However, the literature in family business does not provide clear guidance regarding the impact of a CEO's family ties on the relationships investigated in this study. Although theory and evidence are meager we offer the following arguments regarding the impact of the CEO's family ties on organizational identity and commitment.

Having reached the apex of the organization, the CEO is not just an average manager. According to Gioia and Chittipeddi "the CEO is typically portrayed as someone who has primary responsibility for setting strategic directions and plans for the organization, as well as responsibility for guiding actions that will realize those plans" (1991: 434). Therefore, the CEO has the major responsibility for the strategic success of the firm (Vance, 1983). In addition, the CEO influences employees' identification with the organization; furthermore, the CEO represents that organization when dealing with external organizational constituents (Norburn, 1989). The pervasiveness of the CEO's influence implies that family ties should

have an impact on the development of identity and commitment among employees (i.e. family members).

Family psychologists have suggested that family members are generally more attached to their closest genetic relatives such as mother, father, brothers, and sisters than more distant relatives such as a brother/sister in-law. When the CEO is also a member of the founding family, other family members may have a stronger psychological sense of ownership of family business causing a subsequent increase in their identity and commitment. Conversely, when a family firm hires a non-family member CEO, it begins to resemble a non-family business as it separates the family from the governance of the business. A non-family member occupying the most critical position in the family business might signal to both outsiders and family members that the family no longer desires to control the business. The lack of close familial ties at the apex of the organization may attenuate family members' emotional and psychological attachment or ownership. Hence, the level of identity and commitment among family members will vary depending on the CEO's relationship to the founding family.

Alternatively, it may be that the CEO family ties will not moderate the relationship. In order to survive in the competitive environment, hiring a competent CEO may be considered an inevitable step in firm survival. This could be necessary if the family does not have a qualified candidate. Indeed, the hiring of a non-family CEO to lead the firm may be the decision of family members most interested in continuing the legacy. Although there are competing arguments, we offer the following hypothesis for testing.

Hypothesis 4: *CEO ties to the founding family moderates the relationship between (1) family variables and identification with business, and (2) identification with business and family commitment.*

*Control Variables.* As the family size increases, the potential for conflict among family and the dispersion of business ownership increases (e.g. Davis & Harveston, 2001). This may affect family cohesion and the ability to take collective action (e.g. Habbershon & Astrachan, 1997). The lack of cohesion and unity in the family may have detrimental consequences on the family's identification with the business and family commitment. In order to remove the potentially biasing effect of ownership dispersion in the family, we controlled for the influence of the number of adult family owners on identification with the business and family commitment.

*Summary.* As shown in Figure 2, we propose that social factors, such as family representatives in the top management team, family and shareholder meetings, and the percentage of the family's net worth invested in the business, will determine perceived identification with the business, which, in turn, affects family members' commitment to continue the family business. We further propose that these relationships are influenced by the CEO's ties to the founding family.

## **METHOD**

Two different sets of family business data were used to test the hypotheses proposed in this paper. The first data set was obtained from a national survey of family businesses conducted by the Arthur Andersen Center for Family Business with the assistance of the Loyola University of Chicago's Family Business Center and the Family Enterprise Center at the Kennesaw State University in 1997. The second data set was obtained from similar survey of family businesses conducted in 2002 by almost the same group of organizations

except the George & Robin Raymond Family Business Institute and Babson College replaced the Arthur Andersen Center for Family Business. In both data sets, the sample of potential businesses was randomly drawn from a comprehensive, nationwide database of family-owned businesses maintained by Dun & Bradstreet.

To be included in either of the surveys, all firms had to meet the following criteria: the company had at least ten employees; the company had annual revenues of at least two million dollars; the company had been founded at least ten years prior to the survey; and the company had to self-identify the business as a family business.

The first data set (1997 survey) initially contained 3033 observations. After removing incomplete surveys, we obtained a final usable sample of 2154 family firms. In order to test the moderation effects of CEO family ties, we divided the first sample into three different sub-samples based on the CEO's relationship (ties) with the founding family. The first sub-sample contained 1891 family businesses led by CEOs who were related to founding family by blood or adoption (RB sample). The second sub-sample contained 152 family businesses led by CEOs who were related to founding families by marriage (RM sample), and finally, the third sub-sample contained 111 family businesses headed by non-family CEOs (NR sample). We used the RB sample for model refinement purposes.

Therefore, we divided this sample randomly into two different sub-samples with 945 observations each. We named the first sub-sample, used for testing the proposed model presented in Figure 1 (without moderation effects), the *calibration sub-sample*. The second sub-sample, used for testing the refined model, was named the *validation sub-sample*.

The second data set (2002 survey) initially contained 1143 observations but it did not have enough observations for family businesses led by CEOs related to the family by

marriage or non-family CEOs. We used the second data set to establish the convergent and discriminant validity of our commitment scale measures and the organizational commitment scale (OCQ) measures developed by Porter, et al. (1974). A listwise deletion for missing observations provided us a final usable sample of 845 family businesses.

## MEASURES

*Family Variables.* We used four different indicators of family participation in the business: family meetings (FMEET), shareholder meetings (SMEET), family members in the TMT (FAMTMT), and family investment in the business (NETWORTH). Family meetings was measured by asking respondents, “How many formal family meetings (other than shareholder meetings) are held each year?” Respondents indicated their preference on four available options: 0, 1-2, 3-4, and 5 or more. These same options were used to measure shareholder meetings. The respondents were asked to provide number of shareholder meeting held each year by asking, “How many shareholder meetings are held each year?” Respondents indicated the number of family members in the TMT of the family business in response to the question, “How many family members are on the company’s top management team?” Finally, the family’s extent of financial involvement or investment in the business was operationalized by asking respondent to indicate, “Approximately what percentage of the family’s net worth is tied up in the business?” Answers were provided using a quintile scale, where 1 indicated less 20% and 5 indicated greater than 80%.

*Family identification with business.* In order to measure the family’s identification with the business respondents were asked, “How much does the business contribute to the family’s identity in the community and elsewhere?” They indicated their preference on a 5-point Likert-type scale ranging from 1 = Not at all to 5 = Very much so. The use of a global

measure of identity for this study allowed us to capture an overall assessment without focusing on other dimensions of identity (e.g. Dutton et al., 1994; Goldberg, Riordan, & Schaffer, 2004).

*Family Commitment.* Many measures have been proposed to assess commitment (see Reichers, 1985; Van Dick, 2001) however, their applicability for our purposes was questionable. Two arguments in particular swayed us from prior measures. First, unlike most previous studies that largely assumed the relationship between the employee and the firm to be of a strictly contractual nature, we specify the presence of a familial relationship. Hence, our sampling frame is restricted to family businesses. Secondly, the unit of analysis is different. Most previous measures of the notion of continuance commitment addressed an individual's intent to remain with the firm. Here, we assess family commitment as a group-level psychological construct, rather than an individual level construct. These differences are reflected in the items and composite scale used to tap the domain of family commitment.

To represent family members' attitudes towards the continuance of the family business, herein referred to as COMMIT, we constructed a composite measure that consisted of two items. The first item tapped the expressed level of commitment among the senior generation towards continuing the family business, while the second item tapped the level of commitment perceived to exist among the next generation of family members. Both items measured the extent of commitment present using a five-point Likert-type scale from 1 = not at all to 5 = very much. To capture the combined level of commitment across generations, responses on the two items were summed.

*Organizational Commitment Questionnaire (OCQ).* An eight-item version of the Organizational Commitment Questionnaire (OCQ) scale developed by Porter et al. (1974),

was adapted to the family business context in the second sample. One sample question from this scale is, “As family, we support the family business in discussions with friends, employees, and other family members.” The respondents indicated their agreement with items of the scale on a five-point Likert-type scale that ranged from 1 = Strongly Disagree to 5 = Strongly Agree.

*Control Variables.* To operationalize our control variable, ownership dispersion (OWNER), respondents were asked to indicate the number of adult family owners.

### **ANALYSES AND ASSESSMENT OF MEASURES**

*Analysis.* Initially we used exploratory maximum likelihood factor analysis for establishing the convergence and discriminant properties of our family commitment scales measures versus organizational commitment (OCQ) scale measures developed by Porter et al. (1974) in the second data set. Later, we used structural equation modeling using LISREL 8.51 (Joreskog & Sorbom, 1993) for conducting confirmatory factor analysis, model generation, and assessing the stability of the final model. We used the sample covariance matrix as input for LISREL 8.51 and fixed measurement loading (square root of the scale reliability times standard deviation) and error variances (one minus reliability times the scale variance) (Bollen, 1989; Joreskog & Sorbom, 1983) in the *initial* and *revised* model. Following Donovan, Brown, & Mowen (2004), single item measures were assumed to have a reliability of .85 while testing the *initial* and the *revised models*. We first evaluated the fit of the initial model with the *calibration sub-sample* to arrive at the revised model. While assessing the fit of the model with the data, we examined chi-square statistics as well as the root-mean-square-error of approximation (RMSEA), standardized root-mean-square-residuals (RMR), the goodness of fit index (GFI), the adjusted goodness of fit index (AGFI)

(Joreskog & Sorbom, 1984), the normed fit index (NFI) (Bentler & Bonett, 1980), and the comparative fit index (CFI) (Bentler, 1980; Hu & Bentler, 1999). As chi-square is sensitive to sample size (Cudeck & Henly, 1991), it was necessary to examine other measures of fit to interpret the fit of the model with the data.

*Assessment of Measures.* Initially we conducted exploratory maximum likelihood factor analysis with ten items in the second data set (2002). These items included the eight-item organizational commitment scale (OCQ) (Cronbach's alpha,  $\alpha = .90$ ) and the two-item family commitment scale (COMMIT) (Cronbach's alpha,  $\alpha = .80$ ). As these constructs should be related, we examined solutions with oblique rotation. The results of this analysis supported our *a priori* two-factor solution and provided us two factors with eigenvalues greater than one. The resulting two-factor solution accounted for 64% of the variance in the sample. Consistent with our expectations, the two indicators of family commitment (COMMIT) and the eight indicators of OCQ loaded heavily on appropriate factors while the cross loadings were weak.

Later, we conducted confirmatory factor analysis using LISREL 8.51 (Joreskog & Sorbom, 1993) with the same ten items comprising the two scales (COMMIT & OCQ). The obtained fit statistics, with the exception of chi-square, suggested a moderate fit of the measurement model with the data ( $\chi^2_{34} = 327.01$ ;  $p < .05$ ; RMSEA = .094; RMR = .032; GFI = .94; AGFI = .92; NFI = .93; NNFI = .92; CFI = .94; Hu & Bentler, 1999; Bollen, 1990). Given the large size of the sample ( $n = 845$ ), the significance of chi-square is not surprising (e.g. Cudeck & Henly, 1991). However, the other measures indicated a moderate fit of the measurement model with the data. We also assessed the significance of each path in the measurement model by examining the associated t-value of the path. A t-value  $> 1.96$

indicates significance of the path at  $p < .05$ . The results of confirmatory factor analysis suggested that all paths were significant. The average variance extracted (AVE) for OCQ and COMMIT scale items were .54 & .65, respectively. This suggested that the measures of the two items satisfied the most constrained test of convergence validity established by Fornell and Larcker (1981). The shared variance between the two constructs was only .07, which was much lower than the AVE of measures of two constructs. This indicated that our measures exceeded the discriminant validity criteria established by Fornell and Larcker (1981). Discriminant validity was also established by imposing a single factor solution in the measurement model. The single factor solution deteriorated the model fit significantly as indicated by a significant increase in chi-square ( $\chi^2_1 = 399.56$ )<sup>1</sup>(see Anderson & Gerbing, 1988).

*Model Evaluation & Revision.* The proposed *initial model* without moderation, presented in Figure 1, was tested on the *calibration sub-sample*. The fit indices ( $\chi^2_4 = 37.86$ ,  $P < .05$ ; RMSEA = .092; RMR = .037; GFI = .99; AGFI = .93; NFI = .89; NNFI = .70; CFI = .90) indicated a moderate level of fit. With the exception of the SMEET  $\rightarrow$  COMMIT path, all paths included in the model were significant ( $t$ -value  $> 2.0$ ). The modification indices suggested the addition of a path from family TMT to family commitment (COMMIT). In the *revised model*, we added a path from FAMTMT  $\rightarrow$  COMMIT. This *revised model* was again tested on the *calibration sub-sample*. The fit indices ( $\chi^2_3 = 5.29$ ,  $P > .10$ ; RMSEA = .028; RMR = .01; GFI = 1.00; AGFI = .99; NFI = .99; NNFI = .95 CFI = .99) suggested an excellent fit between the *revised model* and the *calibration sub-sample*. Again all hypothesized paths with the exception of SMEET  $\rightarrow$  COMMIT were significant. Next, we tested the *revised model* on the *validation sub-sample*. The fit statistics ( $\chi^2_3 = 5.96$ ,  $P > .10$ ;

---

<sup>1</sup> An increase of 3.84 in  $\chi^2$  for 1 df indicates the significant change in the model at the .05 level.

RMSEA = .032; RMR = .01; GFI = 1.00; AGFI = .98; NFI = .98; NNFI = .94 CFI = .99) suggested good fit of the *revised model* with the *validation sub-sample*. The fit statistics along with completely standardized path estimates for the initial and the *revised model* can be found in Table 1. We also examined the indirect paths in the model which are presented in Table 2.

-----

In order to test the moderation effect of CEO ties to the founding family on the relationships proposed in this study, we conducted simultaneous three group (RB, RM, & NR samples) analysis using LISREL 8.51 (Joreskog & Sorbom, 1993). We started with the most constrained three-group analysis. This model, in which all parameters were constrained to be equal across three groups, was used as the *base model* for testing the moderation effects. Although the chi-square statistic for the *base model* was significant ( $\chi^2_{29} = 49.62, P < .05$ ) the ratio of chi-square to the degrees of freedom was less than 3, indicating a good fit of the model with the data (e.g. Hughes, Price, & Marrs, 1986). The other fit statistics also indicated a moderate level of fit. The standardized path estimates along with fit statistics for three-group analysis can be obtained in Table 3. In order to test for moderation effects, we freed one path across two groups at a time in the *base model*, and examined the chi-square difference between the base model and the resulting less-constrained model. If the chi-square difference was significant, then the CEO's ties to the family moderates the freed path across the two groups. We repeated the chi-square difference test for all possible hypothesized paths two groups at a time. The summary of these results can be found in Table 4.

## RESULTS

The means, standard deviation, and correlation among study variables from the first data set (1997 survey) are presented in Table 5. As shown in Table 5, IDENTITY is significantly correlated with all four family variables (SMEET, FMEET, FAMTMT, & NETWORTH). Family commitment is positively and significantly related to family identification with the business and three of the family variables (SMEET, FMEET, & FAMTMT). In general, the correlations among the study variables do not rise to a level evidencing multicollinearity.

-----  
Insert Table 5 about here  
-----

The first hypothesis (H1) suggested a positive influence of identification with the business (IDENTITY) on family commitment (COMMIT). As can be observed in Table 1, IDENTITY has positive and significant ( $\beta = .27, .27$ ;  $t$ -value = 7.06, 7.18) impact on family commitment (COMMIT) in both the *calibration* and *validation sub-samples*. Even in the base model (Table 3), IDENTITY has a significant ( $\beta = .24$ ;  $t$ -value = 11.70) influence on family commitment. This indicates that the hypothesis H1 is strongly supported.

For the second hypothesis, we were expecting positive influences for the four family variables (SMEET, FMEET, FAMTMT, & NETWORTH) on family identification with business (IDENTITY). In both the *calibration* and *validation* sub samples, family meetings ( $\beta = .13, .18$ ;  $t$ -value = 3.22, 4.17) had a significant positive impact on IDENTITY. Family

TMT ( $\beta = .11, .16$ ; t-value = 2.77, 3.67) and NETWORTH ( $\beta = .12, .08$ ; t-value = 3.34, 2.03) also positively influenced the family's identification with the business. The significant positive impact of these three family variables (FMEET, FAMTMT, & NETWORTH) was also supported in the base model (Table 3). Shareholder meetings, although it had a positive influence on IDENTITY, its impact was not significant. In general, the results provide some support for hypothesis H2.

The third hypothesis (H3) suggested that IDENTITY mediates the relationship between family variables and family commitment. As can be observed in Table 2, family meeting ( $\beta = .04, .05$ ; t-value = 2.93, 3.60), representation in TMT ( $\beta = .03, .04$ ; t-value = 2.61, 3.33), and investment in the business ( $\beta = .03, .02$ ; t-value = 3.02, 1.96) had significant indirect effects on family commitment through IDENTITY. However, shareholder meetings did not have a significant indirect impact on family commitment. The majority of the indirect paths were significant, indicating support for hypothesis H3.

Hypothesis H4 proposed that CEO ties to the founding family would moderate the relationships investigated here, as shown in Figure 2. As can be seen in Table 4, CEO ties to the family moderated only the IDENTITY  $\rightarrow$  COMMIT path. It had no significant impact on other paths in the model. On balance, the preponderance of evidence suggests that the presence or absence of ties between the CEO and the founding family does not moderate the majority of relationships of interest here, thus we reject H4.

## **DISCUSSION AND CONCLUSION**

The primary objectives of this study were to investigate the link between identity and family commitment, and the impact of CEO ties to the founding family on revealed

relationships. We did this by focusing on identity as the antecedent to commitment and by treating the ties between the CEO and the founding family as a moderating variable.

Our results support the proposition that the family's identification with the family business affects their commitment to preserve the family business. Family meetings (number of family meetings), the degree of family involvement in the management of the firm (i.e., as members of the TMT) and the family's financial dependency on the business (i.e., the percentage of family net worth tied up in the business) were shown to have a positive influence on the development of the family's identification with the business. Unexpectedly, shareholder meetings were not a significant predictor of family identification (IDENTITY) with the business. Perhaps, shareholder meetings are not an antecedent of identity because they tend to be limited to discussions about business operations and future plans, which might increase the potential for conflict due to diversity in equity, opinions, and competing claims over business gains. In contrast, family meetings increase identification because business discussions are secondary to family issues (Habbershon & Astrachan, 1997). Discussion of family issues may reduce the appearance of conflict among family members and create conditions for collective action. Our study also provides support for the mediating effects of identity on the relationship between family variables and family commitment. All but one of the family variables (i.e., shareholder meetings) were shown to have a significant indirect impact on family commitment through identity.

The results also suggest that certain antecedents of identity are more important than others. Among the variables investigated here, the number of family meetings was the most important in determining family members' identification with the family business. This finding suggests that social interactions are essential to furthering identification among

family members. Researchers consider identity as a social construction (Gergen & Davis, 1985) as it is derived from repeated interaction with others. As suggested by Pierce et al. (2001), in the context of family business, communication and discussion of business and family issues among family members allows the group (family) to develop a sense of ownership toward the business. In effect, social interaction installs a strong feeling of “our” or “my” and reduces the tendency of “they” or “their” among family members. In addition, the active participation of the family in the management of the firm (e.g., as members of the TMT) significantly affected both identity and commitment. This finding was consistent with theories of psychological ownership, in that increased family representation in the business increased the family’s perceived influence and control over the business, providing a basis for the development of identification.

While the results of tests of moderation between the antecedent variables and identity were negative, there was some evidence that the presence or absence of particular forms of familial ties between the CEO and the founding family served to moderate the relationship between identity and commitment. The relationship between identity and commitment was stronger when the CEO was related by blood to the founding family or was a not a family member. There was no difference between these two groups. In contrast, lower family commitment was evident among firms that were led by a CEO who was related by marriage to the founding family. This is an interesting finding for understanding the impact of family ties on family commitment. Perhaps, the presence of a blood relationship between the founding family and the CEO (a family member) precipitates a common bond and a set of mutual expectations derived from common family experiences, values, emotions and sentiments than is possible when the CEO is related by marriage. Also, when the family

business hires a non-family CEO, the implication is that family members may not possess the required skills and expertise to successfully manage the business. In order to preserve their family business, family members may consider it is necessary to hire non-family member with the needed qualifications and/or credentials for the business to survive.

In contrast, when the CEO's relationship is based solely on marriage to a founding family member, they do not possess a familial bond or historic relationship with other family members. Divorce is a common phenomenon in the U.S., over 50% of marriages in the U.S. end in divorce (Braver & O'Connell, 1998; Sheets and Braver, 1996). As a result, family members' relationships with the CEO may not be viewed as stable, leading to some attenuation of commitment among members of the founding family.

We extended theory by assessing commitment among family business owners. In doing so, we went beyond most previous investigations that were limited to studies of commitment among employees/owners. In addition, our study supports extending the treatment of commitment beyond a merely individual level phenomenon, to considering it as existing at the group-level (i.e., family) as well. In the family business context, we also demonstrated the importance of including identity when examining family commitment.

Our findings suggest that when examining the role of family ties in organizational relationships, we should recognize the complex nature of the family. Previous research on family ties has examined the difference between family and non-family leadership (Anderson and Reeb, 2003a; Gomez-Mejia, et al., 2001) our findings suggest that within the family the nature of the relationship (related by blood vs. related by marriage) may play an important role.

The results of this study need to be evaluated through additional research. The samples used here were cross-sectional and the family variables were reported by an individual respondent representing the family. However, we attempted to address the measurement issue by including the probability of error in our measures. Despite these limitations, the results provide a clearer picture than was previously available of the conditions that affect the complex relationship between family ties and organizational outcomes.

# How Well SMEs Cope With Risk Management Issues: A Study In Singapore Context

By: MBA Dissertation Team comprising:

Anthony Mak

Calvin Foo

Richard Ong

Thomas Mathew

Supervised by BC Ghosh, Dean( Vancouver University, Canada's Singapore Operations), and Tan Wee Liang, (Singapore Management University).

## An Abstract

Unmanaged business risk is the bane of businesses. We studied through an interview process the risk management processes of 61 organizations ie small/medium size businesses in Singapore and evidence showed that they( esp those in medium category) were adequately conscious of financial and operations risk management needs. Whilst that were re-assuring, the Tsunami in Asia starkly showed the unprepared-ness of small businesses to survive against business shocks. That happened after the paper was written and will probably be subject matter of yet another paper.

## Introduction

In all national economies, the majority of the business set-ups are Small and Medium Enterprises (SMEs). In the United States, of the 19 million businesses in the country, almost 97% of these are in the small business sector and many expect this sector to grow in view of the new economy fuelled by technological breakthroughs and downsizing of large corporations. Currently, about 99% of all businesses employ fewer than 100 workers.

SMEs are defined differently from one country to another. In the US, a small business has less than US\$20 million in annual sales and employs fewer than 500 workers. In the UK, government statistics focus on companies employing less than 200. Hong Kong limits the number of workers to less than 100 for manufacturing and less than 50 for non-manufacturing concerns.

In Singapore, an SME is one with minimum 30% local ownership that employs less than 100 in a service sector and for those in the manufacturing sector, fixed assets of less than \$12 million( a kind of Government accepted definition for all SME related assistance purposes). For our studies, we define an SME as one hiring less than 200, regardless of the percentage of foreign ownership. **The reason is: we wanted to identify small firms, but not micro-firms for our purposes, with whose senior enough officers we could**

**meaningfully discuss the issues of risk-management. These firms in a Singapore context hence are mid-size. And our interviews will be structured, but face to face, again to be meaningful and data meaningfully derived.**

Entrepreneurship is a dynamic process, which requires certain qualities and skills, and we assumed as variously identified in literature that entrepreneurship capacities/ qualities, are not necessarily innate. An awareness and knowing the ways to deal with risk will represent a fundamental factor that would speed up the transition to a successful business. Risk is extremely prevalent in a highly competitive economy such as Singapore is.

The focus of this study is on Singapore's SMEs' approach and their awareness level of risk management. We attempt to illustrate its characteristics and how SMEs manage risks with special regard to the operational and financial aspects of businesses.

### **Definition of Risk**

Risk is a condition in which there is a possibility of an exposure to adversity. There is a chance deviation from the desired outcome that is expected or hoped for. Risk has become an integral part of our personal and business life. It spans from the level of personal safety, health, accident and employment to corporate asset depreciation, production, inflation, foreign exchange rates, etc. Risk is an essential element in business, every time that a decision is made regarding an investment, the purchase of goods or services, spending marketing dollar on promotions, launching a new product etc, risks exist.

Companies have traditionally viewed risk as the potential occurrence of loss or failure. This is too narrow in scope and a tad too negative in perspective as risk could also represent the opportunity to take profits. Just as organizations need to take preventive steps to avoid or mitigate potential losses (hazard risk), they must take actions to achieve positive gains (opportunity risk). Meanwhile, unknown events are always acknowledged to be ever-present (uncertainty risk).

**A risk situation occurs when you are required to make a choice between two or more alternatives whose potential outcomes are uncertain and must be subjectively evaluated. A risk situation involves potential success and potential loss. The greater the possible loss or profit, the greater the risk involved.**

The Practice of Entrepreneurship, ILO, 1996, Geneva

Risk situations are characterized by the presence of uncertain events. **Uncertainty** exists when the probability of outcomes has to be subjectively assigned since there is not enough historical data to fully depend on. Common reasons for uncertainty are inflation impact on businesses, changes in technology, productivity and prices, consumers' demand, political, social, and business environment changes. Risks can also arise due to natural reasons ie draught, flood, earthquake or similar. Most of these risks are insurable; but risks arising from economic reasons, social upheavals and across the world events(

now that the world is becoming a global village) are the ones to which our businesses need to be more alert and responsive.

Risk should be assessed, warded and managed through proper **analysis and planning**. Speculative risk can be used in business, but it is important that entrepreneurs properly plan and monitor their use. Good managers try to reduce speculative risk through careful study and planning, putting in place measures to manage and hedge the inherent risks. They are always mindful that a successful speculative operation might bring large profits, but this poses danger for the company as speculation could bring about potential losses too if proper risk management is not in place. Risk awareness reduces but certainly not eliminates this possibility.

### **The Importance of Risk Management for SMEs**

Risk Management is a scientific approach to the problem of pure risk, and its objective is the reduction and elimination of pure risks facing the company. The field of risk management has evolved steadily from corporate insurance procurement and most recently been recognised as a distinct and important function for all businesses.

**Risk management contribute to the organisation's general goals in many ways.** A good example is having a fire insurance policy in place in case a fire may break out to destroy a factory. By ensuring the organisation's survival is enough to justify the existence of risk management practices in place. But risks can be much more complex than this, and complexity requires complex management.

**Risk should be viewed as a challenge and not an obstacle.** Growth and renewal is only possible for the entrepreneur and the organisation if there is a healthy approach to risk-taking and managing the business. With relative limited resources like financial and manpower, it is imperative that decision must be made as to how best risks are managed.

**Entrepreneurship requires a risk-taking culture and risk is an integral part of business' activities.** Security should therefore be more completely defined under the headings of assurance, integrity and availability. Rather than being a state of total peace of mind, security should mean risks have been reduced to an acceptable level.

**In business, as in life, there is clearly no way to avoid risk-taking. When you take risks, you discover your own abilities and you will become better able to control your own future will become more self-assured. You will have a more positive outlook towards risk-taking because you have faith in your own abilities. You will accept risks as challenges that require your best efforts to achieve goals.**

The Practice of Entrepreneurship, ILO, 1996, Geneva

## **2 Scope of our research**

In this study, we researched mainly the importance and significance of operational and financial risk in Small and Medium Enterprises (SMEs) in Singapore. The four forms of businesses surveyed were sole proprietor, partnership, private limited and public listed companies.

In an APEC Survey on Small and Medium Enterprises 1994, they defined SMEs used within Government departments in terms of “number of employees”, “turnover” or “accounting based”. The APEC survey went on further to define SMEs as all the enterprises employing fewer than 100 people, including the self-employed. In our scope of this study, we defined an SME as one having less than 200 workers for reasons earlier explained..

Operational and financial risk management is important, as a string of large and highly public corporate failures over the past 10 to 15 years has focused investors and regulators attention worldwide on the way in which companies are managing their risk. We are living in a connected world where events like 9-11, SARS, bird flu, Iraq war, Asian Financial Crisis have affected how we do business and the way we live. In Singapore, the bulk of the impact was borne by the small men, as probably elsewhere, or small businesses.

Many companies have focused on value creation as a key goal. But without adequate procedures in place to manage risk, many are unable to create a real sustainable value. Therefore operational and financial risk management is now a core business process and should be planned accordingly so as to reduce risk and volatility and improve returns.

Larger enterprises have generally accepted the strategic importance of effective risk management and set up risk management functions. *SMEs have lagged behind, partly due to the economic resources and cost/benefit analysis; it is difficult to justify the full-time employment of risk management professionals within SMEs especially the smaller ones.*

Our study focused on a few main themes including “awareness level”, “internal policy”, “identification of financial and operation risk”, “risk analysis, evaluation and treatment” and “risk monitoring and review”. This article however for space limitation does not deal with all of these items.

### **Past Research- Some discussion**

The Institute of Chartered Accountants in Wales and England has been, and continues to be, a major contributor to the debate on managing business risk.

In their briefing document on “*Risk Management for SMEs*” in October 2002, it summarises the recent work by The Faculty of Finance and Management looking at current practice in risk management. The Faculty first published a comprehensive guide

“Business Risk Management” in 1996 when the topic was in its infancy. This is one of the first documents to view business risk management as a cross-organisational technique rather than a narrow, mainly financial discipline. This work has influenced our questionnaire development.

Since that work, risk management has become established as a core business activity. However, there is little guidance on how companies should best manage risk, who should be responsible and where to turn to for advice.

### **Definition of Operational and Financial Risk Management**

Risk management is a central part of any organisation’s strategic management. It is the process whereby organisations methodically address the risks attaching to their activities with the goal of achieving sustained benefit within each activity and across the portfolio of all activities.

Major companies, together with academics and professionals, have produced control systems, which although varying in shape and detail between different industries, generally define the following two risks in this manner.

Operational risks arise from the various operational and administrative procedures that the business uses to implement its strategy.

Financial risks arise from the financial structure of the business, from transactions with third parties and from the financial systems in place.

### **Hypotheses & Analytical Model**

Given that the competitive level in Singapore is high and tough and the fact that all respondent companies are reasonably well established( they are mid-size by our small economy standard), we will make the following hypothesis or somewhat loosely, propositions, for our conclusions will be based mainly on subjective opinions, though widely collected through face to face interview:

**Hypothesis 1:** SMEs will manage their operational risk factors reasonably well. We define a null hypothesis as more than 50% awareness level or a score more than 18 in operational risk factors average( more explanation later).

**Hypothesis 2:** SMEs will manage their financial risk factors reasonably well. We define a null hypothesis as more than 50% awareness level or score more than 15.50 in financial risk factors.

**Hypothesis 3:** SMEs will manage their overall risk factors reasonably well. We define a null hypothesis as more than 50% awareness level or score more than 70 in overall risk management factors.

**Hypothesis 4:** SMEs in different sectors will show differences in regard to their risk management awareness eg financial organizations will be more aware of their risk exposures for the volatility factor, manufacturing in Singapore is almost entirely export dependent etc

Note that the hypotheses would be valid for more established SMEs, while they may not stand for less established ones.

The possible outcomes can be realized from our surveys; the actual findings either support or reject our hypothesis, or partially one or the other.

While this study is focussed on measuring the level of awareness of risk, actual use of risk management techniques are not part of this study, though were discussed generally.

### **Possible Errors of Results**

While every effort has been made to ensure the errors are kept to a minimum, we speculate the following potential problems:

- a. Accuracy of data- opinions are subjective though mostly derived from top management level
- b. Interviewing the right people
- c. Dealing with the wide scope of risk management- how well the respondents really understood them
- d. Limited to one person's view, in a company
- e. Risk management policy is not promulgated across the organization.

### **Research Methodology**

We have designed one survey instrument for this project, which is conducted to find out the awareness level of the SME on risk management issues. Interview was face-to-face, at the highest possible level in each firm we could reach, and one person in each( this had its merits and demerits). It was difficult to find a quite similar research in the literature, but our consultation of related literature helped developing the survey instrument and our discussion among ourselves. Our long experience in dealing with SMEs' various

insurance needs also helped, the long association with them. Hence the research is based more on the ground than literature alone. We are all practising men.

### **SME Survey- More Explanations**

We used a set of potential scale items rated on a 1-5 scale for each question. These items consist of the importance and significance of various operational and financial risk management techniques used in SMEs.

The rating we assigned to each of the item is as follow:

| Rating | Selection by Owner about the type of business insurance or other risk management techniques |
|--------|---|
| 1      | Strongly disagree   |
| 2      | Disagree  |
| 3      | Neutral   |
| 4      | Agree   |
| 5      | Strongly agree  |

The final score for the respondent on the scale is the sum of their ratings for all of the items (sometimes called a "summated" scale).

Altogether there were 23 questions in different sections. For each individual respondent, the minimum score is 23 and the maximum score is 115 (23 X 5).

We define the awareness level as follow:

|          |              |
|----------|--------------|
| 23 – 40  | Unacceptable |
| 41 – 60  | Fail         |
| 61 - 80  | Fair         |
| 81 - 100 | Good         |
| 101- 115 | Excellent    |

We define level of awareness to be high if a respondent score a rating above 70.

### **Sampling of Business Owners**

A sampling size of 65 business owners was selected using a combination of convenience(for we knew them) and the simple random sampling method, out of which, 2 were public listed company, 37 private limited companies, 8 partnerships and 18 sole-proprietorships. Finally however, 61 instruments could be used meaningfully, the rest rejected. We spent, on our reckoning, nearly 250 man-hours on data collection effort alone, collectively.

The possible outcomes below can be realized from our surveys: the actual finding either supports or rejects our hypothesis or partially one or the other.

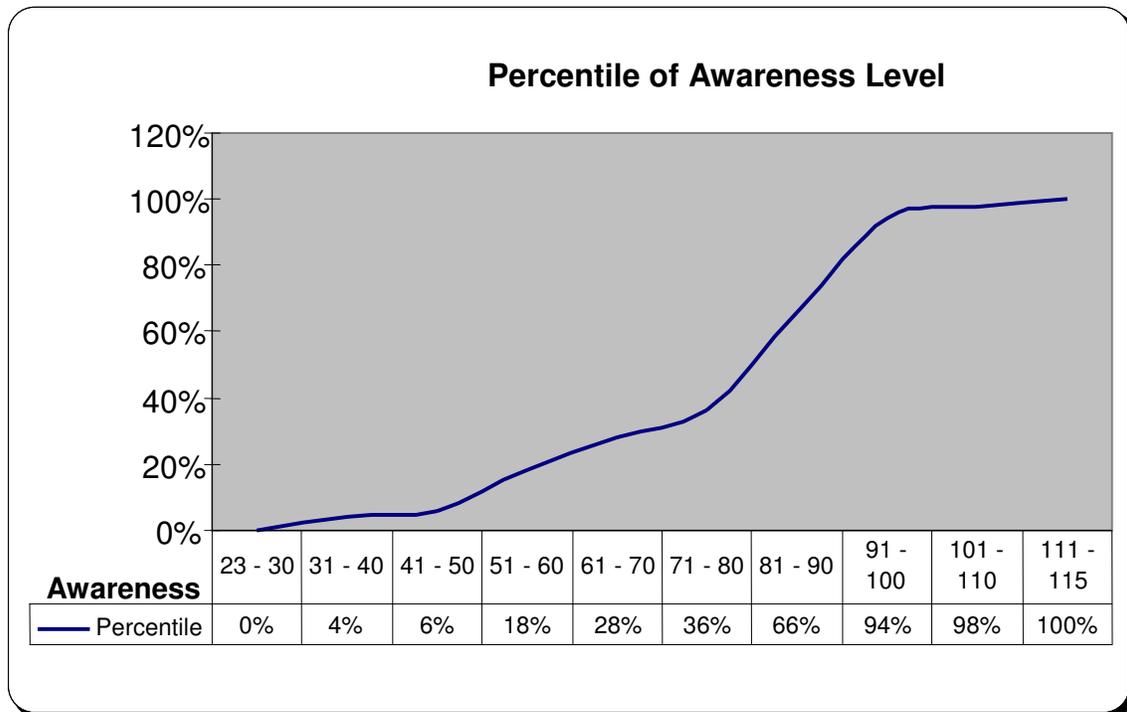

## Data Analysis

### Business Owners' Survey

The number of business owners involved in this survey is 61.

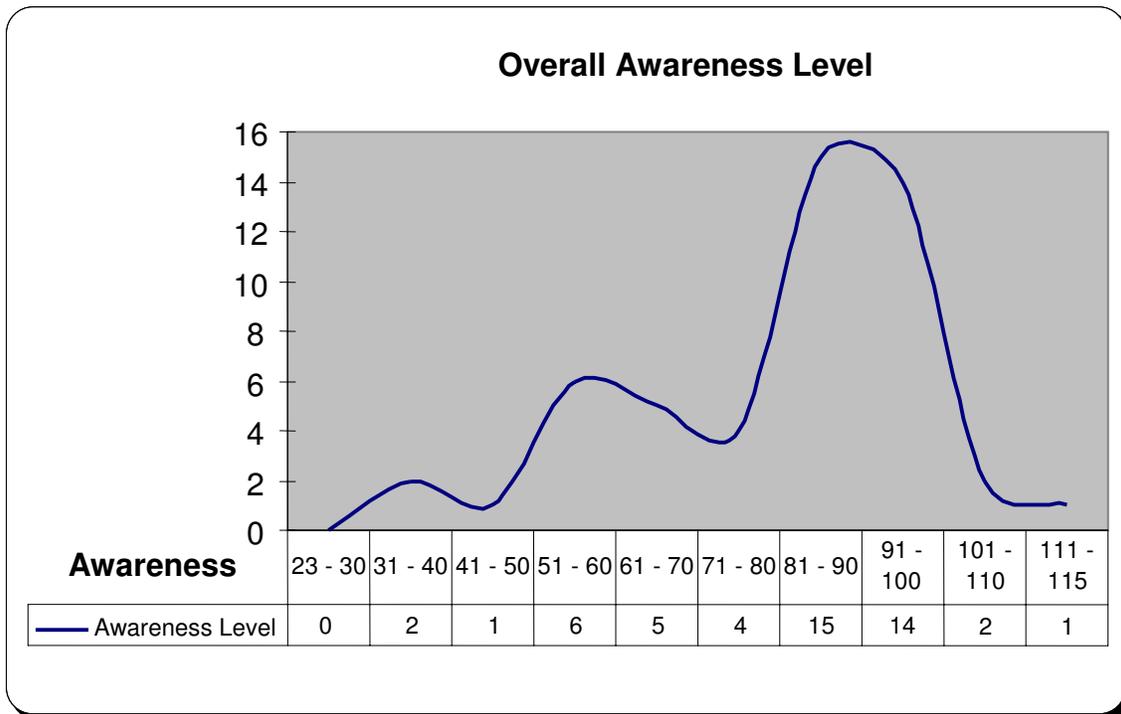

| Overall Awareness Level- Total score | Number | Percentage | Cumulative percentage |
|--------------------------------------|--------|------------|-----------------------|
| 23 – 30                              | 0      | 0%         | 0%                    |
| 31 – 40                              | 2      | 4%         | 4%                    |
| 41 – 50                              | 1      | 2%         | 6%                    |
| 51 – 60                              | 6      | 12%        | 18%                   |
| 61 – 70                              | 5      | 10%        | 28%                   |
| 71 – 80                              | 4      | 8%         | 36%                   |
| 81 – 90                              | 15     | 30%        | 66%                   |
| 91 – 100                             | 14     | 28%        | 94%                   |
| 101 – 110                            | 2      | 4%         | 98%                   |
| 111 – 115                            | 1      | 2%         | 100%                  |

**Table 1. Cumulative Percentage of the all respondents**

Based on the data collected, only 28% of the business owners' score below 70 points based on a scale of 21 - 120 for awareness level, which means that 72% of the respondents' awareness level is considered high. Thus, it is obvious that in general, business owners have a fairly high level of awareness on risk management issues.

### Hypothesis or Proposition Testing – Overall Awareness Level

Sample size = 61;    Mode = 85;    Mean = 80.08;  
 Median = 84;    Standard Deviation = 17.94

### Interpretation of Hypothesis Testing

|                            |              |
|----------------------------|--------------|
| <b>Sample Size:</b>        | <b>61</b>    |
| <b>Mode:</b>               | <b>85.00</b> |
| <b>Mean:</b>               | <b>80.08</b> |
| <b>Median:</b>             | <b>84.00</b> |
| <b>Standard Deviation:</b> | <b>17.94</b> |
| <b>Hypothesized Value:</b> | <b>70.00</b> |
| <b>Significance Level:</b> | <b>0.10</b>  |

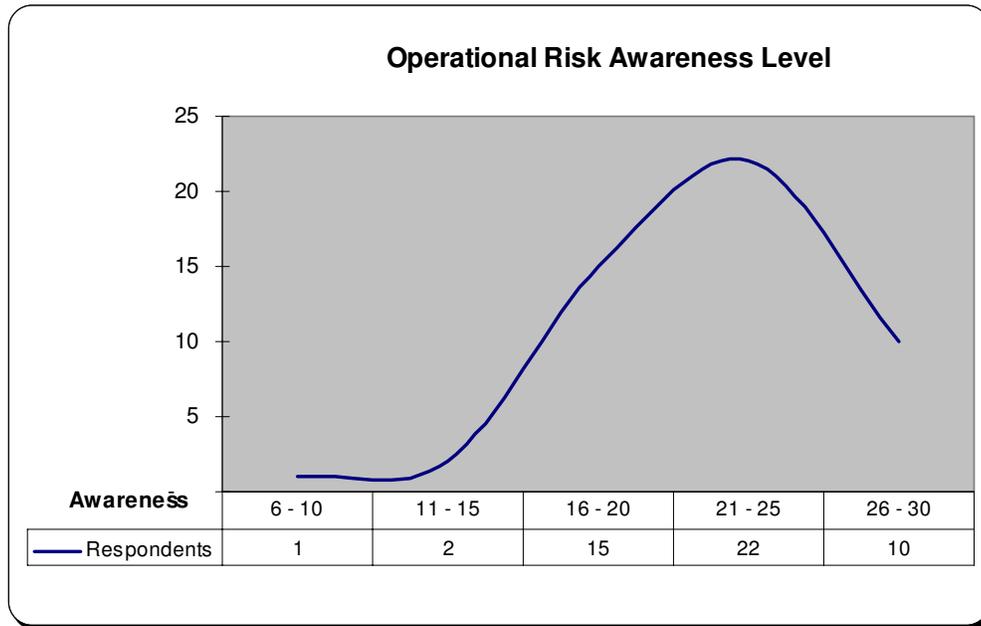

### Student's t-Distribution

$$\begin{aligned} \text{Acceptance Range} &= \text{Hypothesized Value} \\ &+ t\text{-Value (Std Dev}/\sqrt{\text{Sample size}}) \\ &= 70 + 1.299 (17.94/\sqrt{61}=2.3) = 72.99 \end{aligned}$$

*[Note: The t-value of distribution is 1.299 for one-tailed probability of 10% with 60 degree of freedom]*

The Sample Mean of 80.08 exceeds this range; therefore we accept the null hypothesis. This means that the level of awareness on Risk Management issues by SMEs in Singapore is high. However, this acceptance of a high level of awareness is based on subjective opinions which may or may not be fully informed, hence we would rather it a call it a proposition generally well proved. This observation remains valid throughout in this paper.

### Hypothesis Testing – Operational function

Sample size = 61;    Mode = 23;    Mean = 21.54;  
 Median = 22;    Standard Deviation = 4.99

### Interpretation of Hypothesis Testing

|                            |               |
|----------------------------|---------------|
| <b>Sample Size:</b>        | <b>61</b>     |
| <b>Mode:</b>               | <b>23.00</b>  |
| <b>Mean:</b>               | <b>21.54</b>  |
| <b>Median:</b>             | <b>22.00</b>  |
| <b>Standard Deviation:</b> | <b>4.99</b>   |
| <b>Hypothesized Value:</b> | <b>18.00*</b> |
| <b>Significant Level:</b>  | <b>0.10</b>   |

\* Hypothesized value, or acceptance cut-off point in each section is obtained by the section's number of questions, and using its mean value as a guidance. In this section there are 6 questions.

**Student's t-Distribution**

$$\begin{aligned} \text{Acceptance Range} &= \text{Hypothesized Value} \\ &+ t\text{-Value (Std Dev}/\sqrt{\text{Sample size}}) \\ &= 18 + 1.299 (4.99/\sqrt{61}=0.64) = 18.63 \end{aligned}$$

[Note: The t-value of distribution is 1.299 for one-tailed probability of 10% with 60 degree of freedom]

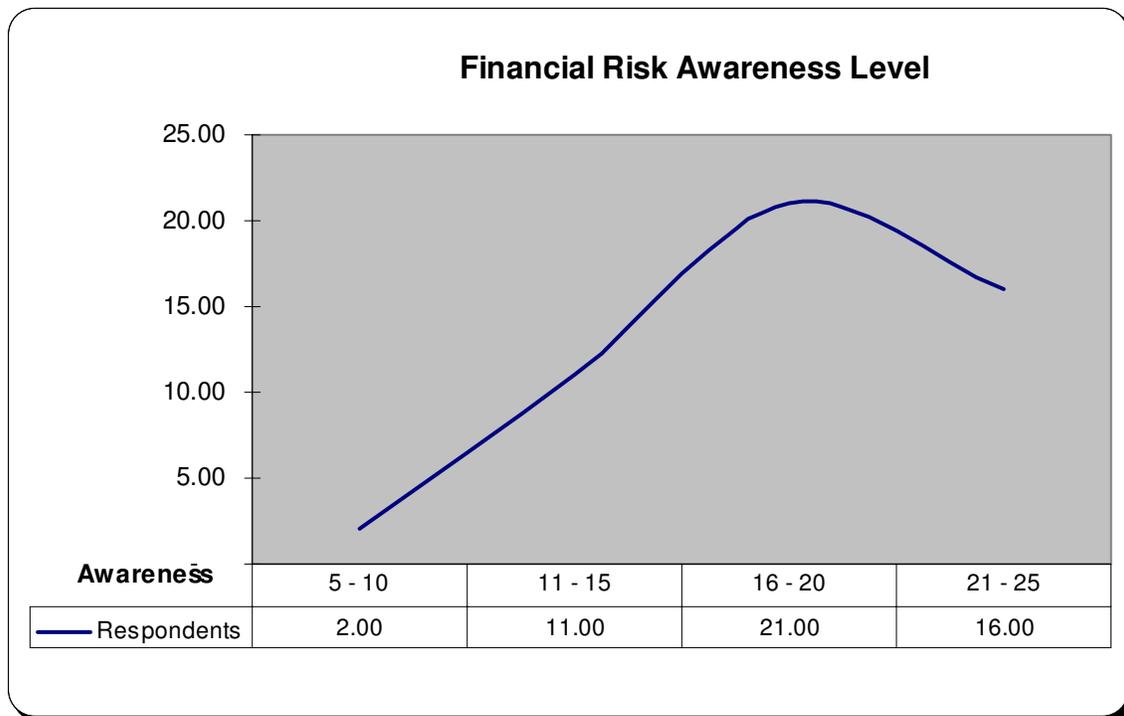

The Sample Mean of 21.54 exceeds this range; therefore we accept the null hypothesis. This means that the level of awareness on Risk Management issues in the area of operational functions by SMEs are high.

Alternatively, we can measure the Test Statistics to determine the acceptance level as compared to the appropriate t-value of distribution.

$$\begin{aligned} \text{Test Statistics} &= \frac{(\text{Sample Mean} - \text{Hypothesised Value})}{(\text{Std Dev} / \sqrt{\text{Sample Size}})} \\ &= (21.54 - 18)/(4.99/\sqrt{61}) = 5.0163 \end{aligned}$$

The t-value of distribution is 1.299 for one-tailed probability of 10% with 60 degree of freedom. Since the test statistic is more than t-value, we accept the null hypothesis. This means we can conclude that the SMEs are aware of the Risk Management issues in the area of operational functions.

### Hypothesis Testing – Financial function

Sample size = 61;    Mode = 18;    Mean = 18.54;  
 Median = 19;    Standard Deviation = 4.44

## Interpretation of Hypothesis Testing

|                            |              |
|----------------------------|--------------|
| <b>Sample Size:</b>        | <b>61</b>    |
| <b>Mode:</b>               | <b>18.00</b> |
| <b>Mean:</b>               | <b>18.54</b> |
| <b>Median:</b>             | <b>19.00</b> |
| <b>Standard Deviation:</b> | <b>4.44</b>  |
| <b>Hypothesized Value:</b> | <b>15.50</b> |
| <b>Significant Level:</b>  | <b>0.10</b>  |

### Student's t-Distribution

$$\begin{aligned}\text{Acceptance Range} &= \text{Hypothesized Value} \\ &+ t\text{-Value (Std Dev}/\sqrt{\text{Sample size}}) \\ &= 15.50 + 1.299 (4.44/\sqrt{61}=0.58) = 16.33\end{aligned}$$

*[Note: The t-value of distribution is 1.299 for one-tailed probability of 10% with 60 degree of freedom]*

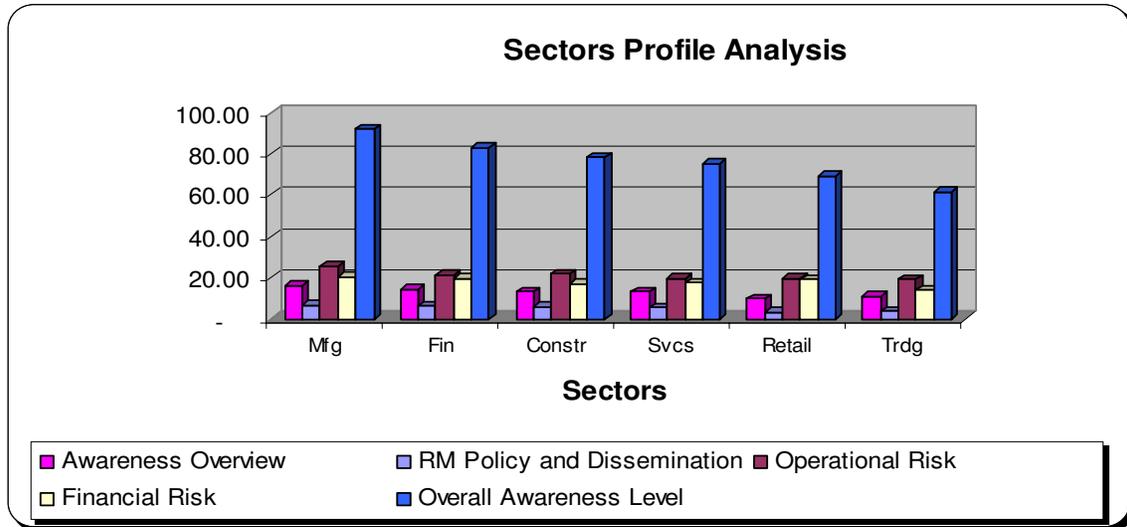

The Sample Mean of 18.54 exceeds this range; therefore we accept the null hypothesis. This means that the level of awareness on Risk Management issues in the area of financial function by SMEs are high.

Alternatively, we can measure the Test Statistics to determine the acceptance level as compared to the appropriate t-value of distribution.

$$\begin{aligned}\text{Test Statistics} &= \frac{(\text{Sample Mean} - \text{Hypothesized Value})}{(\text{Std Dev} / \sqrt{\text{Sample Size}})} \\ &= (18.54 - 15.5)/(4.44/\sqrt{60}=0.58) = 6\end{aligned}$$

The t-value of distribution is 1.299 for one-tailed probability of 10% with 60 degree of freedom. Since the test statistic is more than t-value, we accept the null hypothesis. This means we can conclude that the SMEs are well aware of the Risk Management issues in the area of financial functions.

### Business Sector Analysis

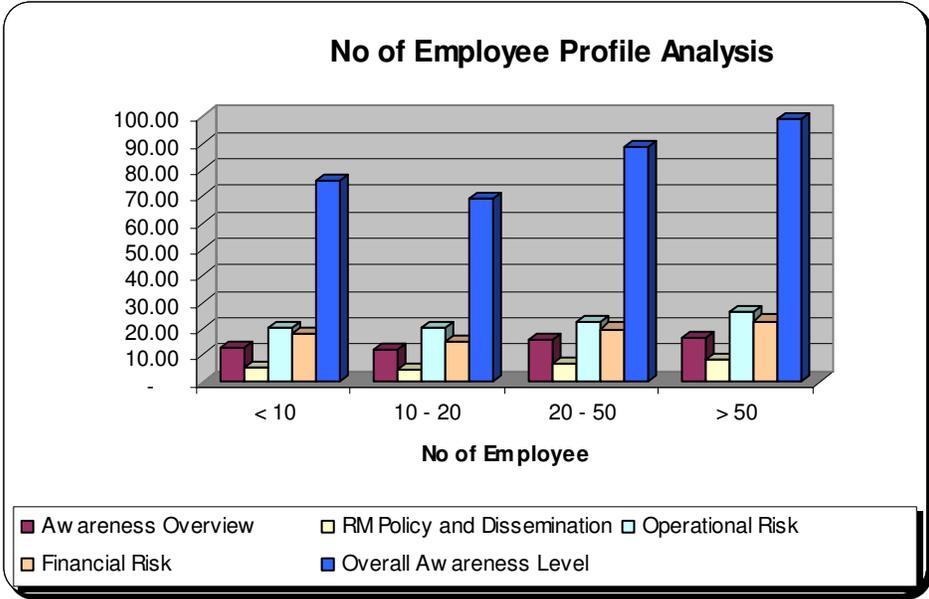

The awareness levels for the various industries shown above are as follows: manufacturing (92.08), finance (82.88), construction (78.00), services (75.32), retail (69.33) and trading (61.50). As predicted, the more sophisticated industry including manufacturing, finance and construction, which tend to be confronted with visible business risk factors and are more aware and actively managing business risk. On the other hand, less volatility-dependent sectors( in Singapore context) including services, retail and trading show somewhat less prepared for risk exposure. However, one limitation is that our sample in each sector was too small to confirm this finding more definitively. Hence, the related hypothesis is allowed with reservation.

### Other Analyses

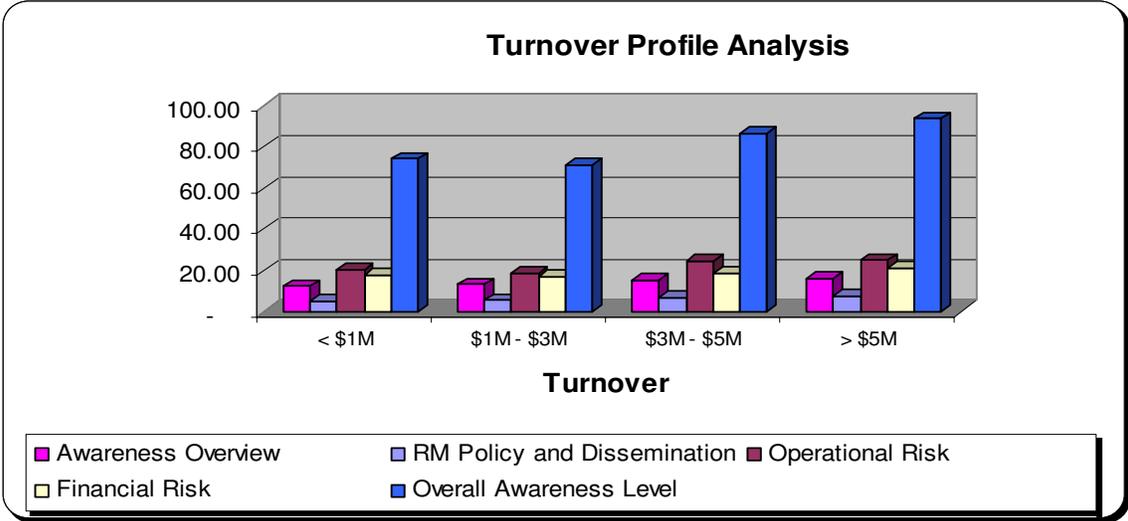

Surprisingly, the level of awareness on risk management issues are not significantly different when related to years in business. Statistics shows the following: those in business < 5 years scored 81.53; 5 to 10 years in business scored 78.78; 10 to 20 years in business scored 79.60 and greater than 20 years in business scored 79.44. From the results, we can conclude that there is no significant correlation between number of years in business and the awareness level of SMEs on risk management issues.

### Number of Employees

The chart indicates that there is increasing awareness as the number of employee increases. The statistics show the following: companies with less than 10 headcount scored 76.00; 10 to 20 headcounts scored 69.33; 20 to 50 headcounts scored 88.33 and those greater than 50 headcounts scored 98.83. We can conclude that risk awareness and number of employees in a company are correlated.

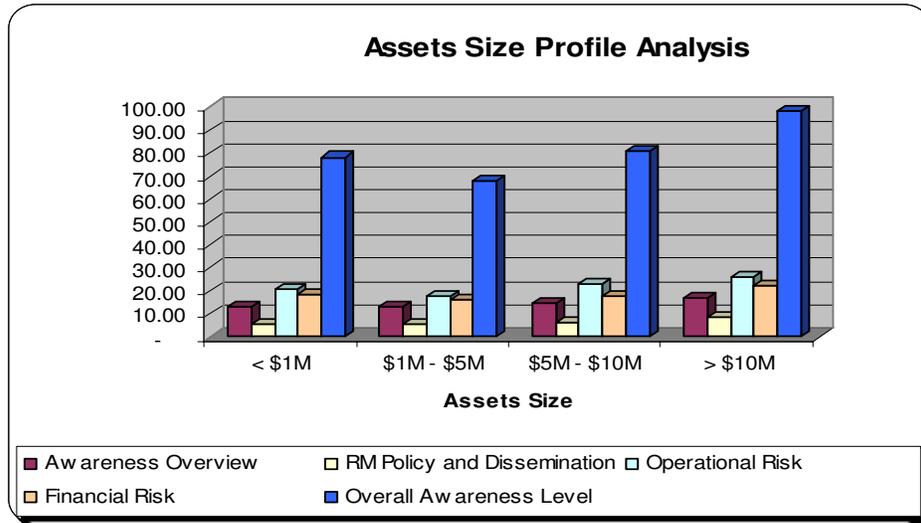

**Sales Turnover**

Generally, as annual sales turnover level increases, the awareness level of the companies on risk management issues also increases. Statistics show the following, companies with sales turnover of less than \$1 million scored 74.20; turnover of \$1 million to \$3 million scored 71.09; turnover of \$3 million to \$5 million scored 86.67 and turnover of greater

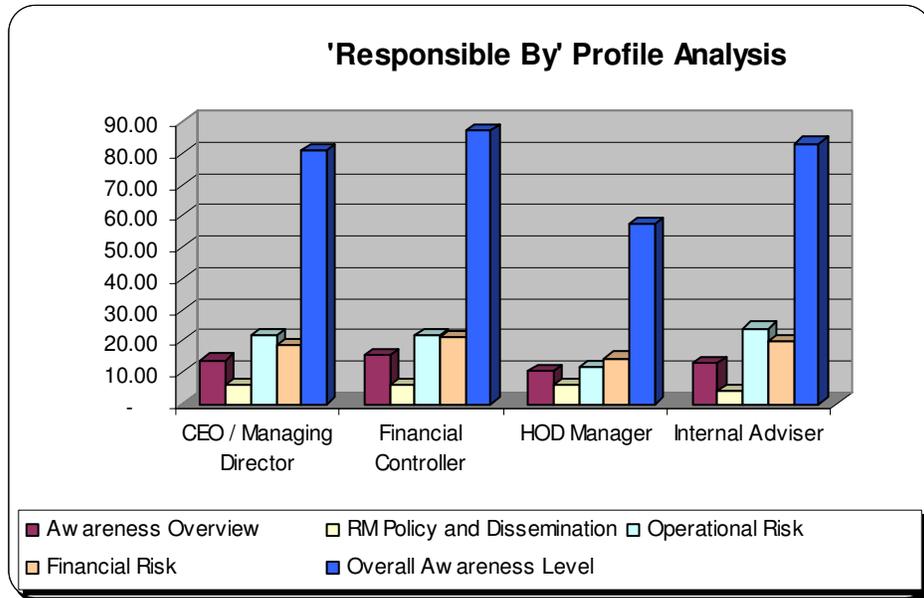

than \$5 million scored 93.69. We can conclude that that the size of business and risk awareness level is also correlated.

### Asset Size

As in sales turnover analysis, the awareness level of the companies on risk management issues also increases as assets size increases. Statistics show the following, companies with assets size of less than \$1 million scored 78.15; assets size of \$1million to \$5million scored 67.75; assets size of \$5million to \$10million scored 80.83 and assets size of more than \$10million scored 98.50. Hence, it is also possible to conclude that the size of assets employed in a business and its risk awareness level will be correlated.

### Person Responsible for Risk Management- as our discussions revealed

The chart above does not show any significant correlation between the companies awareness level and the personnel responsible for managing risk management issues with one exception. One finding that is significant in this analysis is that the awareness level scored is significantly lower when HOD( Head of Deptt) manager handles it. The score is at a low of 57.50 as compared to average score of 83.60. We can conclude that the level of authority vested in the HOD manager might have caused the implementation of risk management policy within the company to be less effective. Therefore it is critical that risk management policy should be placed under the responsibility of key officer(s) such as CEO, core management team or designated Internal Adviser in order for the policy to be effectively adopted and implemented throughout the company-wide. As if echoing this sentiment, writing to an accounting journal( Accounting & Business, Oct 2004,UK, Pp10), Gereme Howe, a senior business manager based in UK says “someone has to take the central role....tasked with coordinating risk assessment and mitigation across the business.. Without this role, organisations will struggle to demonstrate to their trading partners and customers that they are safe to do business with..”.

## Conclusion Findings

Based on our analytical studies of the survey results, it confirms our hypotheses that given the tough competitive business environment in Singapore, and given our respondents are generally well-established midsize companies, we conclude that:

- a. Overall Risk Awareness Level  
Our SMEs( as defined in this research in Singapore context) have scored satisfactorily, hence the hypothesis that they are sufficiently aware is accepted.

- b. Awareness Level in Operational Risk  
--Same observation as above
- c. Awareness Level in Financial Risk  
Same observation as above
- d. Operational awareness varies between industries, increases with the size of employees and assets.
- e. Level of management exercising control over risk management is a key issue.

As a general conclusion we can state that risk management has become and is increasingly becoming a major management issue for all businesses, and certainly for SMEs everywhere. Even then, it must be categorically stated that high enough level of awareness of risks does not necessarily mean appropriate actions always since they can be so varied and sometimes very expensive too coupled with the fact that in the SME sector especially, there may well be ignorance in some respects.

#### A Postscript on Tsunami and its effects on SMEs in Asia

What Tsunami has done to Asia is deadly. It's another gentle reminder of Risk Management that we could learn from all the researchers and scientists around the world. Tsunami affected area around Asia was scary and will be remembered by everyone around the world. Why were there no warnings? Why were there no signs? Why were there no immediate help by the local country authorities? Why there was not enough information from the time Tsunami hit Asia? Those and other questions are being looked at.

Our preliminary investigation in Sri Lanka and Thailand shows devastating losses suffered by coastal-based smes who suffered from lack of insurance against tidal waves. Many of them have been wiped off the slate and never to come back. It happened after the main paper was written already, but underlines the need for risk management by smes against shocks in business. Apparently, many large hotels in Maldives were unaffected for they had adequate protection but small businesses in Thailand were not protected, never indeed thought of it and paid a final price for un-managed risks, the bane of all businesses.

### Risk Management Questionnaire

|          |             |
|----------|-------------|
| Company: | Interviewee |
| Date:    | Interviewer |

In our MBA dissertation project with Vancouver University, we are studying the awareness of SME owners with regards to the importance of managing risk in financial and operational aspects. In this survey, we assess your company on risk management from different perspectives.

The questionnaire covers the following segments:

1. Awareness Overview
2. Risk Management Policy

3. Risk Identification
4. Risk Analyses, Evaluation and Treatment
5. Risk Monitoring and Review

Only pay attention to the issues that are relevant to your company. As a memory arises, write down arguments, additional information and decisions concerning correctives measures on a separate piece of paper. All data collected will be kept confidential and used for analysis only.

**Profile of the Organization**

### Questionnaire

#### 1. Awareness Overview

This section seeks information on the awareness overview of risk management by your organisation.

|   | Strongly Disagree | Disagree | Neutral | Agree | Strongly Agree |
|---|-------------------|----------|---------|-------|----------------|
| 1.1 Your organization's risk management is anticipatory. [i.e. matters are improved before the problem arises]?                       | 1                 | 2        | 3       | 4     | 5              |
| 1.2 Your organization's risk management is monitored and reported as part of the normal Management reporting system?                  | 1                 | 2        | 3       | 4     | 5              |
| 1.3 Your organization's adopts other risk management method are used as appropriate, in addition to insurance cover being considered? | 1                 | 2        | 3       | 4     | 5              |
| 1.4 Your organization uses consultants, insurance companies and other experts when need arises?                                       | 1                 | 2        | 3       | 4     | 5              |

#### 2. Risk Management Policy

This section seeks information about your policy for risk management and how that policy is promulgated throughout your organisation.

|                             | Strongly Disagree | Disagree | Neutral | Agree | Strongly Agree |
|-----------------------------|-------------------|----------|---------|-------|----------------|
| 2.1 Your organisation has a | 1                 | 2        | 3       | 4     | 5              |

documented risk management policy approved by CEO and Board/Executive Management Team.

### 3. Risk Identification

This section asks questions about how your organisation identifies the risks it faces:

| 3.1 | In identifying risks, your organization does consider the following sources of risk:       | <b>Strongly Disagree</b> | <b>Disagree</b> | <b>Neutral</b> | <b>Agree</b> | <b>Strongly Agree</b> |
|-----|--|--------------------------|-----------------|----------------|--------------|-----------------------|
|     | Operational [risks associated with delivery of services]                                   |                          |                 |                |              |                       |
|     | ♦ compliance risk [the risk of failing to meet government standards/laws and regulations]? | 1                        | 2               | 3              | 4            | 5                     |
|     | ♦ public liability risks [public access, safety]?  | 1                        | 2               | 3              | 4            | 5                     |
|     | ♦ natural hazard risks [climatic conditions, earthquakes, bushfires, floods, vermin]?      | 1                        | 2               | 3              | 4            | 5                     |
|     | ♦ technological risks [innovation, obsolescence, explosions and dependability]?            | 1                        | 2               | 3              | 4            | 5                     |
|     | ♦ human risks [strike by employees, loss of key personnel]?                                | 1                        | 2               | 3              | 4            | 5                     |
|     | ♦ security risks [premises/computer breaches]?   | 1                        | 2               | 3              | 4            | 5                     |
| 3.2 | In identifying risks, your organization does consider the following sources of risk:       | <b>Strongly Disagree</b> | <b>Disagree</b> | <b>Neutral</b> | <b>Agree</b> | <b>Strongly Agree</b> |

| ♦ markets risks [risk arising from exposure in stocks, commodities, foreign exchange markets and use of derivatives for hedging purpose]?                            | 1 | 2 | 3 | 4 | 5 |
| ♦ liquidity/credit risks [the marketability of assets to be converted to cash and the ability to honor contractual agreement for settlements.]?                      | 1 | 2 | 3 | 4 | 5 |
| ♦ reporting risks [capture timely and accurate data in meaningful format to provide information for decision-making purposes. Includes tax: regulatory, accounting]? | 1 | 2 | 3 | 4 | 5 |

#### 4. Risk Analyses, Evaluation and Treatment

This section seeks to establish the extent/scope and responsibilities for risk analysis, evaluation and treatment in your organisation.

- |     |   |                          |                 |                |              |                       |
|-----|---|--------------------------|-----------------|----------------|--------------|-----------------------|
| 4.1 | Does your company organise risks in terms of: | <b>Strongly Disagree</b> | <b>Disagree</b> | <b>Neutral</b> | <b>Agree</b> | <b>Strongly Agree</b> |
|     | ♦ Consequence: formally or                    | 1                        | 2               | 3              | 4            | 5                     |

**Risk**

The chance of some occurrences that will have an impact on the overall achievement of organisational objectives. It is measured in terms of the likelihood of something happening and the consequences if it happens. Risks can be negative [that is having an adverse impact such as loss or harm] or positive [that is a gain or advantage].

**Reputation Risk**

The risk associated with potential damage to the organization's credibility and reputation.

**Risk Alliance**

The risk associated with working with partnering organisations.

**Opportunity Risk**

The risk associated with lost opportunity.

**Compliance Risk**

The risk associated with failure to meet government standards and regulations.

**Risk Analysis**

Determining the level of risk following consideration of the sources, consequences and likelihood of risks.

**Risk Criteria**

Measures/standards set by the organisation to rank risks and decide whether they are acceptable or not.

**Risk Evaluation**

Comparing the level of risk with the risk criteria and deciding whether the risks are acceptable or unacceptable.

**Risk Financing**

The methods applied to fund risk treatment and the financial consequences of risk.

**Risk Identification**

The examination of all sources of risk facing the organisation from any activity, functions or processes undertaken.

**Risk Management**

A systematic and logical process of identifying, analysing, evaluating, treating, monitoring and communicating risks associated with any activity, function or process in a way that will enable an organisation to minimise losses and maximise opportunities.

**Risk Management Champion**

A senior executive, manager or similar person (or team) who supports the effective development, implementation and review of the risk management framework within the organisation.

**Risk Management Framework**

Management policies, procedures and practices applied by the organisation to the task of identifying, analysing, evaluating, treating, monitoring and communicating risks.

**Risk Management Plan**

A document which sets out the:

- strategic context and objectives for risk management
- risks identified/analysed/assessed/prioritised as having critical impacts on the organisation
- plan to manage strategic and important risks.

**Risk Management Policy**

A document that defines the organization's strategy and provides guidance for risk management.

**Risk Treatment**

The selection and implementation of appropriate options for dealing with identified risk.

**Stakeholders**

Individuals, groups, institutions etc (either internal or external to the organisation) who are or perceived to be affected by a decision or activity.

**Acknowledgement:**

Our MBA dissertation group would like to take this opportunity to express our sincere thanks to the following people and all others who have in one way or another help to contribute to the completion of the dissertation:

1. Prof B. C. Ghosh and Prof Tan Wee Liang for mentoring us through the dissertation.
2. SME owners and corporate executives for providing us the data to complete our survey.

# CHALLENGES TO THE GROWTH OF FINNISH WOODWORKING SMES

## ABSTRACT

The present paper is based on series of woodworking SME studies that have addressed woodworking SMEs in various segments in Finland and in eight European countries. Finland has a relatively large number of woodworking SMEs whether calculated as enterprises per 1000 inhabitants, or as a proportion of all enterprises and so should have a basis for the development of SMEs in the woodworking sector. The challenge is how to create growth from this endowment of knowledge and experience.

The challenges of international restructuring of industrial production, with the customer demands for components on a JIT-basis have been recognised Finnish SMEs. The main business problems recognised in the international study were not considered to be serious in Finland, with the exception of economic performance. The institution environment for SMEs was also considered to be fairly good, although national level institutional support was considered to be weak in Finland, local, practical SME support was considered to be strong.

The future success of the Finnish woodworking industries depends on domestic demand. This can be stimulated by changes to planning legislation and building regulations to encourage the building of wooden single-family homes adjacent to the urban growth centres as well as encouraging the building of wooden apartment houses in towns.

The external economies that benefit firms in industrial concentrations are not to be found in the Finnish woodworking sector. Such industrial concentrations that currently exist are not expected to develop further. This creates a weakness that could effect the sectors' ability to grasp these new opportunities.

## INTRODUCTION

With its large forest resources, Finland has long been a strong player in the global forest industry, a situation that is set to continue in the foreseeable future. However, this success is largely based on the efficient, capital-intensive production primary manufactured goods (paper, pulp, sawn timber and wood-based panels) for the export market. The labour-intensive, secondary value-added production takes place in the export countries. Thus, the export of primary-manufactured products for secondary, value-added manufacturing elsewhere, is a *de facto* exportation of jobs. This is evident in the fact that 1000 m<sup>3</sup> wood raw material creates c. 2 jobs in Finland whereas in Denmark, for example, where the same amount of wood creates employment for 37 people. Denmark has only a small domestic forest industry, concentrating on secondary value-added manufacturing based imported semi-finished wooden products (Selby & Petäjistö 2002).

The Finnish domestic woodworking industry is largely dependent on the level of construction activity. A major component in this equation is the construction of domestic housing. Legislation, fashion and values each play a role in peoples' choices when purchasing or constructing a family house. Consequently, the promotion of wood as a building material is a major factor in the success of woodworking industries. In larger-scale buildings and constructions, wood has considerable potential, but it has to be made competitive with concrete and steel not only in terms of price and engineering, but also with respect to construction industry skills and logistics. Also until recently building legislation has been unfavourable for wooden housing. There were about 34 000 jobs in the woodworking industry at the turn of the century. These were located in just over 5000 enterprises with an average turnover of five million euros.

The present paper is based on a series of Finnish studies that have addressed domestic woodworking SMEs in various segments (Mäkinen & Selby 1995, Mäkinen 2002), as well as how the institutional environment for Finnish woodworking SMEs compare with those in some other EU member states (Selby & Petäjistö 2002). The latter study enabled the relative strengths and weaknesses of the institutional environment for SMEs to be assessed.

## CHALLENGES TO SMES IN A CHANGING BUSINESS ENVIRONMENT

### Changing business environment

The changing international markets for goods, and the speed of the capital markets, have led to a weakening of traditional location constraints and traditional divisions between capital, R&D, manufacturing and sales. These developments have changed the international small business environment over the past two decades, as large corporations and the manufactures of standard mass-production have downsized their operations and use sub-contractors (e.g. Howard 1990, Sengenberger et al. 1990, Rodríguez-Pose 1994). Industrial production is increasingly concentrated in SMEs(SMEs=less than 250 employees) that are re-emerging in a post-Fordian industrial regime based on innovative technology, skilled labour and high value-added products. In this context, a country's capacity to build strong production networks constitutes a new kind of competitive advantage (Porter 1990).

The rapidly changing business environment nevertheless creates considerable uncertainty and increased complexity that, in turn, presents greater challenges to both individuals and firms as they try to understand and cope. The main challenges, following Gibb (2000) occur at every level of the business environment, global, societal, organisational and individual. The changing environment for business therefore presents a number of challenges to which entrepreneurs and enterprises will need to respond as they will affect not only the factors of production structure of the firm, but also the structure of their industrial segment or even perhaps the structure of the whole sector of industry.

To survive and grown in this dynamic environment, the firm has to be able to acquire and assimilate a large amount of information, and to achieve this it has to become a “learning organisation”. Social and political institutions can help firms adopt or invent new procedures and so create conditions that encourage industrial enterprise both nationally and in specific regions.

### **National and local institutional contexts**

The allocation of economic activity (whether public or private) is very much a question of political organisation (Urry 1984;53). Regionally-based, or sector-oriented, organisations can therefore play an important role in the process of economic change. Existing start-off conditions, which are part of a historical process, may play an essential role in an area’s receptivity to and assimilation of innovative trends and process (Rodríguez-Pose 1994;329).

Innovation not only relies on the capacities of a few individuals and companies to invent new procedures and compile masses of information, but also on the capacity of new industrial production structures to supersede old ones and their ability to respond to challenges. The current development of a nation, region or a locality is the outcome of how different production systems, social and political regimes, and cultures have been successfully combined spatially (Rodríguez-Pose 1994;329).

Local industrial development can, however, only operate in the context of the parameters which define the national production systems within which firms and workers operate. These differing modes of production will have resulted from variations in labour-management relations, production strategies, systems of industrial financing, and public-private sector relations. Uncompetitive national models of production may be slow to change. Consequently, local economic development becomes a question of how to overcome the national structural constraints by the development of small-scale co-operative networks at the local community level (Ettlinger 1994, Ettlinger & Patton 1996).

### **Information and knowledge acquisition**

Because the R&D resources of SMEs are invariably limited, to acquire the necessary knowledge, information and skills, SMEs must rely on having access to information and knowledge flows. Such flows can be accessed on a random, or “need to know” basis, or they can have regular and continual access to information flows. One way to secure such flows is membership of a branch or sector organisation that is committed to developing both the sector, the segment and its members interests. Another solution has been the formation of geographical concentrations of industry (industrial districts) (Marshall 1920, Markusen 1996, Parc 1996). These have succeeded because of the external benefits that are to be obtained from the social, economic and technical synergies that result from proximity effects. A major benefit of the agglomeration process is the development of a milieu that stimulates localised

learning - the local flow of knowledge and information within a sector or branch (e.g. Trigilia 1992, Lorenzen 1998). The means employed by firms to acquire knowledge and information are many and varied, being passive (trade fairs, the media) or active (proximity effects,) to active sources (courses, R&D projects). Sources may be informal (customers, family & friends, neighbouring firms) or formal (financial institutions, R&D projects, etc.). Firms also have varying degrees of receptiveness to knowledge as well as varying abilities to benefit from the knowledge they have (Selby 1989, Cohen & Levinthal 1990). Informal sources of information and knowledge are not to be underestimated, as research on weak-ties have demonstrated (Grannoveter 1973). As these linkages develop, inter-firm trust is established which becomes a cumulative process further advancing the synergy effects of the agglomeration (e.g. Sabel 1992, Lorenzen 1998).

### **AIM OF THE STUDY**

The addresses the following questions:

1. Are regional concentrations to be seen in woodworking sectors and have the benefits to be derived from such concentrations been recognised and developed?
2. What is the institutional environment for business in Finland especially in wood working sectors?
3. What kind of business problems are the Finnish woodworking industries facing?

### **MATERIAL**

The survey was made in 1999 by mailed questionnaires and interviews of 65 organisations representing woodworking industrial branches in eight European countries: Austria, Denmark, Finland, Germany, Ireland, Italy, Sweden and the United Kingdom. The questionnaire was developed in conjunction with partners in each country. The two main problems to be solved were a) adjusting the theoretically oriented questions to the reality on the ground in each country, and b) compatibility of the questions after translation into the domestic language. A wide range of organisational structures was represented, ranging from single, centralised organisations, often representing more than one industrial branch, to countries with a plethora of organisations representing every branch or craft, at national, regional or even local levels (Selby & Petäjistö 2002).

The countries were selected subjectively on the basis of prior knowledge of their woodworking industry, their tendency to form industrial districts, and their labour input intensity coefficient (the number of jobs created by 1000 m<sup>3</sup> solid raw wood equivalent of domestic timber). Italy and Austria also have specific legislation for SMEs, while Ireland was included because of the rapid growth of the wooden furniture industry around an incipient industrial agglomeration. Fifty-six usable questionnaires were returned.

Other data concerning forest and woodworking SMEs in Finland were collected by interviews and mailed questionnaires, by sectors, over a period of years (Mäkinen 2002). The study concerning the builders' carpentry and joinery sector that forms the basis of this paper was made in 2000 (Petäjistö et al. 2001).

## RESULTS

### Direction of development

Post-Fordian production regimes, under which production networks based on flexible specialisation become a central feature of production structures, have been identified to a greater or lesser degree throughout the European woodworking sector. Countries in which the woodworking branches are strongly adjusting to this new production regime can be considered to in a more favourable position than those in which adjustments are not seen to be so important. On the basis of the question *In what direction(s) do you think industrial production will develop in your branch during the next five years in order to maintain or improve its competitiveness?* It was possible to construct three principle components: 1 - Component-specialised JIT-networks, 2 - Market-oriented JIT-networks, and 3 - Region concentration of production (Selby & Petäjistö 2002)(JIT=Just in Time). The components support Steiner and Solem (1988) who noted that the success of small manufacturing firms depends upon specialising in products, markets and/or customers.

With respect to the development of *component-specialised JIT-networks*, industry representatives in Austria, Finland, Denmark obtained the highest mean component scores, that is to say, these countries most strongly recognised this direction of development. As the differences in the means scores was statistically significant at  $p=0.07$ , these three countries should gain some competitive advantage by following this development.

Similarly, with respect to *market-oriented JIT-networks* representatives in Finland, Austria, Denmark and Germany obtained the highest mean scores, while in Sweden, UK, Ireland and Italy, such a trend is considered to be less likely (negative mean scores). However, as the differences in the means were not statistically significant. This implies that no country has a distinct advantage or disadvantage in this respect.

*Region concentration of production* is often seen as a major advantage to any SME-based industry. Organisations in Denmark, Germany and Italy considered that regional concentration of production is likely to occur in future. The result is interesting given that Danish and Italian woodworking SMEs already have strong regional concentrations. Finnish, Austrian and Swedish representatives did not consider that regional concentrations were likely to develop. In the Finnish case, the result is supported by studies of the woodworking industry by (Kautonen 1998, Selby & Petäjistö 2002 and Packalén et al. 2003) despite the presence of a distinct potential for regional concentrations of the builders carpentry & joinery and wooden furniture sectors (Figure).

FIGURE about here

These later results are interesting in that studies of forest and woodworking enterprises in various sectors have revealed not only inter-firm co-operation on a number of aspects of business, but also the opinion that such co-operation is beneficial, especially with respect to supplies, but also with respect to information exchange, marketing and some aspects of production (Mäkinen 2002). In the builders' carpentry & joinery sector over a quarter of the self-assessed "successful" firms engaged in regular inter-firm co-operation, where as the moderately or less successful firms engaged in much less inter-firm co-operation (Petäjistö et al. 2001).

## **Institutional environment and national political support**

In the comparative study, representatives were asked: *How does your organisation perceive other organisations'/groups' attitudes with respect to developing the preconditions for SMEs?*

It was assumed that where institutional attitudes towards SMEs are perceived to be favourable (or at least neutral), then a branches' interaction with the institutions of the corporate state should lead to institutional structures which support SMEs, e.g. via policy instruments favourable to SMEs. On the other hand, where institutional attitudes are unfavourable, then it is likely that the institutional position of SMEs will be perceived to be weak. The responses were reduced to basic dimensions using principle component analysis. Two well defined components were obtained: 1 - Local level (practical) organisations, and 2 - National level support, which contained mainly national level interest groups (Selby & Petäjistö 2002).

*Local/practical support* for woodworking SME development was considered to be strongest by Finnish, Italian, Danish and German representatives (highest mean component scores) and less strong amongst Irish, Swedish, Austrian and British representatives. The difference in national means were significant at  $p=0.03$ . Thus, by maintaining or developing its standard of local level (practical) infrastructure, Finnish woodworking SMEs would appear to have an opportunity to obtain a competitive advantage.

In the case of the *National-level support*-component, the differences between national means were not statistically significant, so that there should be no major competitive advantages or disadvantages for the countries in this respect. Where national level support for SMEs to be developed, then clear advantages should be forthcoming.

With respect to public sector incentives for SMEs representatives were presented with a set of likely incentives with the question: *Have the following types of public sector support for small businesses been actively taken up in your industrial branch.* Four principal components were obtained: 1 - Start-up incentives, 2 - Staff-training and development incentives, 3 - Re-location incentives, and 4 - Tax relief (Selby & Petäjistö 2002).

With respect to star-up incentives, Italian and Finnish representatives experienced the most positive situation. The differences between country means were statistically significant at  $p=0.00.$ , and so countries with high mean score should have more favourable conditions for SME formation. The result reflects the fact that, of the countries in the study, Italy and Finland had the greatest number of woodworking enterprises both as a percentage of all industrial enterprises and as the number of enterprise units per 1000 inhabitants. Also, because of a deep economic depression in the 1990s that resulted in high long-term unemployment, Finnish employment policy has sought to increase the creation of small enterprises.

Concerning *industrial re-location incentives*, Swedish, German and Austrian representatives considered their countries' to have the most favourable incentive schemes for assist firms to re-locate. Such schemes support regional development, but they would also be important to assist with the creation of regional industrial networks, industry concentrations or industrial districts. Finland has low priorities in this respect.

*Staff training and development incentives* did not vary significantly between countries. This implies that competitive advantage would be gained by any country that assisted SMEs invest in human resources, e.g. via vocational education.

As vocational education can provide a pool of skilled labour as well as helping to create a new generation of entrepreneurs (Gibb 1993, 2000), representatives were asked: *In your experience, is the vocational education system supportive of small businesses?* A five-point scale from strongly supportive to strongly unsupportive (via "neutral") was employed.

Of the Finnish replies, only 17% considered vocational education to be (at best) mildly supportive of small business, while two-thirds of the Finnish replies considered vocational education to be mildly prohibitive. Italian representatives, too, reported dissatisfaction with vocational education, with 23% reporting a strongly unsupportive situation and the remaining 77% reporting the situation to be mildly unsupportive. Only German and Irish organisations reported strong support for small business from vocational education. These countries also report a mildly supportive system, so that their overall satisfaction was high. The results indicate that corrective actions are required if Finnish woodworking SMEs are to have access by suitably qualified employees.

Finnish woodworking enterprises are only partly aware of the problem. Just over a third of SME entrepreneurs in the builders' carpentry & joinery sector took part in development courses in 1999 (of which 11% were technical courses and 20% management courses) (Petäjistö et al 2001). However, there was a strong correlation between participation in courses and turnover. Over 80% of entrepreneurs of firms with a turnover greater than 1.6 million euros took part in course compared to only 10% of firms with a turnover of less than c.170 000€. A similar result was obtained with respect to the training of employees. In firms that were self-assessed as "successful", 85% trained their staff in-house via apprenticeships or other training schemes, while in firms that self-assessed as "less successful" only 1 firm (10%) had trained staff in-house, nor had this firm employed vocationally trained employees (Petäjistö et al. 2001).

## **Business problems of woodworking SMEs**

### *Problem identification*

To assess the nature of the problems that were perceived to be facing SMEs in the case study countries, representatives of the industrial organisations were asked the question: *To what extent are the following issues seen as problems in small businesses in your industrial branch?* A number of alternatives were presented that were derived from earlier studies and the international SME literature. Representatives could also add their own specific issues, but few felt the need to do so. As the problems facing SMEs are not singular, principal component analysis is again employed to examine the inter-relations between sets of problems. Four dimensions were identified by principle components: 1 - Concern over production substitution and raw material supply, 2 - Concern over factors of production, 3 - Concern over coping with regulations, 4 - Concern over economic performance.

*Concern over product substitution and raw material supply* was greatest amongst Italian, Austrian and German representatives. The least concern as amongst Irish representatives. The Irish result is logical given that forest industries have been developed in close cooperation with the state forest authority (Growing for the Future 1996) and the wooden products are largely based on woodfibre (MDF, etc.).

*Concerns over factors of production* (labour supply and costs, and the maintenance of skills and technology) were greatest amongst Swedish, Italian and Irish representatives, and least amongst German, Austrian and British representatives. The difference between country means was statistically highly significant, suggesting these problems need to be taken seriously in the countries concerned.

*Concerns about coping with regulations, standards and norms* (e.g. ISO 9000 & 14000, and EMAKS) were greatest amongst Austrian, Irish and Italian organisations. Finnish and Swedish firms reported the least problems. It is tempting to conclude that because Finnish and Swedish firms are dominated by LSEs, there has been a better ability to apply resources to adjust to new norms and regulations, and that relevant information has thus been well disseminated throughout the industry (LSE=large scale enterprises, more than 250 employees). The difference in the country means was statistically significant.

*Concerns over economic performances*, notably profitability and competitiveness were strongest amongst Danish, Finnish, German and Swedish representative organisations. Austrian, Italia and especially Irish organisations received scores below the mean, i.e. the problem was perceived to be less important. The result for the Irish case is logical given that the data was collected in the 1998-9 when that country's economy was growing at c. 8% per annum. The Austrian woodworking industry was also expanding at the time of the investigation (Petäjistö et al. 1997, Petäjistö et al. 2002).

In a study of the Finnish builders' joinery & carpentry sector (Petäjistö et al. 2001), a common problem reported by SMEs concerned *product marketing*. A lack of knowledge of the markets was reported by 26% of the self-assessed "successful" enterprises, but this figure rose to 70% of the self-assessed "less successful" enterprises, of which 40% reported this to be a serious problem. Virtually the same figures were repeated for "marketing skills". Forty percent of the "successful" firms nevertheless reported some problems with their marketing skills. When assessed on the basis of firms' turnover, all of the firms with a turnover of over 1.6 million euro reported a lack of knowledge of markets, with 40% considering the problem to be serious. Just over a fifth (23%) of the firms in the 168 000 - 1.6 million euro class reported no problems with knowledge of the market, but 46% considered their lack of knowledge to be a serious problem. Over three quarters of the smallest group (less than 168 000 €) considered lack of knowledge of the markets to be serious.

The profitability and competitiveness of Finnish woodworking firms is a problem not fully recognised at the firm level in the builders' carpentry and joinery sector. Most of the firms studied at the end of the 1990s reported that their profitability and other performance parameters would either remain the same or improve in the future (Petäjistö et al. 2001).

However, a recent report suggests otherwise, with the large number of small firms crating intense inter-firm competition via pricing, and that this is reducing the profitability of the woodworking sector (Pohjois-Pohjanmaa Liitto 2004).

## DISCUSSION

The Finnish woodworking sector is characterised by a relatively large number of woodworking SMEs. Whether calculated as enterprises per 1000 inhabitants, or as a proportion of all enterprises, Finland has almost as many wood working enterprises as Italy,

and more than Denmark - both countries famous for their proliferation of woodworking SMEs. Finland therefore seems to have a basis for the development of SMEs in the woodworking sector. The challenge is how to create growth from this endowment of knowledge and experience.

Finnish woodworking industry organisations recognised that the industry was moving towards a market-oriented-JIT economy. Similarly, they recognised that the market would be increasingly oriented toward component production on a JIT basis. The higher awareness of these trends, in the face of the restructuring of international markets can only be considered as a strength. How the industry responds to these changes, of course, is the main challenge.

In several countries, major benefits to the woodworking sector have been obtained by regional concentrations of SMEs. An analysis of the distribution and location of employment and enterprise in Finland's wood products and furniture SMEs indicated that regional concentrations already occur in certain branches. Despite this, few of the benefits have been obtained (Kautonen 1998, Packalén et al. 2004). Finnish organisations do not consider that increased regional concentration of production is likely to occur, which suggests that they, too, have failed to recognise the benefits of such concentrations. Conversely, in Denmark and Italy, where the woodworking industries have obtained considerable benefits from concentration into industrial districts, representatives consider that regional concentration will continue. Finnish woodworking enterprises are activity engaged in inter-firm co-operation, however, but this has not yet led to widespread external benefits. The institutional environments of some of the Finnish regional agglomerations are currently being developed to further improve the knowledge infrastructure and to encourage networking amongst woodworking SMEs. Even inter-regional links are envisaged to facilitate R&D transfers to SMEs.

There remains a number of entrepreneurs who have negative attitudes towards networking, and attitudes are changing very slowly (some firms refuse to learn). In the Schumpeter tradition, these firms may cease, thereby making way for young innovative firms that can benefit from, and help to create, a constructive knowledge environment.

Of the various types of business problems facing woodworking SMEs, Finnish woodworking organisations' main concern was the general problem of competitiveness and profits. With respect to other problems, such as coping with administration & regulations, product substitution, and human resources (availability, competence and costs), Finnish concerns were below the average of woodworking organisations in other European countries. The results fail to reveal the specifics of different woodworking sectors. For example, the wooden house sector is currently performing rather well, while the wooden furniture industry suffers from severe price competition that is reducing profitability. Both sectors suffer from a large number of small firms that compete with each other, thereby reducing profitability. This problem could be overcome by increased networking, with synergy effects and external economies (Pohjois-Pohjanmaan Liitto 2004).

Many existing firms have growth potential, and a number of woodworking SMEs have demonstrated their ability to succeed in the export market. Such firms have nevertheless had to undergo considerable production and managerial renewal. The healthy regeneration of the woodworking sector also requires new entrants into the sector. Reflecting their concern over competitiveness, Finnish organisations consider that woodworking entrepreneurs required training in business management skills. Previous research has demonstrated that woodworking firms often possess good technical skills, but are weak on management

practises (e.g. Selby 1989, Selby & Petäjistö 1992). Training in the ability to cope with changing standards and regulations that are associated with the development of the Single Market are also required.

Finnish woodworking industry organisations considered that there was rather poor national political support for woodworking SMEs, possibly reflecting the LSE dominance of the forest industry sector. The strong institution position of LSEs have ensured that the institutional environment supports their interests a more national-level political support for their SMEs (Passila 2000). Lobbying is not practiced by Finnish woodworking SME organisations (Selby & Petäjistö 2002); perhaps it should be. On the issue of local-level, practical support, Finnish organisations reported a satisfactory situation (despite a lack of local branches). Finnish organisations should continue to develop this relative strength. There is evidence of a major change in the institutional response to SMEs and wooden construction in Finland. The governmental Entrepreneurship Policy Programme seeks to improve the preconditions for entrepreneurship, while a major six-year programme for the Advancement of Wood Use addresses the development of the wood products industry, the advancement of wooden buildings, and the marketing of wooden products in Europe.

Finnish woodworking organisations are fairly satisfied with the institutional environment for business, although Italian, German and Austrian woodworking are more satisfied with their countries' institutional environments. These latter countries also have specific SME oriented business legislation. The result is contradicts the World Economic Forum's Global Competitiveness Reports that have usually ranked Finnish industry very highly while Italian industry usually gets a poor assessment (the WEF inquiry largely concerns the LSE environment). The result of the present investigation are more in line with the findings of the Global Entrepreneurship Monitor (Arenius et al 2001), even though this does not operate at the sector level. According to GEM, in 2003 Finland ranked fifteenth out of 30 countries with respect to the total level of entrepreneurial activity. Limited to Europe, Finnish enterprises were ranked fifth, ahead of both Danish and Italian enterprises.

To cope with a rapidly changing business environment, both globally and domestically, Finnish woodworking SMEs have to be well endowed with information and skills that concern not only their industry, but also business skills to cope with the changing demands of the institutional environment (new industrial norms, legislation, etc.). They also need to have the skills to negotiate participation in vertical and horizontal production chains. This requires then to find the balance between inter-firm co-operation and competition. The more successful firms, and also firms with larger turnovers, have taken steps to acquire managerial skills, and to train employees. Such activities have features less in smaller and less successful firms, raising issues of cause and effect. Similarly, despite Finnish society being at the forefront of ITC use, woodworking SMEs were still surprisingly limited in their use of ITC at the beginning of the decade. The increasingly close interaction between customers, firms and suppliers envisaged by current trends in both the global and domestic business environment demands that greater competence in the use of ITC is acquired (Petäjistö et al. 2001, Teriö et al. 2005).

The learning and adjustment processes required by Finnish woodworking SMEs should be motivated by the fact that the wooden products industry still faces a number of opportunities. In the builders' carpentry and joinery and wooden house sector, opportunity is being provided by changes in society. The increasing prosperity of society is creating demands for detached houses in areas adjacent to the growing urban centres. In 2002, only 12% of such houses were constructed of bricks or other mineral materials, while 57% were wood-frame houses, and

20% wood-element houses, the remaining 11% being log houses. To expand this sector, however, new planning legislation is required to make suitable land available. Another development is toward wooden apartment buildings, and to encourage this trend, new building regulations are required. In other words, many of the opportunities rest with institutional decision makers rather than in the individual firms. Once these opportunities are made available, the woodworking firms must be ready to respond to the challenge.

**ABSTRACT**

This study investigates the span of delegation and control of owner/managers in small and medium-sized enterprises (SMEs) and compares the practices of owner/managers in family-businesses to those in non-family businesses. While too much centralization in a firm can lead to unmotivated employees and decision-making bottlenecks, too little management oversight can lead to frustration as employees flounder to make decisions with little guidance or direction. Although small businesses in general have problems delegating and determining an appropriate level of control, research indicates that family-business owners may be even more controlling. In a study of SME owner/managers, the authors use Rasch analysis to examine the concentration of authority in these firms and develop a measurement scale to identify the centralization and delegation practices of the owner/managers. Specifically, this study finds that family-business owner/managers both maintain more centralized decision-making and delegate differently than their non-family counterparts. The paper also shows how an individual owner/manager can use this study's results to compare his/her delegation practices with those of study respondents.

## INTRODUCTION

Past research has shown that one of the key challenges for small business owners is determining an appropriate level of management control (e.g. Daily & Dalton, 1992). When founding owners begin firms, they typically do everything. However, as they add staff members, owners must learn to delegate to other managers and subordinates. Too much centralization in a firm can lead to unmotivated employees and decision-making bottlenecks, resulting in poor firm performance and even firm failure. Conversely, if managers delegate too much, employees can find their jobs frustrating as they flounder to make decisions with little guidance or direction (Schultz & Schultz, 2002). This also leads to poor performance.

While small businesses in general have problems delegating and determining an appropriate level of control, research indicates that family-business owners may be even more controlling (e.g. Dyer, 1986; Daily and Dalton, 1992; Upton and Heck, 1997). Because these owners are concerned about family matters in addition to business matters, they often have problems releasing control to subordinates. Such problems may be worsened by pressures to hire from within the family and/or make decisions that prioritize family control and wealth over enlightened operational and strategic management.

This study investigates the delegation and control practices of owner/managers in small and medium-sized enterprises (SMEs) and compares the practices of owner/managers in family-businesses to those in non-family businesses. In general, we believe that family-businesses are less likely to delegate and more likely to maintain a centralized decision-making process than non-family owner/managers.

## METHODOLOGY

The evaluation of centralization practices among SMEs was conducted as part of a larger study of practices among such firms. Seven hundred forty-five executives from a sample of 321 firms in a large Southwestern market were mailed a nine-page, multiple-construct survey. Responses were received from 167 executives. Of these, 124 were usable for this analysis: 57 from family firms and 67 from non-family firms. The sample consisted primarily of owner/managers (n=111) as well as a small set of non-owner senior managers (n=13). The average number of employees for all of these firms was 69, ranging from 1 to 2000. Ninety percent of the executives (112 firms) reported that their firms had fewer than 100 employees. Because analysis of delegation practices in one and two-person firms is inappropriate, twelve respondents who indicated that their firms had fewer than three employees, were excluded. In addition, the authors removed 26 respondents because Rasch analysis indicated that their response patterns showed unexplainable misfits. "Misfits" are those respondents who seem to misuse the survey instrument by indicating inappropriate response patterns or who limit their responses to the extremes of the instrument's scales (Wright & Masters, 1982). The final sample included 41 family firm respondents and 47 non-family-firm respondents.

Within the larger survey instrument described above, eleven questions were from an Aston studies-based organizational structure scale intended to measure the degree of centralization in a firm (Inkson, Pugh & Hickson, 1970). Factor analysis (principal components, quartimax

rotation) revealed that these eleven questions all loaded on to the same factor, thus indicating that they measured dimensions of the same construct. As will be discussed below, Rasch analysis was used to optimize the scale for use among SME owner/managers.

## ANALYSIS

The authors performed Rasch rating scale analysis using Winsteps 3.21 software. Rasch, named after the method's founder Georg Rasch, is an analysis technique used for developing linear measures (Smith, 1999). Rasch rating scale analysis compares measures on a common logit scale similar to characteristics of conjoint measurement. While researchers often use the technique for developing models in education and in health sciences, Rasch has not been widely used in the business sciences. As an evaluation tool, individuals can compare their results with a model's scale to determine how they compare to their peers or to desired performance levels. In simpler terms, Rasch rating scales perform similarly to standardized test scales used in college placement exams.

### Instrument Evaluation

This section discusses how the authors used Rasch analysis to evaluate the Aston studies scale to determine if the instrument could be used in SMEs. The Aston scale examines task performance practices at six organizational levels: board of directors or owner, chief executive, divisional or functional manager, sub-department head, first-level supervisor, and operative. Because many of these levels may not exist in SMEs, analysis first examined if the levels were appropriate for this study. Analysis revealed that of the six levels in the instrument, "sub-department head" was never the most probable response. Given that 90% of respondent firms had fewer than 100 employees, it seems unlikely that the organizational structures of the SMEs included this job title, especially given the instrument also included the level titled "first level supervisor." Correspondingly, the authors recoded both "sub-department head" and "first level supervisor" into one position. This resulted in a five-level scale that worked well for SMEs with infit (*1.86*) and outfit (*1.63*) measures below the prescribed level of 2 (Smith, 1999).

The authors next used polytomous Rasch analyses to evaluate the functioning of the eleven measures in the Aston scale. In many ways similar to factor analysis, polytomous Rasch analysis checks for item multicollinearity and for each item's contribution to the measurement of the latent construct, managerial centralization. Initial analysis yielded an item reliability of .95. Reliability measures are interpreted similarly to Cronbach's alpha in factor analysis. To determine if scale elements are in their natural sequence and to detect if there is multicollinearity, Rasch analysis generates item fit statistics (Wright and Masters, 1982). Infit/outfit analysis revealed that one item, "methods of personnel selection," did not fit the model. The item's overfit is understandable given that the survey instrument also included the item "whether to employ a worker." It appears that if a business empowers managers with the decision "whether" to employ a worker, they also empower the manager to determine "how" to employ that worker. In this respect the two questions, while appearing to measure separate constructs, are multicollinear. As a result, the authors removed the first question, leaving a scale of ten items.

## FINDINGS

## **Overall delegation patterns of SME owners/managers**

The key form map (Figure 1) shows the differences in delegation practices of the SME managers analyzed. To interpret the map, items from the Aston scale are plotted from bottom to top based on the probability that they will be managed at lower levels of management. In rank order from decentralized to centralized, decisions were:

1. allocation of work among available workers
2. overtime to be worked at shop level
3. delivery dates of priority orders
4. machinery or equipment to be used
5. method of work to be used
6. production plans to be worked on
7. whether to employ workers
8. dismissal of a worker
9. the number of workers required
10. internal labor disputes

[Insert Figure 1 about Here]

The scale's validity can be seen by the relatively normal distribution of the "X's" to the left of the line. (Each X indicates the placement of a single subject.) In the center of the scale, the letter "M" indicates the mean rating and each of the letters "S" represents an additional standard deviation from the mean score. The large spaces without items both at the top and bottom of Figure 1 indicate that the scale's content validity and discriminate ability could be improved by adding more items: more strategic items, which are usually performed by the upper levels of management, and more operational items, which are frequently performed by first line employees.

## **Delegation Practices of Family versus non-Family Business Owner/Managers**

To determine if family-business owner/managers delegate differently than non-family business owner/managers, the authors conducted a Differential Item Functioning (DIF) analysis (Table 1). T-tests between the mean logit scores of the two types of firms indicate significant differences in delegation practices for four of the ten items measured: handling internal labor disputes, approving overtime, determining delivery dates, and dismissing workers ( $p < 0.5$ ).

[Insert Table 1 about Here]

To illustrate the rank order differences of the delegation practices of the two groups, Figure 2 looks at the relative ranking of the different items. A solid line connects those items where business practices of the two types of managers vary by more than one rank-order position. The spider-web pattern formed by the lines illustrates how differently the two groups delegate. While owner/managers for both types of firms tend to delegate the determination of job assignments, they handle all other responsibilities differently. The most significant difference occurred in handling employee terminations. While non-family owner/managers reported handling

terminations themselves, family-business managers tended to place that responsibility at the supervisory level.

The scales also show that family-business managers tended to maintain control over tasks typically delegated. For example, family managers reported that more than any other task, they maintained control over production scheduling. Non-family managers tended to delegate the job.

[Insert Figure 2 about Here]

An analysis of the item separations of the logit measures, indicated by each item in parentheses, reveals that overall family-businesses are more centralized than are non-family businesses. After exclusion of the one commonly ranked item, job assignments, family-businesses show much less separation than non-family businesses. For family-businesses, the absolute distance between the logit scores of the second and the tenth items is only .93 logits, while for non-family owned businesses, the absolute difference is 1.47 logits. The narrower score range indicates that decision making in family firms is much more centralized.

### **Individual Assessment Possibilities**

While the scale presented can be used to compare the centralization practices of different types of business structures, it is also may prove useful for use by SME managers to assess their personal delegation practices versus those of their peer owner/managers. To use the scale as such a tool, an individual manager would complete a pencil and paper assessment of the amended Aston scale (Table 2) and compare his/her summed responses to this study results, as seen in Table 3.

[Insert Tables 2 and 3 about Here]

If an individual manager wishes to identify those specific areas where his/her centralization practices differ from those of his/her peers, he/she can transcribe his/her results from the previous instrument to the self-assessment tool in Figure 3. For any individual task score that falls within the unshaded area, that manager's practices are similar to those of this study's peer group. Any results falling into the lightly shaded areas are between one and two standard deviations of the mean, and therefore are either more centralized (for scores to the left) or more decentralized (for scores to the right) than peer group practices. Scores falling in the darkest area are over two standard deviations from mean results. The practices of managers falling in this area are significantly more centralized than those of the study group. Of note, the current scale does not include enough items to identify overly laissez-faire management practices. As discussed in the previous section, the identification of such items could improve the instrument.

[Insert Figure 3 about Here]

## **DISCUSSION—IMPLICATIONS AND LIMITATIONS**

Delegation practices in small businesses can have an important impact on organizational outcomes. Prior research suggests that family business owner/managers are less inclined to delegate than non-family owner/managers (Dyer, 1986). This research supports that conclusion. While both groups showed high levels of managerial centralization, the study found that non-family owner/managers tended to be more empowering than family-business owner/managers. Logit measures from Differential Item Analysis found that the two types of managers delegate responsibilities differently. Family business owner/managers were more likely to delegate hiring, firing, and labor disputes while managing production planning, work methods, and delivery dates. Conversely, non-family business owner/managers were more likely to delegate overtime approval, delivery dates, and equipment scheduling while managing the handling of labor disputes, firing, and hiring.

This study has implications for both theory and practice. In addition to supporting research that indicates that family businesses are more centralized than non-family businesses, this study also indicates that responsibilities are allocated differently in the two types of firms. Another important practical implication involves the use of the Rasch analysis technique to assess factors such as degrees of delegation and centralization. Using the centralization scale, the 10-item pen and paper test, described in Figure 3, can be used by owner/managers to compare their delegation tendencies to those of their peers. Such an instrument could be a useful tool for small business managers and/or consultants.

Analysis of the ten items shows promise for the development of larger scale to measure the degree of centralization/decentralization in SMEs. When comparing practices between firms, the prescriptive centralization measures will vary based upon a number of factors including the education level of the employees and task requirements. Cross-industry validation of this instrument could be used to develop scores for different industries. Once industry benchmarks are developed, struggling firms could evaluate their scores based on those prescribed for the industry. If firm scores are significantly higher or lower than are those of competitive firms, management would be well advised to re-evaluate the level of centralization and control being utilized in the firm

This scale is not appropriate for owners of very small firms with fewer than four employees. In addition, this analysis was only conducted on SMEs. The results, therefore, are most appropriate for companies with between four and one hundred employees. For such firms, however, this model appears to offer promise to be developed into a usable diagnostic for small business owners to determine the appropriate level of centralization for their firms.

## Abstract

Small firms are frequently the source of many significant innovations and it is common for national governments to focus attention upon smaller entrepreneurial firms when seeking to encourage enhanced innovation. However, the entrepreneur within a small firm is frequently resource poor and requires collaborative partnerships with other organisations in order to bring their innovation to market. The role of complementary actors as a part of the firm's strategic network is well recognised as being important to innovation, particularly in the diffusion of new technologies into established markets. This study examines the findings of a pilot study of small, high innovator firms in Australia and their assessment of the risks and benefits of forming strategic alliances with third party complementors. A linear regression analysis found that the entrepreneurs of these small innovator firms were willing to form strategic alliances where such collaboration would assist in reducing customer perceptions of risk in the adoption of their innovation, while also enhancing the customer's understanding of the innovation. However, the entrepreneur of the small firm also needed to be confident that the alliance would allow him or her to retain control over the quality of the final outcome to their customer. These findings suggest that entrepreneur education in the development and management of strategic networks may be a useful enhancement to the process of innovation in small firms.

## INTRODUCTION

Small to medium sized enterprises (SME) (e.g. those with fewer than 200 employees) operate within a web of stakeholders that typically include customers and suppliers, financial institutions and venture capital providers, employees and government agencies (Jennings & Beaver, 1997). Unlike their larger, vertically integrated counterparts, many

SME lack sufficient resources to fully develop all aspects of a new innovation or bring it to market. Entrepreneurs of small firms find it is often advantageous to form strategic partnerships with customers, suppliers and third-party actors that supply finance or even intellectual property to assist the firm to secure a competitive advantage (Ostgaard & Birley, 1994).

This study examined the strategic decision making of entrepreneurs from small firms who were engaged in the commercialisation of a new innovation. A collaborative study involving Australian and French research groups, the project explored strategic risk assessment frameworks originally developed within France (Santi, et.al. 2003) and applied them to a sample of firms drawn from a government database of small innovator firms in Western Australia. The study examined the strategic decision making of the entrepreneurial owners in relation to their risk-return profile (Mazzarol & Reboud, 2005). Particular attention was given to their decision to proceed with a new product or process innovation, and their willingness to engage third party complementary actors in its development and diffusion. Of interest was the role complementary actors might potentially play in the innovation diffusion process.

### **FACTORS INFLUENCING NETWORKING AMONG SMALL FIRMS**

Alliances within networks for small firms can be both formal and informal and can take place across both the production and resource network layers. Given the importance of the owner-manager in the decision to form an alliance, it is within the social network layer that attention needs to be given in seeking to understand the networking of small firms. A personal network – whether formal or informal in nature – is a valuable source of knowledge and ideas for the owner-manager and can assist them in making strategic decisions (Hogberg and Edvinsson 1998).

Common causes of network failure include the attempt by a large focal firm to appropriate the resources of other network partners, or attempt to interfere too much in the operations of their suppliers or distributors. A lack of trust or poor communication between network members can also lead to fatal damage to the alliance. Finally, if the network actors become overly specialised and narrow in their focus, they can lose their ability to innovate and the alliance may see its competitiveness reduced over the long-term (Miles and Snow 1992).

An examination of the strategic networking behaviour of small firms in Europe suggests that entrepreneurs from such businesses are motivated to forge alliances due to social ties built upon family and friends, but this may widen over time to enable the gathering of useful market intelligence. Such networks are both formal and informal in nature and are related to both the customer-supplier relationships and those associated with industry or trade associations and professional agencies (Donckels & Lanbrecht, 1997). A study of Australian small firms found that entrepreneurs are likely to seek strategic alliances in order to either create new market related opportunities, secure access to resources so as to build up business capacity, or defend market position against competitors (Jarrett, 1998).

For many small business entrepreneurs the prospect of forming strategic alliances with other firms is fraught with problems. A common concern appears to be fear that valuable information or intellectual property will be leaked away via the network. This 'leakage' of information is recognised as a major challenge facing business networks and is only really controlled via the trust and mutual respect held among network members. These entrepreneurs may also avoid entering into strategic alliances out of a desire to retain their independence and a perception that other firms could not be trusted (Dean, Homes and Smith, 1997). Manufacturing firms were found to be more likely to avoid such collaboration than service-based firms and older, more established firms were more likely to seek collaboration than younger, less established ones. Entrepreneurs that did engage in strategic alliances expressed the benefits of doing so to achieve sustainable growth and profitability, as well as enhanced information exchange and the improvement of product quality.

A study of 149 small manufacturing firms in the United States found that social networking by the entrepreneurs running these firms was the principal determinant of how strategic alliances were formed. Entrepreneurs who had a high propensity to network were more likely to be engaged in a wide range of formal and informal professional, trade and social organisations. Of importance was their perception that an association in such circles was likely to enhance their prestige. Also important was the strength of the alliances that comprised the network. It was of more importance that the network was focused on valuable outcomes for the entrepreneur than its overall size. Such a network might be focused on production activities or support activities involving marketing, sales, training or investment agreements (BarNir & Smith, 2002).

### **THE ROLE OF COMPLEMENTARY ACTORS IN INNOVATION DIFFUSION**

Brandenberger and Nalebuff (1995) outline the concept of complementary actors within a firm's strategic network. In addition to customers and suppliers, the firm's "value net" contains both "substitutors" and "complementors". The first of these are essentially the competitors who have the ability to substitute the firm's products or services for their own. The latter are those that offer the firm complementary services or whose products or services can complement those of the firm, enhancing the overall benefits to the customers. An example might be that of hotels and airlines, or software companies and those that manufacture computer hardware.

For small firms seeking to commercialise a new innovation it is useful or even necessary to secure access to complementary technologies or resources that can assist the diffusion process. The brilliance or originality of the innovation is often not sufficient to allow a new idea to find ready acceptance within a selected market (Price, 1996). Innovation must be able to meet a market need and must be configured in such a way as to conform to the customer's existing environmental requirements (Grupp & Maital, 2001). Much may depend on the nature of the innovation itself. For example, an incremental innovation may be relatively easy to bring to market without much external assistance. Market disruption is low and customers can readily adopt the product or process with

minimal effort. By comparison a radical technological product or process innovation is likely to be more disruptive of the market and may be more difficult for the customer to quickly adopt, even if it brings substantial benefits to them (OECD, 2001).

Customer acceptance of an innovation – particularly a technological one – is likely to be contingent on their capacity to determine during the selection process five key things: i) the relative advantage of the innovation; ii) how complex it is to understand and use; iii) whether it is compatible with existing technologies and systems; iv) whether it can be trialled before it is accepted; and v) how observable are the benefits from the innovation (Rogers, 1995). In decision making relating to the acceptance of a new technological innovation, the customer is also likely to consider how useful this new product or process is and how easy it can be to use (Davis, Bagozzi & Warshaw, 1989). In some markets the decision as to whether or not a new innovation is adopted may be impacted by the influence of social pressure groups, the brand image associated with the product, how relevant the new technology is to the adopters core business or work, whether the adopter can demonstrate the benefits of the innovation and also the experience the adopter might have with such technologies (Legris, Ingham & Robertson, 2003). Further, within organisations it is common for the adoption decision making to be a two-stage process that involves initially the adopting firm's management, but then the implementation stage in which the end users are engaged (Zaltman, Duncan & Holbeck, 1973; Leonard-Barton & Deschamps, 1988). This can create additional problems for small firms seeking to get their innovation adopted by larger organisations as the diffusion process can be complex.

Complementors can assist the diffusion process by providing a supportive strategic network where the innovation developed by the originator firm is combined with the existing technologies or business systems of a complementary actor in the firm's network. A case in point is that of Australian firm TCG that possessed expertise in electronic metering. To enable them to bring a new product into the aviation refuelling market TCG formed strategic alliances with two complementary actors; a large oil company supplying fuel to the aviation sector and an existing fuel metering manufacturer that did not have the advanced electronic systems offered by TCG. Together the three firms collaborated in the process of new product development. This strategic collaboration enabled TCG to enter this new market that might have been otherwise impossible to access alone (Matthews, 2001).

Based upon this previous evidence this study sought to test several research propositions:

- P<sup>1</sup> – that small innovator firms will seek to implement an innovation strategy where the customer is perceived to secure a significant benefit from the new innovation;
- P<sup>2</sup> – that small innovator firms will seek to implement an innovation strategy where the new innovation is perceived to be compatible with the customers existing technologies or systems;

P<sup>3</sup> – that small innovator firms will seek to establish strategic alliances with complementor networks when the market diffusion may be impeded by above average levels of perceived risk by customers due to the innovation's complexity.

## **SAMPLING & METHODOLOGY**

In 2002 a small scale qualitative study was undertaken in France with 15 entrepreneurs from small firms based in the Dijon region and Paris. The study identified a risk-return evaluation framework for entrepreneurs seeking to invest in a new innovation (Santi et. Al, 2003). This study sought to follow up the earlier French research. In 2004 a pilot survey was conducted with a sample of entrepreneurs from high innovator small firms in Perth, Western Australia. A questionnaire, developed from the original French qualitative study, was distributed to around 550 SME (less than 100 employees, with  $\frac{3}{4}$  of them having under 20 employees, over 80 percent had turnover less than AUD\$5 million, with the average around AUD\$1 million) identified as highly innovative and registered with the WA State Government Department of Industry and Resources (DOIR). A total of 57 usable responses was returned (10% response rate). The majority of respondents was executive managers and owners.

The questionnaire was targeted at persons within the firms who could report on behalf of the entire organisation. Within the final sample 42 percent were owner-managers, 23 percent were executive managers and principal shareholders, 25 percent were executive manager shareholders and 10 percent were executive managers without shareholdings. Thus the majority of correspondents was both executive managers and owners. The questionnaire asked respondents to indicate whether they had an innovation that they were planning to invest in over the next three years, and 96.5 percent indicated that they did so and were planning to introduce a new innovation into the market during this time frame. All firms had introduced a new product or process innovation in the past three years with the average number of new product or service innovations being 4 over the previous three years. The average proportion of annual turn over that these firms invested in new product R&D was 24 percent, reflecting their high innovator status. This should be compared with the Australian industry average of only 0.6 percent (ABS, 2005).

Other questions in the survey were structured around their risk-return assessment of the innovation, as well as the strategic decision making associated with the investment. A particular focus was placed on the role of complementors in the market diffusion process, examining the size of the complementor network, the impact this network was felt to have on the firm's success and the relative importance of the complementors to the innovation.

A step-wise linear regression analysis was employed to test the strength of this complementor network with the dependent variable being the relative importance of complementary actors to the proposed innovation. There were 28 independent variables tested in the regression analysis that related to customer perceptions of the benefits and

risk of the innovation, customer ease of understanding the innovation, their ability to measure the innovation’s benefits, as well as customer and supplier power issues. These variables are shown Table 1.

**Table 1: Independent Variables used in Regression Models**

|  |   |
|--|---|
| <b>Q22</b> value offer to customer                 | <b>Q39</b> supplier power over cost control             |
| <b>Q23</b> price offer to customer                 | <b>Q40</b> customer power over quality                  |
| <b>Q24</b> customer ease of understanding          | <b>Q41</b> customer power over cost control             |
| <b>Q25</b> customer prior test evaluation          | <b>Q42</b> firm power over quality                      |

| <b>Q36</b> customer views of ease of measurement   | <b>Q51</b> importance of sales turnover to customers    |
| <b>Q38</b> supplier power over quality             | <b>Q52</b> importance of sales turnover to firm         |

## FINDINGS

Within the sample, 51 percent indicated that they had entered into some form of joint venture with leading customers, but only 25 percent had entered into any formal joint ventures with key suppliers. Almost half the sample (47%) indicated that they had entered into a joint venture with other companies. This suggests an above average level of strategic alliance building within these firms, which is consistent with highly innovative small companies (Mazzarol 2003). In terms of the number of potential complementary actors that might be involved in the diffusion of the innovation: 69.6 percent of the firms could identify 1-2 partners; 21.4 percent of the firms could identify 3-5 partners; and 8.9 percent of the firms could identify over 6 partners. With respect to the value such complementary actors might offer, 60 percent considered that their value would be high and 40 percent low. Further, 51 percent of the firms considered that these complementary actors would be larger and stronger firms, while 49 percent identified their complementary actors as smaller and more dispersed.

The regression analysis used a stepwise methodology in the SPSS statistics package that produced a model after five steps. It can be seen from Table 2 that this model had an adjusted R-square of 0.42 suggesting that the model explains around 42 percent of the variation in the data. This model suggests that the predictors of the importance of complementary actors to the innovation were:

- The customer’s perception of the level of risk they were likely to face when adopting the new innovation;
- The level of power the innovator firm had over quality within its industry;
- The customer’s perception of the opportunities the innovation would create for them if adopted;
- The compatibility of the innovation to the existing technologies operated by customers; and
- The customer’s ability to easily understand the innovation.

**Table 2: Model Summary**

| Model | R    | R Square | Adjusted R Square | Std Error of the Estimate |
|-------|------|----------|-------------------|---------------------------|
| 5     | .695 | .483     | .420              | 1.512                     |

**Predictors:** (Constant), Q30 customers views of risk, Q42 firm power over quality, Q34 customers views of opportunities, Q27 customer compatibility of technology, Q24 customer ease of understanding

**Dependent Variable:** Overall the relative importance of complementary actors to my proposed innovation is.

**Coefficients**

| Model |  | B      | Std Error | Beta  | t      | Sig. |
|-------|--|--------|-----------|-------|--------|------|
| 5     | (Constant)                               | -3.224 | 1.582     |       | -2.038 | .048 |
|       | Q30 customer views of risk               | .571   | .171      | .391  | 3.341  | .002 |
|       | Q42 firm power over quality              | .504   | .123      | .494  | 4.079  | .000 |
|       | Q34 customer views of opportunities      | .479   | .139      | .412  | 3.452  | .001 |
|       | Q27 customer compatibility of technology | .397   | .150      | .312  | 2.652  | .011 |
|       | Q24 customer ease of understanding       | -.447  | .181      | -.288 | -2.470 | .018 |

## DISCUSSION OF THE FINDINGS

The regression model outlined above suggests that the respondent's assessment of the importance of complementary actors to their proposed innovation is determined by how easily the customer can understand it and the customer's assessment of the risk and potential opportunities offered by the innovation, as well as how easily it can be integrated into their existing technologies. Finally the model suggests that the small innovator firm's own ability to influence the level of quality in the industry plays an important role.

The findings provide support for the research propositions outlined at the commencement of the study, particularly the third proposition. They are consistent with the evidence from innovation diffusion theory that highlights the importance of customers being able to overcome the issues of complexity, compatibility, trial ability and observability in an innovation prior to its adoption (Rogers, 1995). However, where these issues become too difficult to address alone, the innovator firm is likely to seek collaborative partners.

As noted above, previous research into the strategic networking behaviour of small firms in Australia suggests that many find the formation of alliances with complementary actors both confusing and somewhat threatening (Dean, Holmes and Smith 1997). However, such alliance building can provide significant benefits to small firms in terms of enhancing their competitiveness (Ostgaard and Birley 1994).

As previously explained small firms benefit from forming alliances with complementary actors in order to secure access to new markets or product opportunities, to access resources otherwise unavailable to them and to defend established market positions (Jarrett 1998). In markets where the small firm may lack suitable access to key resources, or requires additional enabling technologies to facilitate the adoption of an innovation, collaboration becomes essential. This has been described as a 'triangular' process of new product development, in which the innovator firm collaborates with a third party to secure the adoption and diffusion of their innovation by a potential customer (Matthews 2001).

The findings from this analysis suggest that the small innovator firms in the sample are considering such a process. Where customer's perception of risk is high and their understanding of the innovation is low collaboration is likely. However, the small innovator firm must also be confident that it has an innovation that can offer customers good opportunities and one that will integrate readily into the existing technology base. Finally, the small innovator firm should feel that it could control the quality of the product or innovation within the industry. This last point is likely to be important, because this is likely to provide the small innovator firm with a degree of control over the end result. Should they feel that they couldn't control the quality, they are likely to be vulnerable when engaging complementary actors who might adversely influence the final outcome. The beta score of Q24 "firm power over quality" is not surprisingly the largest within the model.

## CONCLUSIONS

Although tentative, these findings suggest that entrepreneur education in the development and management of strategic networks may be a useful enhancement to the process of innovation in small firms. Small firms benefit from forming alliances with complementary actors but the management of such relationships can be taxing on the entrepreneur and is fraught with potential risks. Teaching entrepreneurs the benefits of strategic partnering and assisting them to find and forge useful strategic alliances should be placed among other management skills in future entrepreneurial education programs.

While only a small scale study, the findings suggest that future research to explore the benefits and impediments to strategic networking among small firms is relevant and useful. Lessons learnt from this research can inform policy makers and entrepreneurs as to the most effective ways to encourage and build alliances. Entrepreneurs need to recognise that the commercialisation of a new – particularly radical – technological innovation is unlikely to be undertaken successfully without the involvement of third party complementary actors. The formation of strategic partnerships with such actors is therefore a strategic management issue that should be addressed early within the business planning process. Policy makers and management educators also need to recognise that the formation and management of strategic alliances is often crucial to the process of successful commercialisation. However, it is frequently viewed as a risky process and assistance processes such as facilitation services that assist entrepreneurs to network in a secure environment can be most helpful. Teaching entrepreneurs the value of strategic alliances and how to manage these from both a legal and social perspective is also important.

**ABSTRACT**

Strategic decision making within small manufacturing firms is a high risk and necessary element for business growth. Small manufacturing firms are more vulnerable when choosing new business paths compared with larger competitors, with superior resources, know-how and finance. Smaller firms must adapt and become more efficient within their current business path and more dynamic in their approach towards finding new paths. Traditional improvement philosophies adopted by many manufacturing firms are widely appreciated as having led to enhanced product quality and reliability. These philosophies, although useful, are not focused on delivering new capabilities or developing new business paths. Learning networks are co-operative associations of partner firms that share knowledge, physical resources and expertise to improve current performance within existing business domains and advance new business paths. Learning networks are advancing the capability of small firms in the polymer industry in Ireland. Ireland has emerged as a significant net contributor of plastics to the global medical device, telecommunications and ophthalmic products sectors. The role of the learning network as a catalyst for both new business development and increased technological enhancement is advanced in this study of an Irish polymer manufacturing firm. The firm is a participant within a learning network called First Polymer Network. The name of the firm has been altered to Mould-Tech for the purpose of this presentation. Adaptation of dynamic learning networks as expounded in this study present participant firms with new opportunities to both '*learn and earn*', i.e. enhance and acquire new capabilities and grow their businesses.

## INTRODUCTION

Strategic change has increasingly been appreciated as a process in which the ability to learn faster than a competitor - is key to competitive success (Eisenhardt, 1999). Over the past two decades, the principal developments in strategic analysis focused upon the link between strategy and the external environment. Prominent examples of this focus are Porter's (1985) analysis of industry structure and competitive positioning. By contrast, the link between strategy and the firm's resources and skills has suffered comparative neglect (Grant, 2002). With the development and maturity of strategic management approaches, it seems clear that a new organisational capability is emerging that is critical to success i.e. the ability to understand and learn from organisational performance (Ulrich & Smallwood, 2004). The ability of an organisation to recognise these capabilities and exploit them through the vision of its leaders will be an essential requirement in a bid to sustain competitiveness.

Traditionally, capabilities-based competition has focused on the development of narrow capabilities based on prior experience, but failed to address how firms cope when existing capabilities become obsolete, or how firms acquire new capabilities (Teece & Pisano, 1994). Much of the work on capabilities has attempted to identify and measure internal components, such as employee skills, know-how and intellectual property. In contrast, there has been relatively little research on capabilities based on linkages with other firms and the position of a firm within a network of organisations. Firms compete in a sector but they can also create a context within which they can co-evolve, especially in areas of capability acquisition (Eisenhardt & Galunic, 2000). As the business environment becomes more complex there is likely to be an increased focus on organisational learning networks as a source of complementary assets and other resources for capability building. With growing complexity in the business environment, the focus on capability building in small firms shifts from capabilities based on internal assets such as R&D activities and intellectual property, to the position of a firm within a network, capabilities based on its relationship with other organisations and the complementary assets of those organisations.

The primary focus of this research study is capability building through knowledge transfer within a Learning Network, entitled 'First Polymer Network' (FPN). Learning has become increasingly important to the survival of firms. The need for learning has yielded a wide variety of alternatives to formal training methods, in contributing to individual and organisational learning.

Firms can no longer be good at everything they must do to meet their customers' needs; they must specialise and learn to combine their capabilities with other firms. Through inter-firm collaboration, networks may allow firms develop solutions to common problems, combine resources to gain knowledge, achieve economies of scale, acquire technologies/resources and enter markets that would otherwise be beyond their reach (McNaughton & Bell, 2001). Learning Networks act as a source of competitive advantage for small firms and help them overcome the disadvantages of size. Cook (1996) found that 'learning through networking' has proven to be an important factor in the economic development of some of Europe's more dynamic regional economies.

## **First Polymer Network (FPN)**

The Polymer industry has become increasingly important in Ireland's industrial structure, employing 11,000 and exporting an estimated €500m annually. The sector is under competitive pressure from low-cost economies including Eastern European countries - some of them new EU entrants. It is also dependent on the fortunes of the industries - electrical, electronics and medical devices - of which it is a supplier.

FPN arose from a government supported initiative to encourage different industry sectors to group together voluntarily to develop their own *enterprise-led* learning (Department of Enterprise, Trade and Employment, 1997). This was a deliberate contrast to learning driven by State development agencies, hitherto seen as abstract and not meeting the real needs of the industry.

Prior to the establishment of FPN in 2000, skill development initiatives were somewhat haphazard and not systematically applied. Acting on their own, individual firms engaged the services of specialist trainers. The growth of FPN allows firms to combine resources to gain knowledge, achieve economies of scale, acquire technologies and resources and enter new markets. Firms in the learning network gain by increasing their ability to access external expertise thus developing their internal resources and capabilities.

FPN aims to build an *industry-led* sustainable learning network provision for the polymer industry through the development of training programmes leading to Further Education Training and Awards Council (FETAC) certification. (FETAC is a State sponsored accreditation agency ensuring education and training standards).

FPN gives real expression to the principle of partnership at all levels. The requirement for new mechanisms and structures for decision making allows multiple stakeholders to come together in a network-centered learning environment, to co-ordinate and integrate efforts (Baron & Markman, 2000; Blundell & Smith, 2001). Partnerships between key stakeholders widen participation, increase demand for learning and link together measures designed to strengthen local capacity and participation, stimulate innovation, pool resources and develop more flexible and varied provision for learners. Some of the key features of the partnership challenge include:

- Collaboration of employees/firms and collaboration among firms' employees
- Integration of ideas and information
- Capacity to deliver - move fast, take risks, make and learn from mistakes, not afraid of the concept of failure - 'learning by doing'
- Recognition of the workplace as an important opportunity for the achievement of lifelong learning

## **Mould-Tech**

Mould-Tech was established in 1991 as a family business, employing seventy people and specialising in printing of telecommunications components using pad printing/screen printing techniques. In the late 1990's Mould-Tech added injection moulding to its bundle of resources,

enabling it to supply moulded lenses for the mobile phone sector. Four common factors highlight the characteristics of Mould-Tech's path creation strategy as illustrated in Fig. 1.

**Fig. 1. about here**

1. *Displays a single-minded commitment to clearly recognised objectives* - To be at the leading edge of technologies such as in-mould decoration and in-label decoration and continue to improve these existing technologies through modern measurement equipment.
2. *Possesses a focused understanding of the competitive environment* - recognised that it had too great a dependence on the mobile phone sector - in hindsight this was deemed risky. Senior Management saw winning a stake in Ireland's growing medical devices sector as a strategic path for Mould-Tech's future. Significant investment rendered it well positioned to penetrate the attractive medical devices sector, where clean room techniques and moulding precision was already the norm.
3. *Conducts an objective appraisal of resources* - Fulfilling this goal was a challenging task and a key element in Mould-Tech's plan was to bring on board a consultant in moulding technology to develop turnkey cost effective solutions for the medical devices sector.
4. *Affects strategic path solutions* - this is due largely to continuous investment in staff, processes and new technologies. FPN was pivotal in the implementation process by providing *enterprise-led* initiatives in Robotic expertise, Single Minute Exchange of Die (SMED), Design of Experiments (DOE) training and First Line Management skills - all incorporating FETAC qualifications to staff within Mould-Tech. The main motivator for joining FPN has been, inter-organisational collaboration, reducing cycle times, decreasing transaction costs and managing uncertainty through lobbying (Heracleous and Murray, 2001).

**LITERATURE REVIEW**

Following Penrose's (1959) contribution, it is well understood that capabilities are critical to a firm's ability to mobilise and use its resources to grow and compete successfully in rapidly changing technologies and markets (Chandler, 1990; Grant, 2002). In exploring the growth of a firm, Penrose, (1995) was very clear: 'In planning expansion, a firm considers two groups of resources - its own previously acquired or 'inherited' resources, and those it must obtain from the market (in this case FPN) in order to carry out its production and expansion programme'. The implication is that resource configurations develop over time, are constrained by what has gone before and require investment if they are to continue. Penrose asserted that what happened *inside* the firm was just as important as the market place *outside* the firm.

The resource-based analysis (RBA) school of thought attempts to link superior firm performance to capabilities possessed by firms (Teece, 1980; Rumelt, 1984; Wernerfelt, 1984; Barney, 1986; Peteraf, 1993). Although it might at first appear that the RBA is particularly suited to large firms with vast resources, it is also relevant for small and medium-size enterprises (SMEs). Such firms tend to have a smaller number of resources but they can also be more flexible and

entrepreneurial. RBA has been the subject of fundamental criticisms, the most noteworthy of which, relates to the operationalisation of capabilities. For instance, Porter (1994) criticises existing conceptualisations of capabilities for being tautological. The Amit and Schoemaker conception is static, in that it looks at capabilities of a firm at one point in time. As numerous authors have pointed out (Foss, 1997; Teece, Pisano and Shuen, 1997), it is important to go beyond static measures of capabilities and focus on how a firm's superior capabilities might help it in resource creation for the future. This acknowledges the role of path dependencies in the acquisition of capabilities. In the management literature, it is widely acknowledged that leveraging of knowledge throughout firms is important. However, there appears little evidence of what knowledge is transferred between firms and how this occurs. The literature also tends to neglect how firms use knowledge transfer to cultivate appropriate capabilities. Specifically, the author is interested in the following research questions:

- How do learning networks contribute to capability building in small firms?
- How does the learning process take place - including individual and organisational learning, inside the firm and within the learning network?

## **METHODOLOGY**

This research consisted of a single in-depth case study (Hamel, 1993) incorporating a three year observation period, whose purpose was to explore the impact of a Learning Network on path development within Mould-Tech. The study was explanatory in nature. There were many 'how' and 'why' questions to be answered with regard to this issue. It is believed that through direct observation and systematic interviewing, case study methodology was the most valuable for understanding the relationship between a learning network and the capability building process within Mould-Tech. The case study method was deemed appropriate in this context as it sanctioned the investigation of contemporary phenomena within a real life context (Aaker and Day, 1990; Bell, 1993; Yin, 2003) and particularly appropriate to small business research (Hill and McGowan, 1999). This research mode's application is reinforced by Brown and Duguid (1991), who suggest, 'understanding and impacting learning and innovation requires one to study and understand the situation in which practice occurs'. While case research may be criticised for its lack of rigour, the author has followed suggestions from previous studies (e.g. Eisenhardt, 1989; Miles and Huberman, 1994; Yin, 1994) to ensure the validity of the study.

### **Data collection**

Data collection for this study utilised semi-structured interviews in a field setting to ensure standardisation. A case study protocol was designed and used to guide the structured interview and data collection (Yin, 1994). The protocol included multi-diagnostic questions. On site interviews and observations were conducted. While most of the data collection was qualitative in nature, quantitative data was also collected to verify the findings. The use of multiple sources of evidence enhanced both the reliability and validity of the study (Voss et al., 2002; Yin, 1994).

To ensure the quality of the research design several validity tests were conducted as indicated necessary by previous studies (Yin, 1994). Table 1 reviews the tactics applied to ensure the

quality of this case-study method. The rest of this section reviews the information collected in relation to the background of the firm studied and analyses the effects of a Learning Network involvement in its strategic path development.

### **Table 1 about here**

## **FINDINGS**

In a fast-moving, technologically complex and innovative industry Mould-Tech's ability to keep pace with innovation in manufacturing processes forced it to rethink its strategy. Technology within the industry continued to develop incrementally until quite radical changes impacted on the Telecommunications sector - Mould-Tech's key customer base. Argote (1999) observed that any distinct business-specific knowledge or skill may be quickly out-dated or bypassed by shifts in market or stakeholder relationships. While Mould-Tech continually held on to the past, trying to modify its own production techniques with little success, its market share slipped away. What seemed to be a small incremental development in technology required Mould-Tech to totally rethink the way it did business, from its production processes to its sales and marketing strategies! It was unique in its effort to translate its technological understanding of the need for change by re-adapting the routinised processes in the firm. A central challenge facing Mould-Tech is what Volberda (1998) calls the 'paradox of flexibility': 'Organisations need to be able to adapt while remaining stable enough to exploit any changes made'.

Mould-Tech provides technology solutions which involves partnerships with customers, offering services principally centred on component design. This means that Mould-Tech could manage the whole process from initial concept to volume manufacture. Technology road maps provide Mould-Tech with a means of depicting a link between current and emerging technologies that it chose to exploit (Probert & Shehabuddeen, 1999). It outlined the design process, such as sourcing the best components, materials management and final distribution. It involves utilising their global expertise in procurement so that customers can maximise the availability, reliability and flexibility of materials. The emphasis is on lowering cost without losing any quality or speed of operation. Their Materials Resource Planning (MRP) programme provides accurate stock forecasts which facilitates capacity planning and minimises incidences of idle stock.

The firm decided to abandon its traditional functional structure in favour of a more flexible team-based structure and a more business-process-oriented way of doing business. A New Product team was formed offering a wide range of pre-production services. Prototyping is carried out, so that the customer could access the products' suitability for volume production – this has significant savings for the customer in terms of time and money. Before these changes the firm was organized into functions - Production, Administration, Purchasing and Marketing/Sales. This structure created problems with cross-functional co-ordination. In the new structure teams reported directly to the senior management team. The responsibility for co-ordination of any project was shared between the business team (commercial responsibility) and delivery team (production planning).

The paths traveled give Mould-Tech significant advantages:

- *First-mover advantage* – by being the first to make a strategic move in the market they have the capability to launch a new product ahead of the competition. On the face of it,

this gives considerable benefits. It takes time for competitors to catch up, allowing Mould-Tech to gain economies of scale, experience curve effects, build customer loyalty and therefore enjoy switching costs. Their strategic path initiatives enable them to use technical know-how and build a market stronghold in the medical devices sector as resource-based competitive advantages.

- *Core capabilities that it deems robust in nature* – are embedded in the way the firm works and not explicit. For example, higher levels of personal service, specialist expertise, design skills and bespoke solutions. This may be regarded as organizational knowledge, based on intuition and experience i.e. shared knowledge based on interactions across many parts of the firm - ‘ways of doing things’

## CONCLUSION

There is much anecdotal evidence that a scarcity of resources encourages learning. Unlimited resources breed waste and inefficiency. Innovation, invention and adaptation are encouraged in an environment of shortage, competition and the struggle for survival. Using the SWOT model, the absence of *threat* removes the stimulus to exploit all the firm’s *strengths*.

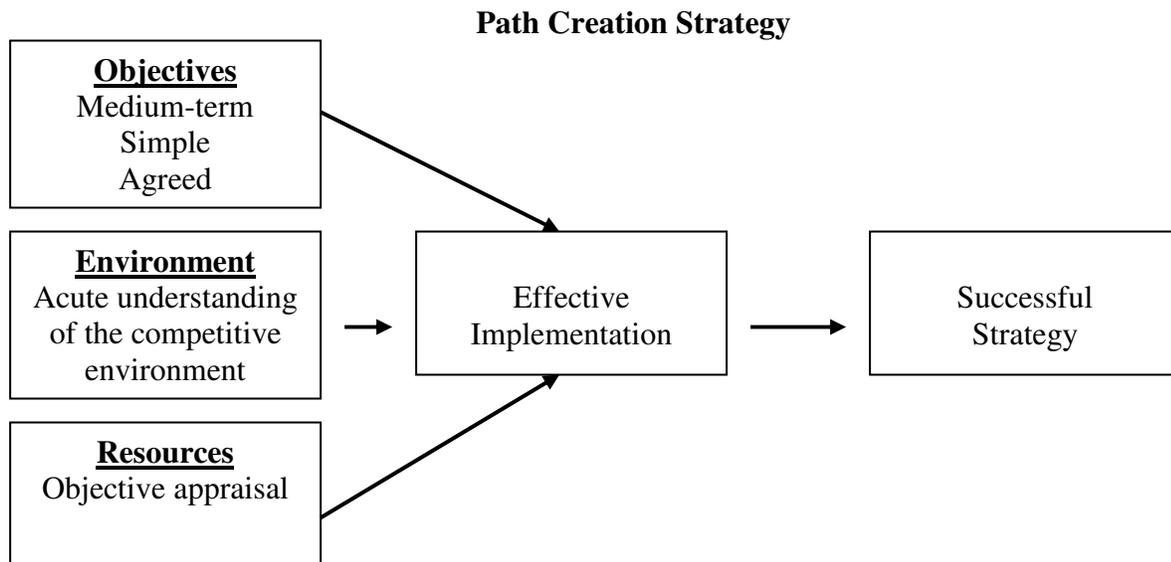

Small firms such as Mould-Tech are only too aware of the external environment in which they operate (Threats and Opportunities). They know that complaining about what is a globalised marketplace is a waste of time. So they work on developing their strengths (capabilities) - speed of adaptation etc., recognising their weaknesses - high wage costs etc. and reacting to the external environment.

In the context of this paper, it is clear that Mould-Tech knows that it must meet increasingly arduous production standards to remain in business. The industry standard approach is to purchase modern equipment designed for these tight tolerances. However, Mould-Tech can not justify the expenditure and must seek other means of meeting standards. As a consequence, it modifies its processes and procedures to meet exacting standards. This has led to discovering new ways of setting up existing machines, preparing feed materials and monitoring performance. These skills have become available across a range of its activities and produce an improved all round performance. It has developed a new set of capabilities which enhance its ability to compete and more importantly, its ability to learn how to compete. None of this would be possible if it had not participated in the learning network - FPN.

Capability building through participation in FPN is deemed more likely to be successful in Mould-Tech as it builds on the strengths already available to it, rather than starting from scratch in a totally new area. Building on this prior knowledge confers an ability to recognise the value of new knowledge and assimilate it. Cohen and Levinthal (1990) refer to this ability as absorptive capacity. Management recognises that this does not guarantee that the strategy will be successful but it is a contributing factor. Building on existing strengths, exploits uniqueness that has been built as a result of the firm’s history and investment over the years - path dependency. New capabilities do not mystically appear within the firm - they are the outcome of deliberate learning processes, as Winter (2000) has stressed: ‘To create a significant new capability, an organisation must typically make a set of specific and highly complementary investments in tangible assets, in

process development and in the establishment of relationships that cross the boundaries of the organisational unit in which the process is deemed to reside’.

Mould-Tech is an example of a small manufacturing firm that has realised new capabilities through the shared expertise of partner organisations in FPN. This study has highlighted the movement of an Irish SME in the polymer industry towards a new business paradigm involving the exploitation of shared expertise in a learning network. The ‘*learn and earn*’ paradigm of strategic partnership as exemplified in this study is serving to foster a newly strengthened industrial sector in Ireland.

## ABSTRACT

Corporate narrative is a term describing the use of narrative in organizations. Interest in corporate narrative has grown out of the increasing acceptance of interpretivism as a research tool, the growing use of case studies in management research and growing understanding of the importance of narrative in field studies. As management researchers begin to utilize the study of corporate narrative as a research tool, it behooves us to begin a discussion of the role that the researcher plays in actually developing these narratives.

This paper examines the role that the researcher played in the creation of corporate narrative in a three year old service company in the natural gas industry between 2003 and 2004. The primary role of the researcher in field study was found to be the role of sounding board for the interviewed. An important secondary role for the researcher was found to be the role of mediator who draws societal meaning out of the narrative.

This study points out both the power and the limitations of active researcher involvement in qualitative research. The power of active researcher involvement in qualitative research comes from the ability of the researcher to experiment with the implementation of theoretical speculation in the fieldwork setting. The limitation of active researcher involvement in qualitative research comes from the bias that the researcher introduces into the fieldwork setting.

## INTRODUCTION

While there is not general agreement as to what the term *narrative* means, it is generally conceded that the term refers to a thematic, sequenced account that conveys meaning from an author to an audience (Barry & Elmes, 1997, p.431). Scholes has described narrative as: "...the symbolic presentation of a sequence of events connected by subject matter and related by time" (Scholes, 1981, p.205). Ricoeur has defined narrative as "the discourse of a narrator recounting the discourse of the characters" (Ricoeur, 1984). Implied in both definitions is the attempt by individuals to create meaning of both past actions and new sequences of events. Currie suggests that narrative is an essential part of the human condition; we define ourselves as the tellers and interpreters of narrative (Currie, 1998, p.2).

Corporate narrative (Fleming, 2001), or organizational narrative (Boyce, 1996), are terms describing the use of narrative in organizations. Corporate narrative can take the form of a performance (the act of narration) or the form of text (the written account of a narrative) (Boje, 1991, p.110). Corporate narrative can be fiction or non-fiction. Boje has described how the Walt Disney Company used fictional narrative to craft an official history that ignored the darker side of Walt Disney and the Disney corporate culture (Boje, 1995). Alvarez and Merchan have described the common use of narrative non-fiction in management education, in the form of case studies (Alvarez & Merchan, 1992, p.29).

Gabriel suggests that corporate narrative is a growing field of study (Gabriel, 2000, pp.17-18). Interest in corporate narrative has grown out of the increasing acceptance of interpretivism as a research tool (Hiley *et al.*, 1991), the growing use of case studies in management research (Gummeson, 2000, p.3; Remenyi *et al.*, 1998, p.165) and growing understanding of the importance of narrative in field studies (Bruner, 1986; Pentland, 1999). Qualitative researchers are discovering that open-ended interviews allow them insight into many areas of management, which are not ordinarily on view. Corporate narratives can expose interpersonal issues, such as racism or sexism in the workplace, can shed new light on old

problems, such as the working of corporate culture and can help researchers understand working situations such as job-related stress and trust (Rubin & Rubin, 2005, pp.2-4).

As management researchers begin to utilize the study of corporate narrative as a research tool, it behooves us to begin a discussion of the role that the researcher plays in actually developing these narratives. This paper examines the role that the researcher played in the creation of corporate narrative in a three year old service company in the natural gas industry between 2003 and 2004. The analysis is structured around two axes: the role of the researcher as an agent of the creation of the corporate narrative and the role of the researcher in the institutionalization of the meaning of the corporate narrative.

## LITERATURE REVIEW

Becker and Geer were early qualitative researchers who realized that a specific advantage of participant observation is the completeness of information provided to the researcher (Becker & Geer, 1970, p.133). However, as Ruben and Ruben have pointed out, the researcher must recognize the part that he or she plays in creating the construction of this information (Rubin & Rubin, 2005, p.30).

Kvale has conceptualized the role of the researcher in narrative study through two metaphors: the metaphor of the researcher as a traveler and the metaphor of the researcher as a miner (Kvale, 1996, p.3). The metaphor of the researcher as traveler depicts the researcher as a reporter, who constructs meaning through the agency of conversation. The metaphor of the researcher as miner depicts the researcher as a discoverer who mines precious facts and meaning as the agent of institutionalism of knowledge. These two roles mirror two important forms of qualitative discovery: action research and institutional ethnography.

Action research traces its origins to Aristotle's definition of *praxis* or practical knowledge (Eikeland, 2001, pp.146-149). Recent pioneering of action research is credited to Kurt Lewin (Lewin, 1946) and Chris Argyris (Argyris *et al.*, 1985). Reason and Bradbury define action research as:

A participatory, democratic process concerned with developing practical knowing in the pursuit of worthwhile human purposes, grounded in a participatory worldview...It seeks to bring together action and reflection, theory and practice in participation with others, in the pursuit of practical solutions to issues of pressing concern to people, and more generally the flourishing of individual persons and their communities. (Reason & Bradbury, 2001, p.1)

In action research, the researcher acts as a reporter, who through the agency of conversation constructs meaning. Gummesson has noted that action research affords scholars the opportunity to couple the demands of consultancy work with the demands of academic research (Gummesson, 2000, pp.210-218). A common goal of the action researcher is to assist stakeholders in describing their work or organization in detail (Stringer, 1999, p.65). In moving towards this goal, the researcher often utilizes and develops corporate narrative. However, it has been pointed out that is important for the researcher to be aware of his or her intervention in the research situation and in the development of the resulting narrative (Remenyi *et al.*, 1998, p.49). Wadsworth also notes that action research involves all parties in actively examining their current actions (Wadsworth, 1998, p.13).

Institutional ethnography traces its origins to the development of ethnomethodology as a tool of social inquiry by Harold Garfinkel (Garfinkel, 1967). Smith, through her work as a feminist sociologist, has defined institutional ethnography as:

...an insistence on discovering and writing the social as the everyday and every night coordinating of people's actual activities...as participants in discourse entering into and contributing to forces that stand over against us and overpower our lives (Smith, 1999, p.228)

In institutional ethnography, the researcher acts as the agent of institutionalism, pointing out the linkages amongst the narratives of everyday life and the implications for organization, administration and governance (DeVault & McCoy, 2003, p.369). A common goal of the institutional ethnographer is turning narrative into text. Through the development of a case study, many of the social relations embedded in narrative are explicitly recognized. Smith has noted that part of this process involves creating a sense of accountability between what members of an organization actually do and what these members interpret their actions to be (Smith, 1987, p.161).

## FIELDWORK

This study draws upon field research conducted in 2003 and 2004. This field research captured seven hours of oral narrative performed by the senior management of a three year old service company in the natural gas industry, CJB Ventures Ltd. The recordings were made in two sessions, May 7<sup>th</sup>, 2003 and July 17, 2004 and involve the researcher in dialogue with the company principals: Cam McKenzie, Jim Fjeldsted and Bruce Henderson. Each of the company's principals has spent years working in the harsh conditions of Canada's Western Sedimentary Basin and each is an accomplished story-teller.

The first recording session, May 7<sup>th</sup>, 2003 was intended as a strategic planning retreat. The narratives recount the start-up and rapid growth of the business and describe a number of issues that the company has had to face in its early years. As a result of this discussion with the researcher, the principals of the company made a decision to abandon their efforts to establish a reclamation venture, CJB Reclamations Ltd. and to concentrate their effort on the more profitable inspection and supervision of gas pipeline installations.

The researcher interpreted key elements of the narratives recorded in this session into a written case study: Harvesting CJB (McKenzie, 2004b). This case study summarizes the narratives of the principals of the company and describes the impressive financial results of their decision to concentrate their efforts in the inspection and supervision of gas pipeline installations. The company grew from a profit of approximately \$10,000 in 2003 to a profit of \$300,000 in 2004. The case study, Harvesting CJB ends with a description of the next problem facing Cam, Jim and Bruce: how should they harvest the value from their venture?

The researcher created a second interpretation of the narratives in a formal evaluation of the value of the venture (McKenzie, 2004a). This valuation was presented to the management team at the beginning of the second recording session. The narratives of second recording session, July 17, 2004, revolved around each of the principal's vision of the future of CJB Ventures as well as an exchange of stories of recent fieldwork experiences.

Four weeks after the second recording session, one of the principals had a disagreement with a major client. This disagreement led to a serious dispute amongst the three principals of

the company over the way that the client had been treated. The dispute was resolved by two of the partners buying out the third partner.

## DISCUSSION

The primary role of the researcher in field study is to act as a sounding board for the interviewed. In this position, the researcher must acknowledge his or her role as an agent of the creation of a corporate narrative. In this study, the researcher set the stage for the development of corporate narrative by bringing the principals of CJB Ventures together to discuss the past and future direction of the company. The researcher acted as the author of this corporate narrative both in scripting the pattern of individual narratives and in developing these narratives into a cohesive text. This role would appear to embody the principles of institutional ethnography.

An important secondary role for the researcher is to act as the mediator who draws societal meaning out of the narrative. Thus, while the narrator claims authorship of his or her story, the interviewer claims authorship of what Edward Bruner describes as “the three tellings of fieldwork” (Bruner, 1986, p.147). The first of these tellings is the direction of the memoirist’s recollection by telling what information the interviewer is seeking. The second telling is the part the interviewer plays in the creation of the narrative: both as a listener and as a questioner. The third telling is the summary and analysis the interviewer creates for the audience of his or her scholarly work. This role would appear to embody the principles of action research.

It would appear that the disagreement between the one partner and the major client was recognized by the other partners as being dissonant to the corporate narrative generated during the two recording sessions. This partner had engaged in similar disagreements previously and none of these disagreements had led to dispute amongst the partners. It would appear that the development of institutional norms through the evolution of corporate narrative allowed the other two partners to recognize the transgression of these norms.

## IMPLICATIONS

This study has important implications for both researchers and practitioners in the field of entrepreneurship. The study points out both the power and the limitations of active researcher involvement in qualitative research. The power of active researcher involvement in qualitative research comes from the ability of the researcher to experiment with the implementation of theoretical speculation in the fieldwork setting. The limitation of active researcher involvement in qualitative research comes from the bias that the researcher introduces into the fieldwork setting.

As pointed out in the discussion, the mere presence of the researcher changes the direction of corporate narrative by creating an audience for the performance of the narrative. The researcher further influences the creation of corporate narrative by controlling the agenda of the discourse that creates the narrative. This effect is compounded, when the development of the corporate narrative creates a new institutional framework which is used by the actors of the narrative to measure the relationship between their own and each other’s personal narratives and the corporate narrative.

Researchers will be able to use this study to assist in the determination of the effects of researcher bias in qualitative studies. The subtle nature of the influence of the researcher in the development of corporate narrative requires sensitivity to this influence. Action researchers

should be aware that there is often a conflict between their role as consultant and their role as researcher. Institutional ethnographers should be aware of the recursive nature of the development of social relationships embedded in corporate narrative.

Consultants will be able to use this study as a guideline for the effective collection and analysis of corporate narrative. Techniques described in this paper outline the powerful role that corporate narrative can play both as a normative and a prescriptive tool.

**SMALL BUSINESS BENEFITS, AS BLACK ECONOMIC EMPOWERMENT DRIVES THE SOUTH AFRICAN ECONOMIC MIRACLE**

**SMALL/BIG BUSINESS PARTNERSHIPS - LESSONS FOR BUSINESSES EVERYWHERE ARE BEING LEARNT IN THE ECONOMIC REVOLUTION CURRENTLY UNDERWAY IN SOUTH AFRICA.**

Ivan van der Merwe

SAESBA, South Africa

South Africa is intent on producing an economic miracle comparable to its political miracle of 1994. That process is now underway, although still in its early stages. The main method for fast-tracking the empowerment of previously disadvantaged persons is through employing established businesses to share their existing business knowledge, risks, assets and opportunities - and transferring skills. In the South African model this transfer process is between larger (white) businesses and smaller (black) businesses, but in any country similar programmes can be developed between larger and smaller businesses, irrespective of race. The challenge is to motivate larger businesses to see this as being in their own interest.

**Introduction**

The South African political miracle happened 11 years ago, in 1994. That event transformed the political scene in the country. The economic transformation that needed to follow could, however, not be achieved on one election day and hesitant steps were taken during the first 10 years of the new democracy, mainly by big businesses, to bring black persons in as participants in ownership and management.

The slow pace of economic transformation is evident in the 2003 earnings estimate which shows that 95% of all persons earning executive level incomes of US\$60,000 or more per annum – are white persons. In the absence of hard statistics it can be extrapolated that business ownership proportions would be similar.

This led to the introduction, during 1998 to 2003, of strong encouragement measures, mainly through preferential procurement systems, inducing many businesses to start changing their ownership profiles as well as employment policies, procurement policies, etc.

**NEW SYNERGIES BETWEEN “EMERGING” AND “ESTABLISHED” BUSINESSES**

While working as a small business strategy consultant, I noticed the potential for synergies between black and white businesses. On the one hand a typical small, black-owned, business finds itself with a growing potential to capture certain markets, yet often lacking the capacity to deliver to required standards or quantities. These markets mostly consist of government and corporate procurement opportunities, but also export and local consumer markets.

On the other hand, many white owned businesses have excess capacity and need to expand their markets or recapture lost markets.

This presents a unique opportunity for the creation of synergies through matching and joining the interests of these two business types. The benefits for the promotion of the policy of black economic empowerment are obvious.

For historical and cultural reasons black and white small business owners do not tend to meet each other very often, and this means that promoting these synergistic partnerships needed a catalyst.

The City of Cape Town provided funding in 2003 for an internet based database system to find and link potential partners countrywide for such joint venture businesses. Businesses that are not yet linked to the internet can join the system by telephone or personally. Once a link is made, further services are provided to assist the dealmaking process.

Benefits of these new joint ventures have become clear, and these include:

- The expected synergies often do take place, benefiting both partners, in some cases quite spectacularly. One example is that of a factory owned by a black family that experienced severe difficulties with working capital and management despite having access to scarce raw materials. A white business was introduced and took a minority shareholding. New technology was introduced and a finance provider then agreed to provide working capital. Management training followed, and the business was turned around and ready for strong growth;
- Real empowerment takes place through ownership of business assets, senior management roles for black persons, and the development of latent entrepreneurial and business leadership talent;
- The willingness of both racial groups to do business together is exceeding expectations and bodes well for the future growth and stability of the South African economy.

So far, this is just a short overview of some aspects of the Black Economic Empowerment (BEE) process as it applies to small businesses. As can be expected in any transformation process, it is not all smooth sailing. All the difficulties, inequities and abuses of the process as well as the formal process itself are certainly worthy of debate and criticism and one is tempted to get into that debate right now.

But I have another debate to propose to you. One that is more relevant to this forum as a whole, although some of the thinking behind this proposal derives from the black empowerment process in South Africa.

## **ENTERPRISE DEVELOPMENT AS BUSINESS POLICY**

In terms of the BEE process, industry-wide black economic empowerment policies have been adopted by major industries in South Africa providing, inter alia, for expenditure on “enterprise development”, i.e. larger companies contributing to the development of smaller businesses. In world terms, this could well be a unique business policy item. Never before have the bigger and medium sized businesses adopted policies and budgets intended to support and develop other businesses. This new practice is certain to have far reaching effects for small business development.

Many of these larger companies are likely to focus on developing their own suppliers. A new skill set now needs to be developed or contracted by the larger companies – that of small business development advisors and mentors.

### **APPLICATION IN OTHER COUNTRIES**

The question now is: Would larger companies in other countries be prepared to adopt similar policies? This of course depends on whether they see it as being in their own best interests.

There are three possible approaches towards providing motivation for this process:

- Long range macro planning;
- Government incentives; and
- Corporate supplier relationships (CSR)

### **Long range macro planning**

The strength of the economy of a country is usually measured in terms of the flow of money, goods and services, but the underlying basis of that strength is the human entrepreneurial effort that produces business growth. Stated more specifically, the number of competent business and entrepreneurial leaders in a country, relative to its population, is a major determinant of its economic growth.

In the previous political era South Africa was drawing its business leaders & entrepreneurs mainly from a section comprising about 12% of the population. This suggests that South Africa should, over time, be able to multiply its pool of competent business leaders. My own target would be for at least a four-fold growth. This is bound to lead to a substantial increase in the performance of the economy.

South Africa aims to develop these new business leaders through a process of *sharing* existing business knowledge, risks, assets and opportunities - and transferring skills. In the South African model this transfer process is between larger (white) businesses and smaller (black) businesses, but in any country similar programmes can be developed between larger and smaller businesses, irrespective of race. The challenge is to motivate larger businesses to see this as being in their own interest.

### **Government incentives**

Most governments understand very well the crucial contributions made by small business enterprises to the economies of countries and especially to job creation.

In most countries access to academic institutions for small business owners to develop their skills as entrepreneurs and business managers is woefully inadequate. Even in countries where such access can be regarded as adequate, there remains the need for development of practical skills.

The knowledge and skills base contained within the more substantial and established corporations is vast, and if that resource can be employed in the development of small enterprises, it can lead to strong growth for the small business sector.

Governments could therefore provide tax incentives or other inducements to corporations in exchange for the provision of training, mentoring and support to smaller businesses.

### **Corporate supplier relationships (CSR)**

Business corporations have two groups of people participating in the production of their market offerings, i.e. their full time staff and their suppliers. Staff and suppliers have several things in common: Both groups consist of people; both provide services to the employer; both have an interest in the success of the employer; and, the services of both require integration into the final offering of the employer. Yet, employer companies treat these two groups very differently.

The Business Link Service in the UK runs a "Benchmark Index" service. It is essentially a best practice benchmarking service. Their criteria for staff include 20 best practice standards while only four criteria refer to suppliers.

In the Malaysian MITI Annual Report on Small Enterprises in 1984, it was stated that "the Japanese manufacturing industry owes its competitive advantage and strength to its subcontracting structure".

Professor John Carlisle of the Centre for Integral Excellence at Sheffield Hallam University in the UK quotes these further examples:

British Leyland had a terrible relationship with their suppliers even as late as the early 1980s. One of the results was that in one month they had to return over 22,000 defective parts to their suppliers - a real lose/lose.

The tragedy of the tenth Challenger mission: a direct consequence of the buyer (NASA) riding rough-shod over its supplier.

The Xerox and Honda stories are becoming legendary, as is Motorola because buyer/supplier partnerships have been an integral part of their Total Quality drives from the beginning.

Chrysler, with its annual savings of \$1.5 billion from its suppliers, is probably the success story of the west.

We have benchmarks that corporations aim at, such as “to have an employee satisfaction ratio of 73%”. Do any of these corporations have a benchmark for a “supplier satisfaction ratio”? We even have ratings for “Best company to work for” – BUT only for employees. What about doing the same for suppliers?

Most manufacturers spend around 60% of their money on the supplies that are necessary to keep the business running. This is an indication of the relative importance of supplier relationships.

Here are some ideas towards building a best practice model for corporate supplier relationship (CSR) management:

1. Establish a formal CSR programme and produce an annual written CSR report that includes a review of support provided to suppliers.
2. Identify key suppliers with whom you form a closer working relationship, which involves some joint working. Establish formal ‘partnerships’ with them and share knowledge with them to improve the way each of you works and adds value to your customers.
3. Involve your suppliers in developing new products and services.
4. Build a relationship of trust with suppliers.
5. Recognise individuals or teams of suppliers for loyalty or contributions to the business.
6. Commit at least 3 percent of total procurement spend for investing in CSR. (This percentage is an attempt to align with international best practice for skills development expenditure on staff at 6% to 8% of payroll in appropriate industries.)
7. Carefully evaluate potential suppliers and their backgrounds in order to select the suppliers that will best fit the needs of the business.
8. Engage suppliers in forward planning. This is critical in establishing the stability in the supplier relationship that is necessary for both parties to feel comfortable. Furthermore, the future planning makes it more likely that the supplier will have the resources and qualified staff available when the buying company requires them.
9. In addition to focusing on the direct service provided by the supplier, provide deliberate contributions to the general development of the supplier business.
10. Assign day-to-day management responsibility for CSR to a position that is no more than one executive away from the CEO or COO.

**PROPOSED INTERNATIONAL COLLABORATIVE TEAM**

I want to end with a proposal for this conference, namely that the ICSB put together an international collaborative team on Corporate Supplier Relationships (CSR) with the following objectives:

1. To formulate an international best practice model for CSR.
2. To find (or establish) and promote a CSR information/training programme for employer companies.
3. To research existing and proposed effects of effective CSR practices on small business development and employer company benefits.
4. To research and lobby governments to provide incentives and/or assistance to employer companies towards improved CSR practices.

I would like to invite all delegates and others who may be interested in participating in this proposed team to contact me and I will take it up with the ICSB board.

# **BUILDING MECHANISMS FOR NURTURING INNOVATIVE SMEs: *Lessons from the North American Science Parks and Incubators***

## **Introduction**

It is now widely accepted that knowledge and innovation are engines of economic growth and that innovative small and medium sized enterprises (SMEs) are key contributors to that growth. Like the other vibrant regions of the world, countries of the North American Free Trade Agreement (NAFTA) region (US, Canada, and Mexico) are focusing on the development of their knowledge-based economies. This requires policies that are placing an ever-increasing emphasis on the successful development of new technologies and their commercialization through SMEs. As the NAFTA embarks on its second decade and we build on the accomplishments of its first ten years (1994-2004), it is an opportune moment to assess the effectiveness of the mechanisms employed to support the development of innovative SMEs in the North American region.

As policy makers at various levels of government grapple with strategies to stimulate the development of innovative SMEs in their regions, they consider various enterprise development tools available in the form of direct incubation mechanisms, to realize their future economic development objectives. In North America, science parks and incubators are the main mechanisms that have been employed over the past 25 years for providing enabling “incubation spaces” for the creation and growth of SMEs. The technology business incubation concept holds

out the possibility of linking technology, know-how, entrepreneurial talent and capital (Mian 1996, Smilor, and Gill 1986). Science parks and incubators are generally established through collaboration among university, industry and government, and are aimed at promoting technology diffusion into the local economy (Etzkowitz 2002). Most North American technology incubation facilities are directly or indirectly associated with universities — the primary source of trained human and intellectual capital — or with public or private research laboratories, and share common objectives such as providing a training ground for entrepreneurs and supporting technology-led entrepreneurship based on university or laboratory research results. Many of these incubation mechanisms are sponsored in full or in part by universities, colleges or research laboratories. Other sponsoring organizations include state and local economic development agencies as well as private parties (Doutriaux 2001).

After providing an overview of the evolution of technology business incubation industry, this paper examines 12 regional cases from across North America<sup>2</sup>. For each of the three NAFTA nations four regional cases with science park and incubator mechanisms were selected for in-depth study. Unlike in the US and Canada where both science park and incubator industries have taken roots, the Mexican cases emphasize more on incubators due to the limited science park experience of the nation. Background information is provided for each case. It is followed by an assessment of the performance of these mechanisms. The article concludes with a synthesis of the case studies, and a list of the “best practices” and lessons that seem to be most appropriate for various types of regions along with policy implications.

## **Mechanisms for nurturing SMEs:**

### **Science parks, incubators and their evolution**

The modern organizational mechanisms employed for supporting the creation and growth of technology-based firms (TBFs) are known under various names – science/research/technology parks, technology incubators, innovation centres, and technology centres. The underlying common function of these mechanisms is the provision of a tangible physical space for TBFs in proximity with other public and private support organizations that allows networking opportunities and facilitates the acquisition of value added services. However, in recent years (late 1980s) the popularization of the concept of virtual incubators in which networked regions act as “incubation spaces” and “distributed parks” has made the provision of physical space somewhat optional, making the intangible component of the value-added support services for TBF as key characteristic of some of today’s incubation programs.

The main differences between traditional science parks (generally called research parks or technology parks in North America) and technology incubators (often called innovation centers in Europe) are that<sup>3</sup>:

The parks are property-based ventures consisting of research and development facilities for technology- and science-based companies. They often promote community economic development and technology transfer. They tend to be larger-scale projects than business incubators, often spanning many acres or miles. The parks house everything from corporate, government, and university labs to big and small companies. Unlike business

incubators, the parks (particularly in North America) do not generally offer comprehensive programs of business assistance. However, an important component of some university parks is a technology incubator focused on early-stage companies. On the other hand, technology incubators have main objective of nurturing the development of entrepreneurial companies, helping them survive and grow during the start-up period, when they are most vulnerable. These programs provide their client companies with technology and business support services and resources tailored to young firms.

According to the Association of University Research Parks (AURP)<sup>4</sup> there were more than four hundred (411) science and technology parks worldwide in 2002 out of which 41 percent (167) were in North America – with roughly 86 percent (144) in the US and the rest in Canada and Mexico. Another end of 2002 survey by Association Research Inc. identified 179 park facilities in the US and Canada<sup>5</sup>. According to the survey, these North American parks (49 percent response rate) revealed that a majority of them (70 percent) were established with the help of public funds and most (83 percent) were incorporated as non-profit entities. Average size of the parks surveyed was 532 acres (3 to 7000 acres range) housing 41 firms and related-organizations and employing 3400 persons per park. The average capital investment was US\$186 million per park. The report revealed that 62 percent of the responding parks have incubators. The dominant technologies (many parks reported more than one technology) were medical biotechnology followed by information technology. A 2004 estimate put the number of North American parks to 194, reporting park facilities in 40 US states<sup>6</sup>. A Coopers and Lybrand study had found a growing trend towards establishing incubators in both existing and new parks<sup>7</sup>. Another survey of park managers had revealed that in the US, 88 percent of the parks have access to university

resources, more than half of these parks are estimated to be growing in terms of buildings and tenant facilities and another less than one third are thought to be stagnant<sup>8</sup>. Figure 1 graphically displays the growth of the North American science parks industry since the 1960's. The graph demonstrates the drastic increase in the establishment of parks in the mid-1980s to the early 1990s.

---

Figure 1 about here

---

According to NBIA<sup>9</sup>, as of 2004 there were more than 4000 incubators worldwide out of which 1000 business incubators were spread all across North America (including 5 to 6 percent in Canada and Mexico combined). In 2002, around 950 North American incubators were occupying an average of 47,000 square feet of space and had 22 client firms per facility. They were serving more than 35,000 startup companies and providing full-time employment for 82,000 people<sup>10</sup>. Approximately 37 percent of these incubators (around 350) are technology-related, up from 25 percent in 1998; a quarter of which are university or college affiliated<sup>11</sup>.

Statistics on the number of incubator facilities over time shows a trend similar to that of science parks (Figure 2). However, the science parks were around a bit longer than the incubators. The

---

Figure 2 about here

---

literature on this industry follows also a similar trend, most of the literature having been generated in the 1980's. Recent studies do show that both science parks and incubators continue to be developed, however cautiously<sup>12</sup>. The industry temporarily paused in the early 1990's as researchers, policy makers, and park & incubator managers focused on improving the effectiveness of existing facilities rather than on establishing new ones. In the early 2000's, growth has resumed as shown by the large recent increases in the number of incubators.

In the late 1990s, a large numbers of experienced investors/company builders started engaging in formal business incubation through the creation of new models of incubation – internet incubators, accelerators, eggubators, virtual (portal) /hub incubators, networked incubators, internet Keiretsus/ Zaibatsus, captive (corporate) incubators, business and technology accelerators. This interest in for-profit business incubation occurred so rapidly that within a matter of months the percentage of North American incubators represented by this category exploded from only 10 to 12 percent in 1998 to more than 35 percent by the late 1999/early 2000. When the NASDAQ market for technology and internet stocks plummeted in April 2000, a large number of these internet incubators and their clients firms started to fail. It is estimated that by 2002, they had fallen back to their 1998 levels. Some facilities have survived until 2004-05 the volatility of the stock market, but it remains to be seen whether this new type of incubation mechanisms will be sustainable over the long-term (Lavrow, Sample 2000). However, as evidenced by their continued popularity and growth, the impact of the market volatility on the traditional brick and mortar not-for-profit incubators has thus far been limited.

In summary, within the past quarter of a century since the concept of business incubation through science parks and incubators first began to take root in the United States, the industry has grown rapidly and matured considerably. The hey-day of this industry came into being during the last two decades of the past century in which it survived growth spurts so explosive that both public and private entities often engaged in a great deal of ill considered and poorly planned incubation development initiatives. The industry also survived economic down turns, and the sometime unrealistic expectations of government funding agencies and economic developers. Given the complexity of developing such business and technology support programs for new innovative ventures, business incubators needed time — the time to test, to experiment and adapt, and to fail or succeed. Years ago it was often said that it would take 10 to 20 years for the true value of incubation industry to make itself known. Luckily, in the US, that time was afforded. In future, given the generally positive experience of the last two and a half decades as a guide, it may well be that every community that aspires to follow suit will learn from this unique experience.

## **Benchmarking the Incubation Mechanisms:**

### **Learning from the Best Practices**

Dedicated incubation spaces, generally science parks and technology incubators, are used as basic enterprise development mechanisms in many technology innovation poles. It is therefore essential to evaluate the efficiency and effectiveness of those spaces and related programs (the incubation system) as elements of any regional technology incubation strategy. Despite the steady increase in the number of these relatively new technology innovation mechanisms since

the early 1980's, especially in North America<sup>13</sup>, there has been no single framework available to assess how they are working and thereby improve their effectiveness. As noted by Autio and Klofsten (1998), "in spite of the rapid increase in the number of evaluations, the available material is largely dominated by documents of the so called "success story" type." This has placed economic development leaders in a difficult position. On the one hand the regions that see a wave of activity sweeping the world feel some pressure to follow suit. On the other hand, experts caution that the jury is still out due to the lack of pertinent experience and hence evidence about their usefulness (Mian 1997). This is particularly true in light of the numerous questions regarding their impact and organizational self-sustainability. In the case of business incubation, the challenges confronting researchers developing such a framework include (Doutriaux 2001):

- Lack of understanding of the technology business incubation process;
- Lack of consensus on the type of evaluation criteria to be used (OECD, 1997, page 24);
- High heterogeneity of the population of science parks and technology incubators, with a high variety of sponsors, objectives, science orientation and business models;
- Lack of proper experimental design with an appropriate control group to correct for pre-incubation firm characteristics and external effects (Sherman and Chappel, 1998); and
- Short times series of data for analysis because of the emerging nature and relatively short history of these mechanisms.

Success is relative and depends on expected outcomes. As noted by Bearse (1998), "The definition of a business incubator in terms of its goals and objectives provides the essential

starting point for an evaluation”. However, not all incubation programs have the same goals and objectives. Whereas an economic development agency may be interested mainly in job creation, a university may look for dynamic research linkages and research funding, whereas a for-profit incubator may insist on profitability and return on investment. Success criteria will therefore generally differ from case to case, making for difficult comparisons and generalizations.

Sherman, Hugh and David Chappell (1998), have proposed four domains of potential incubator impact, each needing their own sets of measurements: “incubator-level impacts, firm-level impacts, community-level impacts, and ancillary community impacts”. Studies on “best practices” often use the following criteria: number of jobs created (by tenants and by graduates, locally and globally), number of graduates and survival rate, sales of tenant firms and of graduates (locally and globally), growth in sales and profitability of tenant firms, number of clients served and their geographic distribution, incubator revenue (profitability, sustainability), new technologies brought to market, taxes paid by the incubator and its tenants, local economic impact (direct and indirect impact, in terms of business activity, jobs, regional exports and imports, property values).<sup>14</sup>

The most important weakness of most assessment schemes is the difficulty to find an acceptable control group to evaluate the impact of the incubation program (incubator, science park) itself and control for the new firms’ individual dynamics (start-up characteristics, management team, business proposition), technology life cycle, sector of activity, external economic and technological factors: how different would have those firms’ development be if they had not joined the incubation program?

Typical key success factors reported in the literature and by practitioners include:

- a well researched business plan/feasibility analysis with focus on financial feasibility, sustainability
- a business management approach, with enough financial resources to hire an experienced incubation program manager and to offer competitive staff salaries.
- local business community support, local businesses having recognized the need to broaden/diversify the local economy
- local government ready to champion the concept and acting as stimulator, strategic partner
- partnerships with local universities or colleges
- strategic partnership between all levels of governments
- proactive board of directors with vision and good business/social networks

To benchmark the performance of an incubation mechanism — technology incubator or science park — a comprehensive assessment framework is proposed, which is based on the following three key sets of variables<sup>15</sup>:

(1) *Performance Outcomes* - the incubation system's performance outcomes are assessed using four elements: (a) program sustainability and growth; (b) tenant firms' survival and growth; (c) contribution to the sponsors' mission; (d) community-related impacts.

(2) *Management Policies and Their Effectiveness* - an assessment of the incubators and science parks' management practices and operational policies in light of the program objectives provides a review of the effective utilization of resources resulting in the success of the program. The key elements assessed include: (a) goals, organizational structure and governance; (b) financing and capitalization; (c) operational policies; (d) target markets.

(3) *Services and Their Value-Added* - a review of the actual provision and their perceived value-added to the client firms in the form of: (a) the typical shared office services including rental space and other business assistance services; (b) the sponsor institution -related inputs, such as, in the case of a university, student employees, faculty consultants, and other institutional support and provision of networking for the TBF.

## **North American Case Studies**

This section will present twelve case studies from emerging technology regions in North America in which science park and incubator mechanisms have played varying roles. The purpose is to identify “best practices” in various environments that could eventually be considered, after some adjustments, for building such mechanisms to help develop regional innovation capacity through appropriate public policy measures.

## *The US Cases*

The US is a leader among NAFTA nations in terms of experience with science parks and incubators. The following paragraphs highlight the role these incubation mechanisms have played in the transformation of four US regions into emerging technology innovation poles. The park and incubator facilities analyzed in these regions are: Rensselaer Technology Park and its Incubator Program in the New York Capital Region; Northwestern University Evanston Research Park and its Innovation Center in the Chicago Metro Area of Illinois; Virginia Tech Corporate Research Center with its Business and Technology Center in the New River Valley region of Virginia; and the University Research Park and its MGE Innovation Center in the Madison Metro Area of Wisconsin. These cases were selected out of a sampling frame of 15 regional cases where science parks and incubators have played significant roles in the development of their surrounding regions into viable innovation poles<sup>16</sup>. The selected sample includes diverse cases of rural/urban settings, public/private university sponsorship, technology focused/mixed use type, and with/without formal incubator facilities; and they all have a sustained operational record of more than one and a half decade. Table 1 provides a comparative overview of the benchmarking characteristics of these four US cases described below:

---

Table 1 about here

---

Situated in the New York Capital Region, Rensselaer Technology Park (RTP) is an internationally prominent science park that provides a successful model of a private university

led regional economic development. The RTP is a suburban facility established by the Rensselaer Polytechnic Institute (RPI) and is equipped with a highly successful incubator program. Besides RPI, the presence of SUNY-Albany, several technical colleges, and private R&D institutions including GE's R&D Laboratory offer a knowledge-laden environment. The area has experienced a downturn in smokestack industries during 1970s and 1980s triggering layoffs. To cope with this challenge, RPI with its visionary leadership took lead in setting up the innovation infrastructure — incubator (1980), science park (1982), and a number of interdisciplinary research centers. Several GE spin-offs by former employees along with local university alumni and students were the main sources of TBFs. Since the region possesses a broad knowledge base with strong information system and manufacturing industry, and a fairly developed seed and venture funding programs, it emphasizes diversity of technology sectors. However, software, biotech firms are dominating. This comprehensive technology development infrastructure with active private sector and supportive government policies offer a well-developed innovation milieu. A survey of RPT shows that the facility has experienced sustained growth over the more than two decades of its existence. The Park and incubator firms have experienced high survival rates with substantial innovations leveraging university technology, involvements of student interns, and alumni entrepreneurs. Both Park and its Incubator are well established award winning facilities that are considered successful science park and incubator models.

The Northwestern University/Evanston Research Park is another reputable science park situated in Evanston, a northwestern suburb of the Chicago Metropolitan Area. The park is equipped with a successful incubator. The facility is a salient example of public-private partnership where

a private research university's interest in technology commercialization prompted its leadership to team up with the host city government to offer a broader tax base with technology-oriented economy. After 15 years of sustained growth the park has recently transformed into a mixed-use business and technology park facility. The incubator portion of the park is successful in maintaining a high tenant firm survival rate, providing a sectoral focus on software, biotechnology and material sciences firms in which university has considerable strength. The facility has provided an entrepreneurial training ground for the university's students, alumni and faculty. The park is a for-profit corporation governed jointly by the university and the city of Evanston<sup>17</sup>. The incubator part is not-for-profit with strict entry and flexible exit policies that aim to support technology transfer and area's economic development through the creation and development of TBFs . With the new mixed use emphasis the park is endeavoring to maintain its technology emphasis. However, the incubator facility maintains its technology focus and is an award winning model program. As a novel experiment of university-industry-government partnership for technology development the park's Park has emphasized its role as the promoter of technology-based high value-added businesses in this economically challenged region of the industrial 'rust belt'. However, over the past several years, the park has partially been successful in attracting and retaining large R&D organizations and more recently has been relying more heavily on its incubator component in search of its coveted science park identity. The efforts are underway to transform the ambient region of the park into a fully networked modern technopole.

The Virginia Tech Corporate Research Center is a state university led science park situated in Virginia's rural New River Valley Region. Established by the Virginia Technological Institute and State University, this rapidly developing modern innovation pole offers multitude of highly

developed infrastructure located next to the University campus and offers trained manpower and university R&D results. Not only new firms based on university technology are being nurtured, but outside firms are also being solicited through generous relocation packages. The Park has experienced steady growth in physical facilities and number of tenants since inception providing technology transfer and entrepreneurial training generating substantial innovations. The park is a not-for-profit subsidiary of the Virginia Tech Foundation, which is governed by a board with broad regional representation and serves as a focal point in economic development by incubating and capturing technology-oriented firms in this rural region of the state of Virginia. Due to its technology emphasis, the entry policy is restricted toward those firms, which can benefit from regional technology resources and the exit policy is kept flexible. With its numerous value-added services the facility is making sustained efforts to tap university technology by modernizing the area's technology infrastructure through broad band connectivity and leveraging university resources. The VC and seed capital availability is limited and there are conscious efforts to improve this service by co-locating financial institutions on the park facility. The park provides a virtual incubation support to new and fledgling firms from throughout the state. A new brick and mortar technology incubator facility is being established to overcome the need for formal incubation support. New technology clusters are being developed in biotechnology and transportation and research base of the university continues to grow at about 20% per year. The CRC is becoming recognized as the center of technology development in the state and beyond.

The University Research Park in Wisconsin-Madison is a suburban park equipped with a maturing incubator facility. The focus is on university-developed technologies managed by its Wisconsin Alumni Research Foundation (WARF), specifically in the biotechnology area. The

Park is another state university led initiative that has been successful in incubating several new firms in partnership with the local private sector that is also funding the incubator operation. The facility is organized as two not-for-profit corporations, one for real estate operation and the other to run its science center. It provides shared space and office services to its client firms. Most business development services including VC and financial referrals and technology support services from university resources are available to the clients. A survey of the client firms showed that they were generally satisfied with the provision of these services<sup>18</sup>. URP is a state-of-the-art award winning park with a relatively new incubator—the Madison Electric and Gas (MGE) Innovation Center. As a unique public-private partnership for technology development, the MGE Innovation Center houses a number of new start-up firms some of which are experiencing growth and have moved to the Science Center building of the Park which provides a flexible space for expansion. The UW-Madison itself has benefited in multiple ways. Its students and faculty have enjoyed collaborations with Research Park companies through student internship programs and part-time jobs, faculty company creation and research partnerships. University's drive in technology commercialization and the promotion of its image as a partner in regional economic development has been well served.

Several lessons can be learned from these US cases:

(a) The presence of a knowledge base in the form of research universities and or major R&D institutions will serve as engine (s) of new knowledge and trained manpower. In all of the four cases the respective universities and their R&D centers played this crucial role.

(b) Successful partnerships of the university and/or R&D institution with public and private sector institutions will allow the necessary mobilization of the resources for the pursuit of entrepreneurial ventures such as access to information, shared governance, tapping university resources, availability of private venture capital. The above four cases offer salient examples of university-industry-government partnerships in most cases allowing ample sharing of resources.

(c) Presence of champions that provide the necessary motivation to initiate and impetus to persistently pursue the development of projects such as the establishments of science parks and incubators. The existence of individual and organizational champions at various levels is evidenced in all of the four cases.

(d) Once established, securing necessary funding and professional management to run these facilities that include devising entry policy to target certain technologies and allow flexible exit policy in line with the facility objectives. The provision of a comprehensive level of shared space and office services along with business and technology support are essential ingredients that add value to the tenants survival and growth needs. All four facilities have endeavored to secure necessary funding and professional management to run their facilities. Only the Virginia Tech-CRC does not have a formal incubator and lacks the shared tenet space availability, the rest of the cases provide all of the services.

(e) The performance of the science park and incubator mechanisms needs to be assessed through their program sustainability and growth, tenant firms success, overall contribution to the sponsor's mission, and the regional impacts. In all of the four cases the science parks and

incubators reported carrying out performance assessment activities through benchmarking with their peers.

### *Canadian Cases*

Four Canadian regions, Ottawa, Quebec City, Saskatoon, and Calgary Metro areas are included in the study. Each of these regions has a science park. All except Saskatoon also had one or more incubators in the 1980's or 1990's. Since 2000, additional incubators have been established in the Ottawa and Calgary regions. These regions and parks were selected from about a dozen technology intensive poles in Canada to provide examples of high-tech development in different regional environments. Lessons learned are derived from a comparison of the successful and not so successful cases.

---

Table 2 about here

---

Developed in the 1980's, the Quebec, Saskatoon and Calgary science parks had technologically-based local economic development as primary objective. No specific sectoral focus was indicated but their goal was to leverage local research activities (university, public laboratories, and local industry) and facilitate its commercialization (Table 2). The result are that parks with activities reflecting quite well with each region's research base are: optics and information technology in Quebec, agricultural biotechnology and information technology in Saskatoon,

telecommunications, wireless, geomatics and oil research in Calgary. The situation in Ottawa is different; its research park having been created in 1992 to support the development of a nascent life science sector, a new sector in an R&D intensive region active in the telecommunication, photonics and microelectronic sectors. The region has developed as a very active technology pole since the mid-1970, thanks to the presence of an industry leader (Nortel), without the help of any formal technology incubator or research park. Even if the local universities (all research-oriented) were involved in the creation of the science park and have representatives on their Board of Directors, they are only indirectly linked to park operations.

Overall, the Quebec, Saskatoon and Calgary science parks are quite successful, having been able to attract several public and private research laboratories in their early years, followed by high-tech firms, high-tech start-ups, and service organizations, to reach reasonable levels of development within a decade of their creation. The Ottawa Life Science Park, on the other hand, barely moved for ten years with a single multi-tenant building but is seeing significant development in 2003-04. The following paragraphs briefly describe each of the four science parks and their incubators:

The Innovation Place in Saskatoon has been one of the key factors in the region's success at attracting specialized federal and provincial research laboratories, quickly followed by private technology intensive firms and technology and business service firms, and helping the region become a world-class knowledge pole in agricultural-biotechnology (ag-biotech). Its success comes from the excellent collaboration between the federal and provincial governments and their decision to concentrate federal and provincial ag-biotech research activities in the park to create

a highly focused knowledge pole with the critical mass needed to become attractive to external organizations. This is an excellent example of a science park driven regional development in an isolated medium-sized community with a solid research university. With its mix of research institutes, private high-tech firms, and private technology and business service firms, the park has become a dynamic organic environment supportive of research and innovation, of public-private-university partnerships and networking, the centre of such activities in town, the place to be for science-based activities. There is no formal brick-and-mortar incubator in Saskatoon, the park itself being a solid incubation space. In 1990, Innovation Place was considered to be one of the 20 most successful University-Related Research Park in the world

One of the biggest advantages of the University of Calgary Research Park has probably been its real estate, the provision of leasable serviced land in a nice location next to the University and not too far from the center of town. As such, it has been a very useful addition to the local technology infrastructure and has contributed to the successful diversification of Calgary's economic base from its original exclusively oil-based orientation (including related research activities) into telecommunications, wireless, geomatics. The park does not have a specific sectoral focus. In addition to Discovery Place, a large multi-tenant/incubator building, it houses the research centers of several large corporations (oil and non-oil firms). Except possibly within Discovery Place, the park does not seem to have been able to develop the organic culture that facilitates and encourages informal networking between its tenant research organizations, possibly because of its urban location. In spite of its proximity to the University of Calgary, one of its founders, few university spin-offs are located in the Park. The University of Calgary Research Park is certainly a nice place to be for research-based organizations, but it is not the

only place in town for this type of activities. Starting in 1985 and during the 1990s, the Technology Enterprise Centre operated two small incubators in town, one providing support and guidance to firms renting space in Discovery Place in the park. Discovery Place is primarily an upscale multi-tenant building for technology-based firms, with common spaces, some networking activities and no exit policy. Occasional business counseling is now provided by its manager on an as-needed basis.

The Quebec Metro High-Tech Park started well, under the leadership of a university, industry, government consortium created to develop a solid high-tech base in the region.<sup>19</sup> Quebec City was (and still is) a relatively isolated medium sized government town with a good quality of life, a good research university, and a limited industrial base. The Park was supposed to be the focal point for the development of a local technology base. The Park had no official sectoral focus. It was quite successful initially, attracting early-on several public research laboratories, rapidly followed by high-tech firms, spin-offs from university and research labs, and service organizations. Those early years were facilitated by generous funding from the federal and provincial governments covering the Park's operating costs (a significant subsidy to tenants) and were made successful by solid cooperation between the various levels of government, the business community and the university. In the mid-1990, Park development stalled with the phasing-out of subsidies, reduced leadership and reduced cooperation between local stakeholders. The Park has now been privatized and its operations are financed by the sale of land to technology-based firms and research organizations. The Quebec Metro High Tech Park is still considered a prestigious address in the Quebec City region. It is however only partially developed as the availability of low cost serviced land in the area reduces its appeal. Its name

and the benefits of collocation with other technology-based organizations do not seem to be sufficient to justify the price difference. In the late 1980s, early 1990s, the Centre Régional de Développement d'Entreprises de Québec (CREDEQ) was leasing space in one of the park's buildings to incubate small technology-based firms. CREDEQ, created in 1988 by a consortium of the municipal government, the university and a job creation public organization, was financed until the late 1990s by the provincial and federal governments as well as local businesses. It was offering subsidized space and services to tech-based start-ups in the park or in its other building in town. It started well with good graduation and survival rates. It stopped leasing space in the park in the mid-1990s to save money and quickly lost its appeal for tech-based start-ups, its building in town being not close enough from the places where research and technology development were taking place.

As noted previously, the Ottawa region, a research-intensive government town, developed a solid telecommunication, photonics and software base in the 1980s and 1990s, without the use of science parks and formal incubation mechanisms, with the region acting as a "distributed incubation space". The Ottawa Life Science Technology Park was created in 1992 by the regional government and the university to be a focal point for the development of a life sciences/biotech sector close to the region's research hospitals and government laboratories. After an early change of governance<sup>20</sup> and about ten years of slow operations (with only one multi-tenant building), in 2003, the park was finally starting to develop, with the transformation of the multi-tenant building into a biotech incubator, the construction of other buildings, and the opening of another biotech incubator on land belonging to the federal experimental farm a few miles away. After a long gestation period, the life science-biotech sector in the region is starting

to grow, under the leadership of the Ottawa Life Science Council (OLSC), a public-private partnership representing local life-science interests including government research laboratories, local hospitals, the University of Ottawa and private firms. OLSC is a key driver in the development of a life-science sector in the region, and the Park, located next to the area hospitals and the University Of Ottawa Faculties of Medicine and of Health Sciences, has proved to be a focal point for the envisioned technology development.

Generalizations based on the observation of only four science parks and their incubators with different objectives located in different environments may have a low level of validity. Still, it may be useful to note that our analysis of those four Canadian cases seems to show that successful parks:

- (a) Require the solid cooperation of local and other levels of governments, local industry, and universities
- (b) Need a solid research base (research universities, public and private research laboratories) to create the critical mass needed to become attractive to other research organizations and high-tech firms and services
- (c) Benefit from the leadership of a champion, generally a local consortium of public and private organizations, firms, universities (OLSC in Ottawa, CR&DA (now CTI) in Calgary)

(d) Provide value based on the intensity of knowledge activities, networking opportunities, proximity to research laboratories or a university, availability of services, rather than monetary incentives (low rent or low fees).

### *Mexican Cases*

The Mexican regional cases included in this paper are: Queretaro-Bajío, Cuernavaca-Ensenada, Guadalajara-Monterrey, and Mexico City. Each of these four regions have technology incubators, but only two (Queretaro-Bajío, and Guadalajara) also had science parks, one of which closed in 1995. In general these incubators and science parks have encountered financial difficulties that forced a number of them to close down after some time of operation (Table 3).

---

Table 3 about here

---

In the Querétaro–Bajío region, there are two incubators: Programa Incubador de Empresas de Queretaro (PIEQ, firm incubator program of Queretaro) and Centro de Negocios e Incubacion Tecnologica (CENIT, business and technology incubation center). The PIEQ, enterprises incubator program founded in 1992 was in operation in Queretaro until 1999. CENIT, the technology incubation business center, founded in Bajío in 1996, was subsequently moved from Leon, Guanajuato to the Entrepreneurship Program in Silao, Guanajuato, which is co-sponsored by the University of Guanajuato. The San Fandila Technology Park which was developed in Queretaro went into bankruptcy by the end of 1990s.

In the mid-sized cities of Cuernavaca and Ensenada, there are also a number of technology incubation centers. The Centro de Empresas para la innovacion Tecnologica (CEMIT, technology incubator enterprises center) was established in 1991 in Guernavaca City. The Incubadora de Empresas de Innovacion Tecnologica y Admonistrativa (IETEC, incubator of management and technology innovation firms) was created in 1994, also in Cuernavaca City. The Incubadora de Empresas de Base Tecnologica (IEBT, incubator of technology based firms) in Ensenada City was also founded in 1991. These three incubators operated with some success until 1998.

In the large city of Guadalajara, the Technology Park “Los Belenes” is located at the Industrial Complex belonging to Guadalajara University. The Centro Universitario de Emprendedores Tecnologicos (CUNITEC, Entrepreneurial Center of Guadalajara University) is located inside Los Belenes Park and was established in 1992. In another large city of Monterrey, the Instituto Tecnologico de Estudios Superiores de Monterrey (ITESM, the Monterrey Higher Studies Institute) began its Entrepreneurship Program in 1985, creating a positive environment for creativity and entrepreneurial culture. By 2000s additional incubators were built such as San Pedro Garza Garcia business incubator in 2001, ITESM’s and UANL’s (Universidad Autonoma de Nuevo Leon) incubators in 2002. Other universities began entrepreneurial programs such as the UANL’s university courses which started in 1991.

In the big metropolitan area of Mexico City which includes the Federal District and 36 Mexico State’s municipalities, three innovation areas are identified. One the southern area around Universidad Autonoma de Mexico City (UNAM, National University of Mexico), the second to the north of Mexico City linking Intituto Politecnico Nacional (IPN, National Polytechnic

Institute) and, the third area, in agricultural research located in Texcoco, State of Mexico, towards the east. The fourth western area in Santa Fe is oriented toward modern corporative financial services. Two technology incubators, Sistema de Incubacion de Empresas Cientificas y Tecnologicas (SIECYT, scientific and technological firms' incubator system) established in 1991 and the Torre de Ingenieria (Engineer Tower) by the Engineering Research Institute in 1993 both at UNAM are located in the southern area. In Northern Mexico City the INCUBASK, a technology based incubator center that began its operations in 1995 at Tecamac, State of Mexico. In 2001 the Ferrerìa High Technology Park project sponsored by the Federal District Government was proposed. In East Mexico City, the Centro Empresarial Tecnológico Agropecuario Forestal (CETAF, agriculture and forestry technologies firms center) at Chapingo's University was established in 1993, but soon closed down due to management problems.

Technology incubation in Mexico has gone through several phases over the past twenty years, with periods of expansion due in part to government programs followed by periods of stagnation or of decline due to lack of continued support:

(a) The first period with high expectations took place in the early nineties. It saw the creation of CEMIT in 1990 at Cuernavaca City, of IEBT in 1991 at Ensenada, and of the SIECYT in Mexico City, the PIEQ in Queretaro and the CUNITEC in Guadalajara in 1992. After 1995 most of the incubators were shut down partly because of the lack of funds during the December 1994 national economic crisis. Only the Guadalajara incubator is still in operation. More important causes for their failure has been the lack of seed and risk capital, the rigid structures for decision making and the weak linkages with universities and research laboratories. During

this first period the Mexican Association of technological parks and incubators (AMIEPAT) was providing the orientation and promotion of technology incubators.<sup>21</sup>

(b) This period of high incubation activity was followed by a period of stagnation (1995 – 2000). This period began with the melt down of the pioneers technology incubators and ended with the creation of general purpose incubators. Even though during this period not all incubators disappeared, their number did decrease. Some isolated efforts were observed with the creation in 1995 of IPN's technology enterprises incubator centre, and in 1998 of INCUBASK incubator.

(c) After a period of stagnation, in 2001 a second period of interest in incubation started. During the second period incubators for all types of businesses in any sector including technology based firms were encouraged. **Several new** incubator projects were launched during this period in the metropolitan area of Monterrey: the San Pedro Garza García incubator (2002), the UANL incubator (2002) and the incubation system of ITESM on several of their campuses all over the country (31 incubators). The Ferreria high technology park project in Mexico City was also started at that time. A new Mexican Association of Management Incubation (AMIRE) was created in August 2003 which replaced AMIEPAT. This new association is focused on growth, creation and business consolidation to generate employment and economic development by supporting the creation, establishment and operations of high value added and technology based firms as well as commercial, industrial, services, and agribusiness firms. It also works at building knowledge-management networks, scientific and technologic parks, private capital investments firms, industrial clusters and strategic alliances. This period of renewed interest for incubation coincides with the introduction of new financing programs for small high-tech firms. Until 2003, the main source of funds for technology-based firms had been the Fondo de Inversion y

Desarrollo Tecnológico (FIDETEC, investment and development fund), a joint Consejo Nacional de Ciencia y Tecnología (CONACYT, national science and technology council) and Nacional Financiera (NAFIN, national financial institution) partnership. In 2002, the government launched the AVANCE (a high value added CONACYT) programs<sup>22</sup> for new business creation through technologic and scientific development. It includes sectoral funds, a joint creation of CONACYT's and of institutes and federal public management branch offices, to provide funds for science and technology in their sectors of competence. It also includes use of mixed funds, a partnership program started in 2001, between CONACYT and each State to provide financial backing to science and technology oriented research projects. Both programs target information technology, electronics and telecommunications, health (diagnostic systems, material equipment and drugs), land and cattle, fishing and foodstuffs, advanced materials, environment, energy, design and manufacture, dwelling and building.

(d) In 2004, the Federal Government (through the Ministry of Economics) launched a program for incubating small and medium sized firms (SMEs), with incubators associated with municipal governments, and plans to install at least one in every state. This is a joint project involving several federal authorities including Ministry of Industry and Tourism, Public Education Department, National Association of Mexican Universities and National Financial Institution (CRECE-SEP-ANUIES-NAFIN). The goal is to service 4,000 entrepreneurs during 18 months to create 2,800 SMEs.

There are several reasons for the limited success of technology incubators in Mexico, the most important of which is the shortage of funds both for incubator programs and seed and venture capital for the TBFs incubated through these programs. As mentioned earlier, rigid management

practices instead of flexible decision making processes and lack of networking are also causes for the apparent lack of performance. Though there seems to be a relationship between most local industries and the technology orientation of the incubation initiatives, yet due to the short duration of the government support for such programs did not provide enough time for incubators and parks to approach self-sustainability.

Until 2004 the regional impact of the incubation programs in Mexico has been marginal, resulting in a low visibility for such programs in general, however, incubation efforts have more visibility in regions such as Monterrey and Guadalajara where entrepreneurial culture is relatively more prevalent.

## **Synthesis and Learning**

Twelve cases from selected NAFTA regions have been presented in the previous section. Those cases illustrate the use of science parks and technology incubator as mechanisms to nurture innovative firms. The comparative analysis of these twelve cases (Tables, 1, 2, 3) shows how variable the success of science parks and of incubators is and how dependant it is on local contextual factors and on national economic and technology policies.

That variability and that dependence had been observed by Luger and Goldstein in a landmark study where they questioned the role of research/science parks as a technology innovation pole development mechanism<sup>23</sup>. They found that about a quarter of the US parks observed did achieve their goals of attracting and encouraging research and development activities and

contributing to job creation and economic growth. However, another quarter of the parks analyzed had become pure real estate ventures with little effect on local socio-economic conditions, and the rest of the parks (50 percent) failed. They argued that in many regions, science parks may not be a wise investment<sup>24</sup>. Their theory was that science parks were likely to be most successful in large metropolitan areas but that they would probably not function as growth poles there. Indeed, those areas tend to be naturally attractive to high-technology investments and to engineers and scientists because of their research intensive universities, their well developed research and development base, their business infrastructure, provided industrial development space (land, buildings) is available (thus the attraction of real estate-type business/research parks). Their assessment was that by attracting research and development activities, science parks could eventually contribute significantly to economic development in smaller metropolitan areas lacking a well-recognized university if the right investments in long-term employment were made, but that it would take more time. Their results are supported by research findings in Canada.<sup>25</sup> They are also corroborated by Donnelly<sup>26</sup> who, after observing that the most successful US research parks were associated with the nation's most research intensive universities, hypothesized that "the most privileged class of parks would appear to be those associated with large research universities located in metropolitan areas that are large enough to enjoy a critical mass of corporations, personnel, local entrepreneurs, and capital."<sup>27</sup> The success of parks associated with other types of universities would however be highly dependant on the size of their metropolitan areas, on the "energy coming from outside the institution", and on "special community assets".

In line with the lessons from these studies and given the importance of local factors on park and incubator success observed in the twelve NAFTA cases, it is appropriate to segment our analysis by type of local environment:

- Regions with well diversified economy, a broad and established industrial base and rich sources of knowledge and research activity;
- Regions with relatively diversified economy, a focused industrial base and solid research capacity;
- Isolated regions with a limited industrial base and solid research capacity
- Regions with a small research base.

*Regions with well diversified economy, a broad and established industrial base and rich sources of knowledge and research activity*

The science parks and technology incubators established in the medium to large size cities with broad and established industrial base and good research universities such as New York Capital Region (Troy), Chicago Metro Area (Evanston), Madison, Monterrey and Guadalajara, Mexico City are quite successful on the average. All the US cases have excellent parks and incubators. Guadalajara has a successful park and a good incubator, and Monterrey and Mexico City have good incubators. These parks and incubators were created to enhance a local comparative advantage (well established industrial sector or sector under transformation, field of research with solid expertise at a local university and/or research laboratory). They benefited from well

established local business cultures, local entrepreneurial spirits, infrastructures and resources (business services, financing and communications). Those science parks and incubators tended to result from solid partnerships between the local business sector, local universities and local governments. Their success is certainly due in part to good management, but also to a supportive local environment encouraging networking and cooperation for the common good. Their size (number of firms, total employment) reflects their national environment, national technology and business policies, the availability of seed and growth capital and of other business resources.

*Regions with relatively diversified economy, a focused industrial base and solid research capacity*

The science parks in Calgary, Quebec City and Ottawa, and Queretaro-Bajio were developed by local university-government-business consortia to support the economic diversification of the areas into new domains, building on local research expertise. The Calgary and Quebec parks have grown rapidly and have been great assets for the development of high-technology in their regions. They seem now to have become upscale real estate developments for technology-based firms rather than an effective incubation space facilitating networking between researchers, engineers and business persons, and promoting innovation and entrepreneurship. The Ottawa park has been slow in developing. A little over ten years after its creation, it seems that its role as focal point for a nascent health science sector has been successful and that growth is coming. The Queretaro's San Fandila Park went into bankruptcy primarily due to a lack of commitment in funding and the provision of professional management needed to acquire sustainability in due course of time. Owing to the absence of a critical mass of tangible and intangible inputs

plentifully available in the first type of regional environments (above) success in such regions require relatively more concerted efforts on the part of champion entities that may also warrant some degree of patience as was afforded in case of Ottawa but not in Queretaro.

*Isolated regions with a limited industrial base and solid research capacity*

The science parks in Saskatoon and Virginia's New River Valley (Blacksburg) have been very successful at growing a quality innovation pole around a solid research base of a major university in their isolated smaller communities. Their success comes from a close cooperation of stakeholders (university, business, and governments) and on site availability of all the business resources and services needed by TBFs. Both parks behaved as solid incubation spaces and did not see the need for formal incubators until recently. Their challenge is now to attract venture capital to continue to grow their high-tech firms.

*Regions with a small research base*

Technology incubators in Cuernavaca and Ensenada have been unsuccessful, even if those regions have reasonable research bases and good universities. Those incubators facilities were mostly government supported research center or university driven in regions that seem to lack the culture of networking and entrepreneurship found in more successful places. Lack of government support for research, for high-tech start-ups and for the incubation program

compounded the negative impact of the absence of linkages between researchers and the business sector.

*The lessons from those case studies show clearly that:*

- The regional environment and local business culture are major determinants of the success of incubation mechanisms. Science parks and incubators can contribute very significantly to the transformation and growth of a region into a successful knowledge pole, but they are not sufficient to bring change. The parks provide an enabling milieu by leveraging regional resources to successfully nurture TBF's. They contribute to the critical mass of services and other support mechanisms offered in the region, facilitate networking and exchanges between the local research university, researchers and engineers, and entrepreneurs, and are therefore an important asset in local development.
- The full cooperation and active support of the local research university, local and other levels of government is needed for science parks and incubators to be successful. In terms of governance, most of the U.S. parks have boards with representations from the key stakeholders, which provide policy guidance. Typically, a director heads the park management team and the incubator manager generally reports to the park director as is the case of the four parks studied. However, in a number of other U.S. facilities incubators operate independently of the parks. In Canada, universities, federal, provincial and local levels of government, and the private sector are represented on the boards of all

science parks, but the parks are generally managed by independent non-profit organizations. In Mexico a typical incubator management board is based on partnership of government, university (or a research center), and some private institutes, which help them to be classified according to the lead agent. Government incubator leadership may be federal, state or municipal. There also may be a mix, such as PIEQ's management board, as CONACYT (federal government) is participating with the Queretaro's State government. But, in general the universities have been the dominant institution in half of the incubators

- Key to park success is the provision of a non-monetary value proposition related to R&D (geographic and sectoral concentration of R&D activities, proximity to a university or a large research laboratories, presence of large anchor organizations) and to the availability of business services (often through independent private firms located in the park or in the incubator). Below market prices or other monetary incentives are better avoided as they attract organizations that may not be as solid as needed to ensure fit necessary for providing survival and growth environment.
- Most technology incubators in this study tend to operate independently from the parks and from the universities, although this is not the case for all technology incubators especially in Canada.<sup>28</sup>

In summary, the successful development of an innovation pole depends on a number of players (university, business, government), and on local entrepreneurial and innovative culture. Science

parks and incubators can contribute significantly to stimulate the development of innovative SMEs in their regions. Their success for the creation and growth of SMEs as enabling incubation spaces depends on local culture and on the level of cooperation between the key players

Table 1: Comparative Overview of the US Cases

| Surrounding Region                                 | Medium Size City Urban Area (Troy, NY)  | Large City Region Suburban Area (Evanston, IL)  | Small Size City Rural Area (Blacksburg, VA)   | Medium Size City Semi-Urban Area (Madison, WI)  |
|--|---|---|---|---|
| <i>Science Park/ Incubator</i>                     | <i>RPI Technology Park</i>  | <i>Northwestern University/ Evanston Research Park</i>  | <i>Virginia Tech Corporate Research Center</i>  | <i>University Research Park, Wisconsin</i>  |
| <i>Facility Background</i>                         | A suburban park with a solid incubator facility, established in 1982 by RPI. About 80 firms and 2000 employees. Broad range of university and area technology focus.  | A suburban mixed-use facility with incubator, established in 1985 by NU with city's participation. About 62 firms, 1000 employees. Software, biotech, materials focus   | A rural park with a virtual but developing incubator facility. Established in 1985 by VT. About 104 firms and 1800 employees. Broad range of university technology  | A suburban park with maturing incubator. Established in 1984 by UW. About 110 firms and 2300 employees. Focus on biotech and other areas of university technology   |
| <i>Performance Outcome</i>                         | Sustained growth over the past 2+ decades. High firm survival rate with substantial innovations and involvement of university technology, entrepreneurs and alumni.   | After 15 yrs of sustained growth, park transformed into mixed use. High firm survival rate at incubator with successful firms. Entrepreneurship training for students/faculty   | Experienced fast growth in facilities and tenants since inception. Salient efforts in university tech tr. and enterer. training. Steady tenants generating substantial innovations                                  | Sustained growth in park over the past 2 decades. Significant efforts in university tech. tr. though WARF. Created successful firms and partnered with private sector to help incubate new firms                                  |
| <i>Management Policies and Their Effectiveness</i> | Governed by RPI board of trustees. Funded by RPI, state funds. Strict entry and flexible exit criteria. University training & tech trans., regional. economic development objectives achieved.                | Park is for profit corp. governed jointly by university and city, though recently the city has pulled out. Incubator not-for profit with strict entry and flexible exit criteria. Tech trans, training, area econ. development objects achieved | Park is not-for-profit subs. of VT foundation. Governed by board with regional reps. Strict entry and flexible exit criteria. Serves as a focal point in econ. dev. of the region                                   | Park is organized as 2 not-for-profit corps. under university trustees. Strict entry and flexible exit criteria. Serves as a focal point in mobilizing university developed technology for regional development                   |
| <i>Services and their Value Added</i>              | All shared services. Business and technology development services, seed cap and VC access, info databases, tech tran., access to university resources. Tenant satisfied with support & avail of RPI resources | Most shared services, bus and tech dev services, easy seed cap and VC access, info databases, tech tran., access to university resources. Tenant generally satisfied with support & avail of NU resources                                       | Limited shared park services, including and tech dev services, efforts to provide seed cap and VC access, info databases, tech tran., access to university resources. Formal incubator facility is being developed. | Increasingly developed park and incubator shared services, bus and tech dev services, easy seed cap and VC access, info databases, tech tran., access to university resources. Tenant satisfied with support & avail of resources |
| <i>Overall Assessment:</i>                         | Award winning successful facility serving as a model. Continued efforts to involve stakeholders, and attract talent & technology.   | The facility has an award winning successful incubator. With the mixed use approach for the park, efforts are underway to maintain university tech trans. focus.  | A modern and growing park facility with virtual incubation component. Sustained efforts to capitalize on university tech and developing area innovation infrastructure.   | A state of the art park with a private sector supported incubation operation. Developing a model tech entrepreneurship infrastructure based on university's R&D strengths.  |

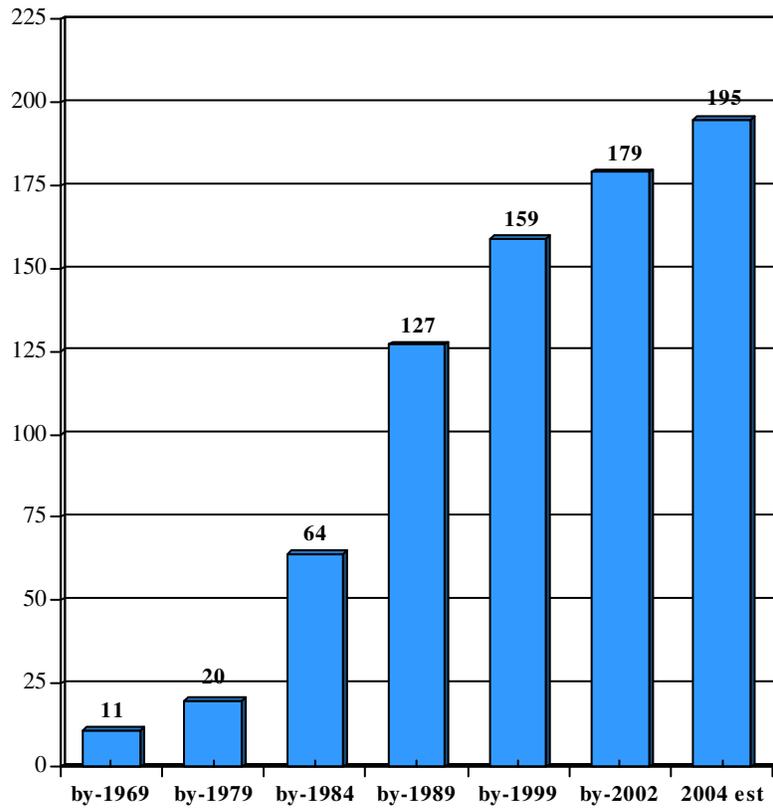

Table 2: Comparative Overview of Canadian Cases

| Surrounding Region                                 | Medium Size City Urban Area   | Medium Size City Urban Area   | Small Size City Rural Area   | Medium Size City Urban Area   |
|--|---|---|--|---|
| <i>Science Park/ Incubator</i>                     | <i>Ottawa Life Science Technology Park</i>  | <i>Quebec Metro High-Tech Park</i>  | <i>Innovation Place</i>  | <i>University of Calgary Research Park</i>  |
| <i>Facility Background</i>                         | Urban park created in 1992. A biotech incubator built 2002; until then mostly multi-tenant building (8 tenants, 40 employees in 2001. Strictly focused on health sciences and biotech.  | Suburban park created in 1983 for regional econ. diversification by local, provincial, fed govts. CREDEQ incubator until the late 1980's. Research on IT, telecom, opto-electronics, new materials, nordicity, forestry. In 2001, 100 orgs (14 buildings), 2500 employees.                      | Urban park created by Province and Univ of Saskatchewan in 1977 on university land. No formal incubator. Main focus on Ag-biotech, but also IT, electronics and related support services. Around 115 organizations, 2200 persons in 23 buildings   | Urban park created in 1983 by city, Chamber of Commerce and university on government land. Technology incubator in multi-tenant building in Park (now named Alastair Ross Tech Centre). No sectoral orientation; mainly IT, telecom, software. Over 3000 persons in 7 buildings.  |
| <i>Performance Outcomes</i>                        | After ten years of slow development, the biotech/health sector in Ottawa seems to be picking-up steam; two biotech incubators have been built in 2002. The Park seems to finally start growing. Was probably one of the catalysts for the growing biotech cluster in Ottawa | Successful at first with govt. Funding. Difficult times in mid-late 1990's with phasing-out of government support. Privatized, not-for-profit, to continue to develop/sell land for high-tech activities. Contributed to the dev. of Quebec's small high-tech base                              | Very successful, due to Province's full commitment and management team's clear focus and commitment First 5 tenants were provincial organizations. Considered one the 20 best "University-Related Parks" in the world in 1990. Key factor in the development of the region as a world class ag-biotech centre. | Excellent location for R&D activities, with an up-scale multi-tenant building. Multi-tenant building worked well as incubation space; rest of park mostly high-tech real estate. Has definitely contributed to the high-tech development of the region by providing well located quality space for R&D activities.                |
| <i>Management Policies and their Effectiveness</i> | City, local universities, provincial government, federal government, and local industry on governing board. Managed by OLSC, not-for-profit consortium dedicated to development of health science in region. Funded by Ottawa city, industry, other levels of government.   | Large 26 person board of directors with university, business, government. Was offering subsidized business services and networking opportunities until government funding stopped. Now mainly private non-profit high-tech real estate service.   | Nine members board, 3 from the University, others named by Innovation Place, subject to University approval. Managed by provincially-funded public entity. More university involvement expected as provinces reduces its involvement/funding. (2003-04)  | Twenty six persons board with representation from the Univ. of Calgary, Alberta Research Council, Govt. of Alberta, and private industry. Managed by non-profit entity. CTI financed about 50% by local, provincial, federal governments, 40% own revenues from services.   |
| <i>Services and their Value Added</i>              | Usual services offered in a multi-tenant building, including reception and conference space. Networking opportunities, workshops. Prime urban location for health research activities, next to hospitals and medical school; focal point for nascent health science cluster | Business services to SMEs provided by park administration: technology assessment, business planning, export promotion, marketing, etc.; networking activities and workshops, seminars. High concentration of research; regional pole in optics; excellent location; offers prestigious address. | Most business services offered by to park tenants, business, accounting, legal, IP issues, networking activities, workshops, seminars; access to fully equipped laboratories, etc. High concentration of research; availability of all business services; a very good address; high-tech nucleus of region     | Some business services available in Discovery Place (now Alastair Ross Tech Centre), large multi-tenant and incubation building in Park. Access to University facilities. High concentration of research, in domains representative of local high-tech-base; closeness to university, good support services, a very good address. |
| <i>Overall Assessment</i>                          | First 10 years very slow; with the opening of the Ottawa Biotech Incubation Centre (OBIC) in 2002, the park seems to finally start growing; it has been the catalyst for the growing biotech cluster in Ottawa.   | Started well with govt. funding; went through difficult time in mid-late 1990's with the phasing-out of public funding; has been a focal point for local high-tech businesses; now in danger of losing its science orientation and becoming only a nice industrial real-estate park.            | Overall, highly successful, current challenge is to attract venture capital to sustain the growth of its small firms; may suffer from current questioning on genetically modified plants.  | Quite successful as an up-scale high-tech real-estate development, with well located land for R&D activities; has definitely contributed to the high-tech development of the region; unclear if it has contributed to the creation of many high-tech spin-offs (except at Discovery Place)  |

**Table 3: Comparative Overview of Mexican Cases**

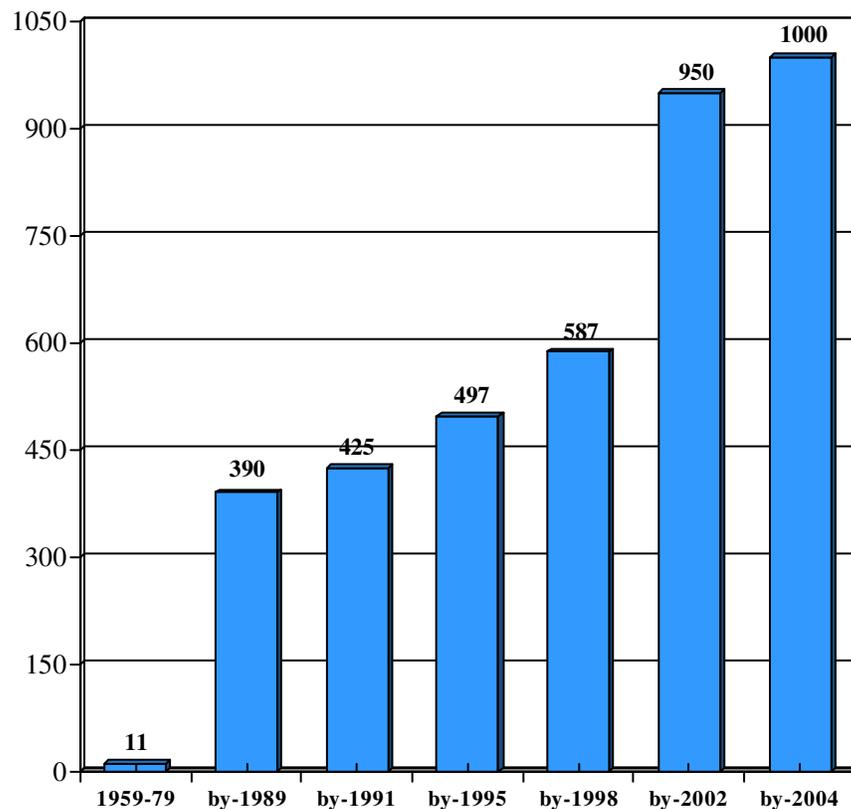

| Surrounding Region                                 | Small Size Cities  |   | Medium Size Cities  |  | Large Cities   |   | Mexico City  |
|--|--|---|---|--|--|---|--|
|  | Queretaro - Bajio  |   | Cuernavaca  | Ensenada   | Guadalajara  | Monterrey   |  |
| <i>Science Park/ Incubator</i>                     | <i>PIEQ/San Fandila</i>  | <i>CENIT</i>  | <i>CEMIT, IETEC</i>   | <i>IEBT</i>  | <i>CUNITEC/Tech Park Belenes.</i>  | <i>ITESM Incubator program</i>  | <i>Siicyt-UNAM, "Torre de Ingeniería"-UNAM, CETAF-UACH, CIEBT-IPN e INCUBASK- UAEM.</i>  |
| <i>Facility Background</i>                         | Operated during 1992-1999. It had 3 graduated firms out of 25 tenants. PIEQ is located in the San Fandila Park which did not take off.   | Established in 1994 at Delta Industrial Park (Leon, Gto). In 1996 changed to an Ind-Univ Collaboration Program (VEN, Silao, Gto).   | CEMIT founded in 1991. IETEC was established by ITESM in 1994. Both were in operation until 1998 after which they were closed down.   | Started operations in 1991 and closed down in 1998 after seven years of operation.   | Created in 1992 at "Los Belenes" Tech Park. There are 23 tenants, out of which 8 graduated. The Park, has 13 firms.  | ITESM incubator program started in 1985. There are 3 incubators operating: San Pedro Garza García (2001), ITESM incubator (2001), and UANL incubator (2002).                              | There are 5 Incubators. The first 3 which are pioneers went into bankruptcy. IPN's and INCUBASK are operating. INCBASK has 10 tenants and one grad. Second generation incubators have diverse all types of firms |
| <i>Performance Outcomes</i>                        | Poor performance and failure primarily due to lack of financial resources to operate the facility and support TBFs activities. Replaced by a Research Center   | Now the incubation of tech firms is only one of its multi entrepreneur functions at VEN. The firms' creation has lower priority. Hence no significant regional impacts                | No funding was available for continued operation. The Cuernavaca area has developed a strong R&D infrastructure and benefits from its location close to Mexico City.                                    | Causes of closing are due to lack of risk capital. Incubator is more a result of technology push than a pull of the local demand, which is limited for this type of project. | There is no seed and risk capital available. The regional impact is low. But due to the sustainability of both incubator and tech park the symbolic impact is there. | There are no funds for risk and/or seed capital. Teaching entrepreneurship is an important activity of ITESM. The second generation mixed use incubators are the outcome of this program. | Lack of seed and capital risk are the main causes of first generation incubators closing. The impact of incubators is marginal. It is more a push idea to reality.   |
| <i>Management Policies and their Effectiveness</i> | Queretaro State Govt leads PIEQ's activities, jointly with CONACYT. CONACYT and NAFIN provided financial backing for 3 years.  | CENIT had a Leon City hall and a research Center governance. But now VEN is under Guanajuato University. The main funding was provided by CONACYT, NAFIN and State government of Gto. | CEMIT has a large cumbersome board of governance with a research center (IIE) in the leadership position. NAFIN, backs its activities. IETEC has been an ITESM local campus incubator.                  | A large board led by a Research Center (CISECE). Incubator set up was made possible by Cicese financial support. Additional risk capital came from Conacyt-Nafinsa fund.     | There is a large board and Guadalajara university is the lead institution. However management decision making need to be more flexible and efficient.                | Universities are the main agents to settle incubation spaces (ITESM and UANL). It is a case of local municipal government led incubator as the San Pedro Garza Garcia.                    | Universities (UNAM, IPN) are the main leaders in Mexico City incubators. But university culture does not generally match with the firms needed business environment.   |
| <i>Services and their Value Added</i>              | Incubators help in sharing information, to create a positive tenants association to attend outside demands. Due to cash shortages often have problem to cover incubator rent and common services.    |   | Cuernavaca has a better R&D knowledge infrastructure and keeps a good knowledge networking.   | Incubator has a good support from Cicese in knowledge networking.  | An anchor machine tool firm helps the incubation of other firms. There is strong networking support.   | The second generation incubators have less risk tenants as most of them are not TBF. So the incubators services are mainly sharing common costs by tenants.                               |  |
| <i>Overall Assessment</i>                          | The lack of funds and risk capital has a general effect on tenant's success. Potential tenant firms networking with the large research infrastructure is not fully used for technological innovation |   | Incubator bankruptcy due to: 1) lack of seed and risk capital; 2) rigid and slow decision making due to overloaded institutional governance 3) too strict breakeven for money self sufficiency (IETEC). |  | Sustainability of the incubator and Park is due to flexible decision making and networking support   | Better chances of success due to a tenants mix of TBF with traditional firms. Availability of public funds for spin offs (AVANCE), as well as State Gov support.                          |  |

## **GENDER DIFFERENCES OF SMALL COMMUNITY BUSINESS OWNERS IN NETWORK MEMBERSHIP PERCEPTIONS**

Nancy J. Miller, 203 HE Building, University of Nebraska- Lincoln, Lincoln, NE 68583

Terry L. Besser, Iowa State University

Jennifer V. Price, University of Nebraska-Lincoln

### **ABSTRACT**

This research examined concepts inherent in social capital and strategic network theory. Data was collected from 277 men and 100 women, who in addition to operating a small business in a small community, were members of one of twenty-nine business networks. The variables of shared vision, resource sharing, business activities, and advantages to networking, were regressed on owners' desire to continue network membership. Gender differences in owners' personal and business characteristics in relation to continued network membership were also explored and found significant, thus requiring the use of control variables in the subsequent analysis. In a hierarchical order of entry, gender, years of ownership, gross sales, and numbers of employees were first entered for statistical control. Results of hierarchical multiple regression suggested that advantages from networking and a shared vision significantly explained owners' desire to continue their network membership, with control and network variables also included in the equation. Examination of the interaction effects of gender on each of the four network-based variables suggested that gender with resource sharing also significantly explained the owners' desire to continue network membership. The total  $R^2$  for the seven steps in variable entry equaled .505. On the basis of these findings, we suggest there are descriptive differences among male and female small business owners, such as in business size and age, that should be further explored. Variables central to social capital and strategic network theory held a positive effect on members' future network membership plans thus furthering the likelihood of the networks' future existence.

## **ABSTRACT**

This empirical study aims to understand how entrepreneurs mobilise social capital. A survey of 325 entrepreneurs from the KwaZulu-Natal province of South Africa was conducted. Analysis of variance, factor analysis and discriminant analysis was performed on a 20-item scale on social capital variables. Results indicate that among the three ethnic groups of entrepreneurs studied, Europeans mobilised social capital better than their Indian and African counterparts. Europeans tend to favour more formal avenues of accessing social capital while Indian respondents tend to prefer informal means. The discriminant analysis findings show that the social capital scale can accurately distinguish between the three ethnic groups.

## **INTRODUCTION**

The concept of social capital has been recognised by sociologists and economists as an alternative to traditional forms of capital, such as financial, physical, and human (Marger, 2001). Social capital may be defined as those resources inherent in social relations that facilitate collective action. The critical issue is that norms of trust, obligation and reciprocity are established through membership in these social networks (Coleman, 1988; Putnam, 1993; Light and Gold, 2000, Portes and Sensenbrenner, 1993; Onyx and Bullen, 2000; Fukuyama, 1995). In addition, social capital is an entity, consisting of all expected future benefits derived not from one's own labour, but from linking with other persons. It is from this membership of a network that individuals are able to obtain scarce resources. Social capital does not constitute the resources themselves, but rather the individuals' ability to mobilise these resources on demand (Portes, 1995).

## **KEY LITERATURE**

### **Social capital**

Portes (1998) argues that the concept refers to dense interlocking networks of relationships between individuals and groups. People engage with others through a variety of lateral

associations, which must be both voluntary and equal (Onyx and Bullen, 2000). Social capital cannot be generated by individuals acting on their own in isolation. It depends on a proclivity for sociability, but a spontaneous sociability, a capacity to form new associations and to co-operate within the terms of reference they establish (Fukuyama, 1995).

Nahapiet and Ghoshal (1998) state that the crucial issue of social capital theory is that networks of relationships constitute a valuable resource for the conduct of social affairs, providing their members with “the collectivity-owned capital, a ‘credential’ which entitles them to credit, in the various senses of the word” (Bourdieu, 1986: 249). Much of this capital is embedded within networks of mutual acquaintance and recognition. Bourdieu (1986), for example, identifies the durable obligations arising from feelings of gratitude, respect, and friendship or from the institutionally guaranteed rights derived from membership in a family, a class, or a school. Other resources are available through the contacts or connections networks bring. For example, through “weak ties” (Granovetter, 1973) and “friends of friends” (Boissevain, 1974), network members can gain privileged access to information and to opportunities. Finally, significant social capital in the form of social status or reputation can be derived from membership in specific networks, particularly those in which such membership is relatively restricted (Bourdieu, 1986; Burt, 1992; Nahapiet & Ghoshal, 1998).

### **Ethnicity and social capital**

Ethnic groups are capable of providing members with social capital. Denoting the web of connections, loyalties, and mutual obligations (shared fate, solidarity, and communal membership) that develop among people as part of their regular interaction, social capital refers to the sense of commitment that induces people to extend favours, expect preferential treatment, and look out for one another’s interests (Light and Gold, 2000). The ethnic base of social capital becomes apparent when co-operation and mutual aid develop among group members of disparate class origins, who would often provide co-ethnics with higher wages and better benefits than out-group consideration and respect. Ethnic resources may yield benefits to an entire group. However, financial, human, cultural, and social capital are often more extensively amassed and shared among subcollectivities wherein control is greater and malfeasance less likely. Granovetter (1985) demonstrates that the value of social capital is often enhanced when it is confined within specific boundaries or, in other words, constrained by both “coupling and decoupling”. In order to optimise their economic position, group members benefit not only by co-operating among themselves, but also by minimising obligations to others, such that gainful action will be unfettered (Light and Gold, 2000: 112).

Portes and Sensenbrenner (1993) redefine social capital as “those expectations for action within a collectivity that affect the economic goals and goal – seeking behaviour of its members, even if these expectations are not oriented towards the economic sphere (Portes and Sensenbrenner, 1993: 1323). Relating to immigrants and their adaptation to the host society, social capital essentially refers to participation within social networks of kin and especially co-ethnics. Such networks may influence immigration decisions, settlement pattern, and social incorporation (Marger, 2001; Massey et al, 1993). In brief, ethnic networks provide immigrants with a support system that assists in the securing of housing and other initial settlement issues, yields crucial information regarding job opportunities, and boosts psychological security in a shortage in a strange environment. These networks can take the form of ethnic voluntary associations, community ties to the origin society, and local ethnic communities and neighbourhoods that emerge in the host society (Marger, 2001).

### **The African Context**

Kinunda-Rutashobya (1999: 24) calls for more empirical work especially in the African context and contends that reasons for success of one ethnic group over another can be further understood by network theory. This perspective is supported by the research of Godsell (1991), in her study of four ethnic groups in South Africa. She found that although both Indian and African entrepreneurs were victims of discriminatory legislation, the Indian entrepreneurs were able to use resources provided by family and the community, which included the local, national and international community. Among the African entrepreneurs, very few networks were found, which was attributed to the low status of small business in the African community. A further explanation for this lack of networks was the perception that traditionally African entrepreneurs have had very few entrepreneurial role models. In trying to explain the lack of entrepreneurship among African entrepreneurs in the UK (Basu & Goswami, 1999; Ram, 1994, 1997), and in the US, (Light & Gold, 2000; Yoo, 2000), it is argued that one feasible explanation was that there was a shortage of entrepreneurial role models in their community.

Ram (1997: 149) and Basu and Goswami (1999: 251) argue that ethnic minority businesses often arise out of a context of disadvantage, and that the adverse “opportunity structure” carries greater explanatory power than speculations on “culture” and so-called “ethnic” resources. Sanders and Nee (1996: 233) accept the importance of social capital in explaining interethnic variations in self-employment, but locate the relevant social unit as the immediate family rather than the immigrant community. As a social organization of production, the family’s chief advantages are not simply tangible products, such as unpaid labor, but also involve the mutual obligation and trust characteristic of solidaristic small groups.

In a study in Africa, Brown and Butler (1993) claimed that strong ethnic and cultural ties can act as barriers to those entrepreneurs who are not members of the ethnic group. For example, in Zambia, a large proportion of the business sector is run by Asian immigrants, who are not bound by the cultural factors in the country, and the production and trade of indigenous goods, as well as trade in imported goods were discouraged among “natives” by colonial economic policies (Kobonyo, 1999). Based on research in Kenya, Africans found it very difficult to penetrate business sectors dominated by Asians. This is largely due to social networks among the Asian business operations, which excludes non-Asians.

## **RESEARCH METHODOLOGY**

Data for the analysis was collected from 325 entrepreneurs in Durban, the largest city in the province of KwaZulu-Natal, South Africa. Entrepreneurs were requested to fill in a structured survey instrument to ensure reliability and validity in responses obtained. The sample was selected from entrepreneurs from the three dominant ethnic groups in the region: African, Indian and European. The three ethnic groups chosen for this study will contribute more to our understanding of how social capital is mobilised by entrepreneurs within a developing country. The African entrepreneur group is an example of a marginalised group, but in South Africa, they are a majority, and not a minority group. Therefore by studying this group will add to our understanding of entrepreneurship in this context. Also this group is not an immigrant group, but an indigenous group, and it is important when comparing ethnic groups to have a “native” group. The Indian ethnic group is an example of a group filling the “middleman minority” group. However, in South Africa, they were also marginalised by institutional factors, and will therefore make for an fascinating study. The European ethnic

group also have a long history in South Africa, but their position in South Africa has always been one of privilege, and was originally one of being the colonial power. However, with change, firstly with the Afrikaner-led government and then the Black-led government in 1994, their position has changed dramatically.

The sample was selected largely by personal contacts and referrals and introductions by those interviewed. Given that a large amount of ethnic businesses are still operated in areas dominated by specific ethnic groups, research assistants from the same ethnic group as the respondents' were used. This methodology was utilised by Ram (1994) and Basu and Goswami (1999) in studies conducted in England, and Light and Bonacich (1988) in studies in the US, whereby having interviewers with the same ethnic background led to more access and acceptance by the entrepreneurs. The data analyses consisted of an ANOVA to determine whether there were any significant differences between the mean scores of the three ethnic entrepreneur groups in the social capital variables. Furthermore, a factor analysis was performed to determine the underlying social capital factors. In addition, the scale was subjected to discriminant analysis to ascertain whether the scale could significantly distinguish between the three ethnic groups.

## RESULTS AND DISCUSSION

This section presents a profile of some of the characteristics of the entrepreneur in addition to the results of the analysis of variance, factor analysis and discriminant analysis on the social capital variables.

To determine whether there were significant differences in the various social capital variables among the three ethnic groups, an analysis of variance (ANOVA) was performed. The results are shown in table 1. Of the 20 items included in the questionnaire, at  $p \leq .001$ , 12 were found to be statistically significant when ethnic groups was used as a differentiating factor. The results of table 1 indicate that African respondents have two of the highest means and nine of the lowest means in the 12 significant items. They scored the highest in joining a local community action to deal with an emergency and thinking that multiculturalism makes life better. They scored the lowest in feeling valued by society, satisfaction with the meaning of one's life, believing that by helping others one helps oneself, attending a local community event, feeling that the local community is like home, going outside the community to visit family, running into friends and acquaintances when shopping, knowing where to find information to make a life decision, and feeling free to speak out when one disagrees with everyone else.

-----  
Table 1 Here  
-----

As for the Indian respondents, the results indicate that they scored the highest in five items and lowest in three items. They scored the highest in the following items: feeling valued by society, satisfaction with the meaning of one's life, attending a local community event, going outside the community to visit one's family, and running into friends and acquaintances when shopping. They scored the lowest on being in a management or organising committee for any local group or organisation, joining local community action to deal with an emergency, and thinking that multiculturalism makes life better.

The results of the European entrepreneurs indicate that they scored highest in five items and none lowest. The five highest scoring items were – believing that helping others helps oneself, feeling that the local community is like home, knowing where to find information, being in a management or organising committee for a local group or organisation, and feeling free to speak out when one disagrees with everyone else.

A factor analysis was also performed on the social capital questions. Findings from the factor analysis illustrated in table 2 show the emergence of a six-factor solution that accounts for 63.078 percent of the variance.

-----  
Table 2 Here  
-----

**Factor 1: Participation in community activities**

This factor had six item loadings and included the following items: joining local community action to deal with emergency, participating in community project, being in a management/organizing committee of local group, helping organize new service in the area, being an active member of local organization or club, and helping out a local group as a volunteer. This factor deals with the entrepreneurs' level of participation in community activities. The component loadings ranged from 0.488 to 0.756.

**Factor 2: Proximity of network members**

This factor had four item loadings ranging from 0.484 to 0.715, and included items such as: attending local community events, running into friends and acquaintances when shopping, going outside the community to visit family, and feeling that the local community is like home. This factor related to the proximity of entrepreneurs' network members.

**Factor 3: Perceptions of contribution to society**

This factor had three item loadings ranging from 0.544 to 0.825 and included the following items: feeling valued by society, feeling satisfaction with what life meant, and believing that helping others helps yourself. This factor deals with the entrepreneurs' perceptions on his/her contribution to society.

**Factor 4: Attitude towards multiculturalism**

This factor had two item loadings ranging from 0.862 and 0.864 and included items such as enjoying living with people of different lifestyles, and thinking that multiculturalism makes life better.

**Factor 5: Perceptions of safety and trust**

This factor had three item loadings and included items such as: feeling safe walking down one's street after dark, having a reputation of one's area being a safe place, and agreeing that most people can be trusted. This factor deals with the respondents' perceptions of how safe one's area is as well as how trustworthy people generally are. The component loadings range from 0.542 to 0.783.

**Factor 6: Access to and freedom to provide information**

This factor had two item loadings ranging from 0.525 and 0.766, and included the following

items: knowing where to find information when making life decision, and feeling free to speak out when one disagree with everyone else.

The initial-components factor analysis method was used to determine the number of possible factors present. From the eigenvalues greater than one (refer to table 3), it was decided to have six factors because the eigenvalues of the seventh factor onwards was less than one. In order to determine a finer selection of factors, an orthogonal varimax rotation was completed. The factor loadings for each of the six factors are greater than 0,35. All the eigenvalues for the respective factors are greater than 1,0 which fulfills the Kaiser criterion.

-----  
Table 3 Here  
-----

The six factors and their relative contribution to variance are presented in table 3. It can be seen that all the six factors have an eigenvalue of above 1, ranging from 1.008 to 4.100. Factor 1, participation in community activities, contributes a variance of 20.499 percent, followed by factor 2, proximity of network members, which contributes 14.654 percent. Perceptions of contribution to society, factor 3, contributes 9.678 percent of the variance, while factor 4, attitude towards multiculturalism, explains 7.182 percent of the variance. Factor 5, perceptions of safety and trust, contributes 6.025 percent in explaining the variance while factor 6, access to and freedom to provide information contribute 5.040 percent. The total cumulative variance explained by the six factors is 63.078 percent.

The data collected were also subjected to item analysis. The Cronbach's alpha coefficient ( $\alpha$ ) was calculated to determine the internal consistency of the items on the scale. The alpha value for the entire social capital scale was found to be 0.7757, which indicated that the internal consistency was quite high. Cronbach's alpha coefficient for each factor of the scale were as follows: factor 1 = 0.7746; factor 2 = 0.6823; factor 3 = 0.7255; factor 4 = 0.7975; factor 5 = 0.5226; and factor 6 = 0.5035.

Discriminant analysis was also performed on the data to determine whether the social capital scale can accurately classify the respondents according to their ethnic groupings. The results of this analysis is presented in table 4.

-----  
Table 4 Here  
-----

The results indicate that using the social capital scale, the overall classification accuracy (hit ratio) is 63.04 percent. Of the 111 African entrepreneurs, 65 were correctly classified, accounting for 58.56 percent. Among the 121 Indian respondents, 84 were correctly classified, corresponding to 69.42 percent. As for the Europeans, of the 90 respondents, 54 were correctly classified, equivalent to 60 percent.

A measure of classification accuracy is the maximum chance criterion which is simply the hit ratio obtained if we assign all the observations to the group with the highest probability of occurrence. In the computation, this results to 37.58 percent. Compare this figure to the overall percentage correctly classified. Based on the maximum chance criterion therefore, the

model is very good. Another measure of classification accuracy is the proportional chance criterion which is calculated by squaring the proportions of each group, with the calculated value of 34.16 percent which is lower than the overall percentage correctly calculated as well as the individual group's percentage correctly classified. Hence, based on the proportional chance criterion, the model is very good.

## CONCLUSION

As the literature indicates (Portes, 1995) social capital refers to the individual's ability to mobilise resources. For entrepreneurs to be successful they need to be able to obtain scarce resources through various sources. It is important for them to establish relationships with others in order to access these resources. The findings indicate that among the respondents from the three ethnic groups, the Africans scored the lowest and the Europeans scored the highest in the social capital variables. This shows that the African entrepreneurs do not mobilise social capital as well as their Indian and European counterparts. These results support Godsell (1991)'s findings that Indian entrepreneurs access social capital better than Africans.

The way social capital is accessed also differs according to the respondent's ethnic grouping. European entrepreneurs tend to access social capital in more formal avenues such as participation in management or organising committees for local groups. Indians tend to rely on more informal means of gathering social capital such as through family, friends and acquaintances. It is quite interesting to note that for the African respondents, they scored the highest in the item related to joining a local community action to deal with an emergency. This could indicate that Africans only mobilise social capital when there is no choice and do not make a conscious effort to cultivate and maintain relationships that would help in this aspect.

To conclude, this paper has attempted to add to our understanding of ethnic entrepreneurs in South Africa. It is widely accepted that entrepreneurship is a social activity, embedded in a social context. Therefore, in line with the mixed embeddedness perspective, there is a need to examine the influence of the wider socio-economic and politico-institutional environments on entrepreneurship.

**Table 1: Mean Scores from Questions on Social Capital**

| <b>Question</b>  | <b>African</b> | <b>Indian</b> | <b>European</b> | <b>F-value</b> |
|--|----------------|---------------|-----------------|----------------|
| Do you feel valued by society?   | 2.66           | 3.56          | 3.11            | 14.934*        |
| If you were to die tomorrow, would you be satisfied with what your life has meant?                 | 2.38           | 3.49          | 3.04            | 19.846*        |
| Do you believe that by helping others you help yourself?   | 3.02           | 3.60          | 3.80            | 14.383*        |
| Do you help put a local group as a volunteer?  | 2.32           | 2.60          | 2.35            | 1.138          |
| Do you feel safe walking down your street after dark?  | 2.07           | 1.78          | 1.56            | 4.555          |
| Do you agree that most people can be trusted?  | 2.15           | 1.77          | 2.07            | 3.505          |
| Does your area have a reputation for being a safe place?   | 2.31           | 1.95          | 2.44            | 5.198          |
| Have you attended a local community event in the past 6 months (e.g. church fete, school concert)? | 2.31           | 3.45          | 2.98            | 18.719*        |
| Are you an active member of a local organization or club (e.g. craft, sport, social club)?         | 2.21           | 1.88          | 2.32            | 3.460          |
| Does your local community feel like home?  | 2.40           | 2.73          | 3.27            | 9.625*         |
| Do you go outside your community to visit your family?   | 2.53           | 3.79          | 3.69            | 48.957*        |
| When you go shopping in your local area are you likely to run into friends and acquaintances?      | 2.62           | 3.78          | 3.69            | 44.883*        |
| If you need information to make a life decision, do you know where to find that information?       | 2.67           | 3.29          | 3.62            | 17.188*        |
| Are you on a management committee or organizing committee for any local group or organization?     | 2.10           | 1.57          | 2.22            | 6.905*         |
| In the past 3 years, have you ever joined a local community action to deal with an emergency?      | 2.35           | 1.65          | 1.89            | 7.936*         |
| Have you taken part in a community project?  | 2.38           | 2.08          | 2.31            | 1.209          |
| Have you helped organize new service in your area?   | 2.34           | 2.02          | 1.89            | 2.557          |
| If you disagree with what everyone else agreed on, would you feel free to speak out?               | 2.83           | 3.40          | 3.61            | 11.916*        |
| Do you think that multiculturalism makes life better?  | 2.87           | 2.22          | 2.81            | 8.923*         |
| Do you enjoy living among people of different lifestyles?  | 2.96           | 2.62          | 2.84            | 3.361          |

\*  $\rho \leq .001$

**Table 2: Rotated Factor Structure for Social Capital**

| <b>Factors</b>   | <b>Factor Loading</b> |
|--|-----------------------|
| <b><u>Factor 1. Participation in community activities</u></b>        |                       |
| Joining local community action to deal with emergency                | 0.756                 |
| Participating in community project                                   | 0.746                 |
| Being in a management/organizing committee of local group            | 0.711                 |
| Helping organize new service in the area                             | 0.699                 |
| Being an active member of local organization or club                 | 0.623                 |
| Helping out a local group as a volunteer                             | 0.488                 |
| <b><u>Factor 2. Proximity of network members</u></b>                 |                       |
| Attending local community events                                     | 0.715                 |
| Running into friends and acquaintances when shopping                 | 0.704                 |
| Going outside community to visit family                              | 0.649                 |
| Feeling that the local community is like home                        | 0.484                 |
| <b><u>Factor 3. Perceptions of contribution to society</u></b>       |                       |
| Feeling valued by society  | 0.825                 |
| Feeling satisfaction with what life meant                            | 0.799                 |
| Believing that helping others helps yourself                         | 0.544                 |
| <b><u>Factor 4. Attitude towards multiculturalism</u></b>            |                       |
| Enjoying living with people of different lifestyles                  | 0.864                 |
| Thinking that multiculturalism makes life better                     | 0.862                 |
| <b><u>Factor 5. Perceptions of safety and trust</u></b>              |                       |
| Feeling safe walking down ones street after dark                     | 0.783                 |
| Having a reputation of ones area being a safe place                  | 0.740                 |
| Agreeing that most people can be trusted                             | 0.542                 |
| <b><u>Factor 6. Access to and freedom to provide information</u></b> |                       |
| Knowing where to find information when making life decision          | 0.766                 |
| Feeling free to speak out when disagree with everyone else           | 0.525                 |

Extraction Method: Principal Components Analysis

## **ABSTRACT**

The purpose of this empirical study is to present results from a study of how entrepreneurs use networks, as well as describe the characteristics of these networks. A survey of 325 entrepreneurs from the KwaZulu-Natal province of South Africa was conducted.

Results from the ANOVA and t-tests reveal that there are significant differences between the ethnic groups on the following network variables: number of people the entrepreneur discussed the business with, how well the contacts are known, number of years contacts are known and how well contacts know each other. The results of the regression analysis showed that more than 30 percent of the variation of how well network of contacts are known (avecon) can be explained by ethnic group. Furthermore, more than 16 percent of the variation of number of years contacts are known (aveknow) can be explained by age and ethnic group variables.

## **INTRODUCTION**

The crucial importance of Small and Medium Enterprises (SME's) to the economic development of South Africa has been indicated by Lekota (1995: 11), and in searching for possible strategies to develop SME's, special focus needs to be given to ethnic groups that have been marginalised from active and meaningful participation in the South African economy. There is however, a lack of research on entrepreneurship in the South African context. Existing studies look into psychological traits (Van Vuuren & Boshoff, 1994; De Klerk, 1998) and demographic differences (Boshoff, Scholtz & Roodt, 1995). In recent enquiries, networking theory has been used as a mechanism for exploring the creation and development of new ventures. Looking at current investigations there have been no studies that looked into the characteristics of South African entrepreneurial networks as well as how these networks are used.

Researching entrepreneurship using the social networks perspective is imperative, as studying entrepreneurs' participation in networks highlights the importance of the social structure.

Social networks are crucial assets for business owners struggling to survive in competitive markets (Aldrich and Zimmer, 1986: 12-3; Aldrich, Elam & Reese, 1997). That entrepreneurship is largely a social activity and that entrepreneurs are largely social creatures suggests not only that academics need to continue research on the social networks of new ventures, but that aspiring entrepreneurs would benefit from learning the rudimentary tools of social network analysis (Burt, 1992).

### **KEY LITERATURE**

Ahwireng-Obeng and Piaray (1999: 78) assert that formal institutional factors exert a powerful negative influence on entrepreneurship in South Africa, and the historical and political system has served to promote an anti-entrepreneurial culture due to the dependency on, or control of, the population by the state which decreased the propensity for entrepreneurship (Allie & Human, 1998; Olomi, 1999: 164). In addition, Mbaku (2000) believes that the South African government failed to maintain an enabling environment for the development of indigenous entrepreneurship and the participation of Africans in national development (Iheduru, 1998).

Entrepreneurial activity does not occur in a vacuum. Instead, it is embedded in cultural and social contexts, and within webs of human networks that are both social and economic (Johannisson, 1990). In addition, Johannisson (1990: 4) affirms that entrepreneurs' personal networks are the "most significant resource of the firm". Empirical studies have illustrated that entrepreneurs use informal network contacts (family, friends, and business people) more than formal network contacts (bankers, accountants, and lawyers) as information sources (Aldrich, Rosen and Woodward, 1987: 158). An entrepreneur's personal network ties can expand the boundaries of rationality by creating and allowing access to knowledge and information. Once an entrepreneur has determined which relationships are crucial to the success of the new venture, most of the time is spent building, negotiating, and maintaining these relationships. This view that entrepreneurship is a social process, and that entrepreneurs act largely as social rather than solo players, should not lead researchers and educators to conclude that entrepreneurs' individual knowledge and skill is irrelevant to the success of a new venture (Byers et al., 1997). Rather, the essentially social nature of establishing connections and fruitful relationships with both insiders and outsiders means that the study of entrepreneurship should focus on social behaviour. This includes how people identify which relationships will be crucial to the success of their venture, and how they develop and maintain the relationships that enable their firm to obtain the resources needed for their firm to survive and grow. Granovetter (1973: 1367) claims that weak ties act as "bridges" to information sources not necessarily contained within an entrepreneur's immediate (strong-tie) network. Since an individual does not interact with weak ties regularly, it is likely that weak ties provide more unique information than strong ties.

### **RESEARCH METHODOLOGY**

The purpose of this paper is to present results from a study of the role of networking in different ethnic entrepreneur group in South Africa. The aim is to make intelligible how and why different group use networking in different ways to acquire and organise capital, within the specific socio-economic and institutional context of South Africa.

Data for the analysis was collected from more than 300 entrepreneurs in Durban, the largest city in the province of KwaZulu-Natal, South Africa. Entrepreneurs were requested to fill in a structured survey instrument to ensure reliability and validity in responses obtained. The sample was selected from entrepreneurs from the three dominant ethnic groups in the region: African, Indian and European. The three ethnic groups chosen for this study will contribute more to our understanding of how networking in entrepreneurs is conducted within a developing country.

The sample was selected largely by personal contacts and referrals and introductions by those interviewed. Given that a great deal of ethnic businesses are still operated in areas dominated by specific ethnic groups, research assistants from the same ethnic group as the respondents' were used. This methodology was utilised by Ram (1991) and Basu and Goswami (1999) in studies conducted in England, Light and Bonacich (1988) in studies in the US, whereby having interviewers with the same ethnic background led to more access and acceptance by the entrepreneurs.

Comparison of means using analysis of variance (ANOVA) and t-tests of several networking variables were conducted to determine significant differences of entrepreneurs based on different personal characteristics. Furthermore, a stepwise multiple regression analysis was conducted to determine the best demographic predictors of respondent's scores on several network variables. Network Activity is measured by the size of the network (number of contacts the entrepreneur discusses the business with) and how actively entrepreneurs use these contacts (hours spent developing and maintaining contacts & percent of time spent networking). Network Density is measured by how well the entrepreneur knows each contact's network, the number of years the entrepreneur has known the contacts and how well the contacts know each other.

## **RESULTS AND DISCUSSION**

In this section, a profile of some of the characteristics of the entrepreneur, their utilisation of networks, the extent of their networking activity, density and diversity, and a comparison of the three ethnic groups of key networking variables are presented.

### **Characteristics of the entrepreneur**

The sample size was 325, of which 34.2 percent (N=111) were African entrepreneurs, 37.2 percent (N=121) were Indian entrepreneurs, and 27.7 percent (N=90) were European with 1 percent (N=3) classified as other. Several descriptive characteristics are presented in table 1. In order to test if there are significant differences between African, Indian and European entrepreneurs on the demographic data collected, a Chi-square ( $\chi^2$ ) test was performed.

At the  $p = .001$  level, there were significant differences between the three groups on gender. The majority of the entrepreneurs in the three ethnic groups were male, except for the European group. Less than 22 percent of the Indian respondents, 41.4 percent of the African, and 51.1 percent of the European entrepreneurs were female.

The  $\chi^2$  results show that at  $p = .001$ , there are significant differences in the ages between the entrepreneurs from the three ethnic groups. It is apparent that that the African ethnic entrepreneurs are younger, with the majority (63%) below the age of 40. In contrast, 71.7

percent of the Indian and 85.8 percent of the European respondents are over the age of 40.

With regards to education, the results show that at the  $\rho = .05$  level, there were significant differences between the ethnic groups on education. In the three groups, the majority had completed twelve years of schooling (African 87.2%; Indian 80.8%; European 91.1%). A higher percentage of Indians (53.3%) had finished 12<sup>th</sup> grade, although more Africans (45.9%) had a degree or diploma.

Looking at the marital status of the entrepreneurs, the  $\chi^2$  results also indicate significant differences between the three ethnic groups. The majority of entrepreneurs in all three ethnic groups are married, with 55.7 percent of the Africans, 80.8 percent of the Indians, and 66.7 percent of the Europeans being married. The  $\chi^2$  results show that for all ethnic groups, very few of the respondents had parents who were entrepreneurs. However, at the  $\rho = .001$  level, there were significant differences between the three groups on whether they had close relatives who were entrepreneurs. Only 24.3 percent of African entrepreneurs, while 68.6 percent of the Indian group, and 66.7% of the European sample had indicated that they had a close relative who was an entrepreneur.

### **Networking variables**

In table 1, differences in activity and size of networks of South African entrepreneurs classified according to ethnic group of the entrepreneur are presented. In response to the question “with how many people did you discuss your business?”, the mean score for African entrepreneurs was 4.50, whereas the score for the Indian group was 11.70, and 10.24 for the European group.

-----  
Table 1 Here  
-----

At the  $\rho = .05$  level, there was a significant difference between the three groups with the Indian and European entrepreneurs on average discussing their business with almost three times more people than their African counterparts.

The scores in response to the question “how many hours per week developing contacts?” gave very similar results with all the groups spending about six hours per week developing contacts. The responses to the question “how many hours per week maintaining contacts?” again revealed similar results, with the three groups spending between 6.33 – 7.74 hours maintaining their contacts. The ANOVA results indicate no significant differences between the three ethnic groups on the number of hours spent developing and maintaining contacts.

Table 1 presents three variables measuring different aspects of network density: how well the entrepreneur knows his contacts’ network, the number of years the entrepreneur has known the contacts and how well the contacts know each other. The table also includes the results that indicate how these contacts were met. At  $\rho \leq .001$ , the ANOVA results show that there are significant differences between ethnic groups on the three variables measuring network density. European entrepreneurs know their contacts better and have known their contacts for a longer period of time compared to their Indian and African counterparts. Members of the European entrepreneurs’ network also knew each other better compared to the Indian and

African entrepreneurs'. Overall, Indian respondents had better results than Africans when it comes to all three network density variables.

In order to determine whether the demographic data (from table 1) can predict the respondent's scores on the network variables, a stepwise multiple regression analysis was conducted. The scores on network activity (number of people the entrepreneur has discussed his business with, number of hours per week developing contacts, number of hours per week maintaining contacts) served as the dependent variables. The entrepreneur's demographic data were used as independent variables (gender, age, education, marital status and entrepreneur's in the family).

Of the three regressions performed on network activity variables, the variance of only one variable was found significantly explained by demographic variables. The findings of the multiple regression analysis with "how many people did you discuss your business" (NUMPEO) as the dependent variable (refer to table 2). The best solutions for the NUMPEO dependent variable, in terms of  $R^2$ , significance of t and significance of F were obtained with model 2. Only about 9 percent of the variation of NUMPEO was explained by close relative and age variables with  $R^2=9.2$  percent. Analysis of variance indicated that  $F=11.120$ ,  $\rho=.000$  for the model. The t value of the coefficient for close relative was significant at the 1 percent level ( $t=3.961$ ,  $\rho=.000$ ), and significant at the 5 percent level for age with  $t=2.173$ ,  $\rho=.031$  respectively.

-----  
Table 2 Here  
-----

Of the three regressions performed on network density variables, the variance of all three variable was found significantly explained by demographic variables. Table 3 illustrates the findings of the multiple regression analysis with "how well network of contacts are known" (AVECON) as the dependent variable.

The best solutions for the AVECON dependent variable, in terms of  $R^2$ , significance of t and significance of F were obtained with model 1. About 32 percent of the variation of AVECON was explained by ethnic group with  $R^2=32.1$  percent. Analysis of variance indicated that  $F=100.693$ ,  $\rho=.000$  for the model. The t value of the coefficient for ethnic group was significant at the 1 percent level ( $t=10.035.961$ ,  $\rho=.000$ ).

-----  
Table 3 Here  
-----

Table 4 illustrates the findings of the multiple regression analysis with "number of years contact is known" (AVEKNOW) as the dependent variable. The best solutions for the AVEKNOW dependent variable, in terms of  $R^2$ , significance of t and significance of F were obtained with model 2 (table 2). Approximately 16 percent of the variation of AVEKNOW was explained by age and ethnic group variables with  $R^2=16.2$  percent. Analysis of variance indicated that  $F=23.538$ ,  $\rho=.000$  for the model. The t value of the coefficient for age was significant at the 1 percent level ( $t=4.174$ ,  $\rho=.000$ ), and significant at the 1 percent level for

ethnic group with  $t=3.892$ ,  $p=.001$  respectively.

## CONCLUSIONS

This study looks into the different network characteristics of South African entrepreneurs. Three features of networks were used: activity, density and diversity. Overall findings indicate that South African entrepreneurs are not maximising the use of their networks.

Network activity looks into the size of the network and the amount of time spent developing and maintaining networks. The regression results also reveal that age and having close relatives that are entrepreneurs can explain the variance in the number of people the entrepreneur discusses the business.

Density refers to how tightly connected the persons in a network are to each other. The regression results also indicate that age and ethnic group are significant variables for explaining variances in the number of years that the entrepreneur has know his contacts.

A network that is highly dense means that persons in the network know each other and to a large extent may share redundant or overlapping information. The results of the regression show that ethnic group can significantly explain variations in how well the entrepreneur knows his contacts. Upon further investigation using t-tests and ANOVAs, results show that when these three network density variables are classified according to ethnic group, significant differences emerge. European entrepreneurs know their contacts better, longer and their contacts know each other better compared to Indian and African entrepreneurs. The regression results suggest that age is a significant explanatory variable for how well contacts know each other.

The density of the entrepreneur's network is also indicated by how his contacts were met. Obviously, referrals would indicate that the entrepreneur's existing contacts help him generate other possible sources of information or complementary assets. Regardless of ethnic group, most entrepreneurs' existing contacts were met through their own effort.

To conclude, this paper has attempted to add to our understanding of ethnic entrepreneurs in South Africa. It is widely accepted that entrepreneurship is a social activity, embedded in a social context. The unique political situation in South Africa which rendered the majority group marginal, raises questions over whether theories of marginality in ethnicity which have been developed in the study of minority groups, may be relevant to a marginalised majority group. Furthermore, one needs to question whether theories of ethnic business, based on immigrant groups, apply to ethnic groups that are indigenous to the country, such as the African ethnic group.

# **ENTREPRENEURSHIP IN BIOTECHNOLOGY INDUSTRY - A CASE STUDY OF SWEDEN**

Wali I. Mondal  
Juan España  
National University

## **Abstract**

Sweden is the leader in per capita outlays on research and development among developed countries. This fact combined with the country's unique law regarding grant of patent rights has made Sweden the leader of biotechnology inventions. Swedish law grants university teachers, rather than the universities employing them, the patent rights to their inventions. Some believe that the 1995 merger of Swedish drug company Pharmacia and the American drug company Upjohn as well as the merger of Astra with the British company Zeneca sparked the growth of biotechnology research in Sweden by displacing thousands of Swedes from the merged company. The paper analyzes Swedish entrepreneurial activities in the biotechnology industry using Schumpeter's five-factor model of entrepreneurship and draws policy implications for entrepreneurship in relation to patent law.

## **Introduction**

Pharmacia & Upjohn Inc was formed through a merger of Pharmacia AB and The Upjohn Company and began operating in November 1995. In December, 1999 Monsanto, the American drugs group famous for its research into genetically modified foods, merged with Pharmacia & Upjohn Inc. The merger of Monsanto with Pharmacia and Upjohn, Inc. created a new company, the Upjohn Corporation, with annual sales of \$17 billion, making it the eighth largest pharmaceutical company in the world. Later in 2003, Upjohn Corporation was acquired by Pfizer which became the world's largest pharmaceutical company. The decade of the 1990s also witnessed the merger of Swedish pharmaceutical company Astra with the British drug company Zeneca. Many analysts believe the merger of the culturally diverse companies created strong synergies in the biotechnology industry from a strategy perspective; however, the new companies displaced a significant number of scientists. The displaced scientists, aided by the Swedish law on patents and innovations accounted for a high growth rate of biotechnology innovations in Sweden. The purpose of this paper is to analyze Swedish entrepreneurship in the biotechnology industry using Schumpeter's five-factor model.

## **Swedish Patent Law**

According to Swedish Patent Act, "Any person who has made an invention susceptible of industrial application, or his successor in title, is entitled to apply for and to obtain a patent... For the purposes of the international preliminary examination, a claimed invention shall be considered industrially applicable if, according to its nature, it can be made or used (in a technological sense) in any kind of industry. "Industry" shall be understood in its broadest sense, as in the Paris Convention for the Protection of Industrial Property." (Department of Justice, Sweden. Adapted from <http://listbox.wipo.int/wilma/scp-orum/2001/msg00012.html>)

As Boklund (2003) mentions, for a long time, Swedish biotechnology industry was synonymous with two large pharmaceutical companies, Astra and Pharmacia; however, the emergence of many small and innovative biotechnology companies has made Sweden the leader in biotechnology inventions.

Historically, Sweden has been a leader in the biotechnology industry. During the 1940s, a number of foreign pharmaceutical companies began launching their own products on the Swedish market, thus pushing Sweden's pharmaceutical corporations to invest in research and development in biotechnology. Another factor that helped the growth of Swedish biotechnology industry was the good cooperation that the scientific community of Sweden enjoyed between corporations, universities and the healthcare sector. This was further aided by a well functioning system of clinical testing which meant that drugs could be tested faster and introduced onto the market more quickly. The patent law also helped the chemical industry, allowing the production of medical instruments to pick up speed and further contributing to the development of the pharmaceutical corporations.

### **Mergers and Growth of New Biotech Companies**

During the 1990s, when Astra and Pharmacia merged with foreign companies, a significant number of highly qualified workers of the two Swedish pharmaceutical firms were laid off. Of the laid off workers, between 10 and 20 per cent possessed doctorate degrees (Boklund, 2003). These scientists started their own venture and obtained patents for their inventions. Very soon, the larger pharmaceutical companies found it advantageous to outsource their research to new small biotech companies where the environment for research and development conducted by small teams is more creative. The 1990s also witnessed a rapid growth of the venture capital sector in Sweden in parallel with the diversification of the biotech industry contributing further to the growth of the biotech industry. By 2003, the total number of biotech companies in Sweden rose to over 200, making Sweden's biotech industry the fourth largest in Europe. Relative to gross domestic product, taking into account its size, Sweden has arguably the most successful biotech industry in the world. Relative to its population, Sweden is one of the top three countries in the world in terms of biotechnology research and publication.

### **The Model**

The emergence of Sweden as the world leader in biotechnology inventions can be analyzed using the model of entrepreneurship developed by Schumpeter. Although the literature on entrepreneurship dates back to the Mercantilist era, Schumpeter is the first economist who distinguished between an entrepreneur and a capitalist (Schumpeter, 1939, 1950). According to him, assumption of risk involving innovation is the role of the entrepreneur, while assumption of risk involving potential for profit is the role of a capitalist. Both an entrepreneur and a capitalist undertake risk; but their *domains* are separate. Individuals who own business and take risk with their capital in pursuit of profit, but do not innovate, are capitalists. There are individuals who take risk by introducing a new product, adopting a new production process, creating new markets, introducing new technology or creating a new economic organization. Schumpeter referred to these individuals as "entrepreneurs" who belong to a "distinct sociological class". According to him, the process of discovery and innovation modifies the past and creates new

opportunities for the creation of wealth in the future. This is what Schumpeter described as the process of “creative destruction”.

According to Schumpeter, “the function of entrepreneur is to reform or revolutionize the pattern of production by exploiting an innovation or, more generally, an untried technological possibility for producing a new commodity or producing an old one in a new way, by opening up a new source of supply of materials or a new outlet for products, by reorganizing an industry...” (Schumpeter, 1950, 1939). He went on to attribute innovation as the business activity that brings about a new production function as a result of one or more of the following five economic activities:

1. introduction of a new good
2. adoption of new inputs to produce a new good or the previously produced good
3. introduction of new technology
4. opening of a new market; and
5. creating a new economic organization.

Figure 1 links innovation to Schumpeter’s five elements of entrepreneurship.

[Insert Figure 1 about here].

We discuss briefly the five economic activities of Schumpeter’s model as they apply to the inventions in biotechnology sector in Sweden.

**Introduction of a New Good:** The pharmaceutical companies of Sweden have developed and introduced many new products in the market during the past two decades. Notable among these are the COX-2 Specific Inhibitor, valdecoxib tablets and launching of 17 new drugs after the merger of Pharmacia with Upjohn. Additionally, on the basis of population per capita, the smaller pharmaceutical companies of Sweden with less than 500 employees developed and introduced the highest number of biotech products in the market after the merger of Astra and Pharmacia during the 1990s.

**Adoption of New Inputs to Produce a New Good or the Previously Produced Good:** The merger of Monsanto with Pharmacia Upjohn Corporation created the Pharmacia Corporation. This merger created opportunities for the Pharmacia Corporation to adopt new inputs previously unique to Monsanto Corporation.

**Introduction of New Technology:** The Mergers created synergies for the Pharmacia Corporation allowing for an investment of \$2 billion in research and development for the new corporation. A portion of this fund was outsourced to smaller companies which used the enhanced resources to develop new technology.

**Opening of a New Market:** The biotech products developed in Sweden are sold worldwide.

**Creating a New Economic Organization:** As noted, the mergers created global economic organizations, which were much bigger in size.

## **Summary and Conclusions**

Sweden is the leader in per capita outlays on research and development among developed countries. This fact combined with the country's unique law regarding grant of patent rights has made Sweden the leader of biotechnology inventions. The 1995 merger of Swedish drug company Pharmacia and the American drug company Upjohn and the merger of Astra with the British company Zeneca sparked the growth of biotechnology research in Sweden by displacing thousands of Swedes from the merged company. On the basis of population per capita, Sweden has the most biotech-intensive industry in the world.

The post-merger biotech sector of Sweden combined with the country's unique patent law lends itself to the Schumpeterian model of entrepreneurship. In this model, the biotech inventions play the pivotal role in changing the production function of the biotech industry through introduction of a new good, adoption of new inputs to produce a new good or the previously produced good, introduction of new technology, opening of a new market; and creating a new economic organization.

**Abstract**

E-business and information technologies in general offer potentially powerful means to boost the development of SMEs in the context of today's global economy. Many e-business and IT-based regional development initiatives have been put forth by governments around the world, including virtual communities, local or regional portals, and e-marketplaces. Starting with a four-step model of local and regional development (LRD) initiatives, a survey and two focus groups allowed us to characterize the needs of manufacturing and technological SMEs in the Mauricie region of the province of Quebec, Canada. On this basis, promising initiatives for the development of SMEs in a LRD context are identified, including the integration of tools and advanced business practices within a regional e-business appropriation portal. A prototype of such a portal is presented in conclusion.

**Résumé**

Dans un contexte d'économie mondiale, les technologies de l'information (TI) et les affaires électroniques (AÉ) sont potentiellement de puissants catalyseurs de développement des PME, ainsi que des communautés locales et régionales. Plusieurs initiatives concernant les TI et les AÉ ont été entreprises de par le monde, incluant des collectivités numérisées à base de « portails » locaux ou régionaux ou encore de places de marchés électroniques. Partant d'un modèle en quatre étapes caractérisant les initiatives de développement local et régional (DLR) par les AÉ, une enquête et deux groupes de discussion ont permis de caractériser les besoins de PME manufacturières et technologiques d'une région canadienne, soit la Mauricie au Québec. Sur cette base, des initiatives prometteuses pour le développement des PME dans un contexte de DLR sont identifiées, incluant l'intégration d'outils et de pratiques d'affaires avancées au sein d'un portail d'appropriation régionale des AÉ, dont un prototype est présenté en guise de conclusion.

## **E-business and the development of SMEs: Promising initiatives in the context of local and regional development**

### **1. Introduction and issues**

For the past few years, information technology (IT) has been accessible to people throughout the world; IT seems to have done away with distance and time (Cairncross, 1997). This phenomenon not only affects the individual, but enterprises of all sizes and sectors as well. Among the advantages in adopting IT, that of improving competitiveness can appear to be one of the more important because of the lowering of geographical and temporal barriers. Small and medium-sized enterprises (SMEs) adopt IT hope, among other things, to increase their market share and growth, and to outdistance their competitors (Raymond and Blili, 1998). However, can improving their competitiveness influence local and regional development? Can local and regional development have a significant effect on the economy of a state and, in the limit, a nation? This subject raises several questions, being a vast area, complex and undergoing continuous change. And above all, the challenge between IT and regional development is that the rate of change is not the same for both; it is as rapid for IT as it is slow for local and regional development (Julien, 1997).

This research presents the study of the adoption of e-business and IT in general by SMEs. The main objective of this project is to understand this phenomenon and the process of stimulating local and regional development by an adequate support for SMEs. In the next section of this article, we will discuss the environmental mutations and IT in the new economy. An inventory of the principal obstacles as well as initiatives will be presented. The methodological considerations of this research will be discussed with the Mauricie region as a basis. The results of the investigation will be presented by identifying the principal solutions that emerge from this research, and suggestions for further work will be discussed in conclusion.

### **2. Environmental mutations and IT**

SMEs make up more than half the total number of enterprises in Canada and more than 90% in one of its provinces, Quebec. These enterprises now play a dominant role, but must always share the market with large enterprises (LEs). Both have to deal with the same realities of international competition, but do not have the same means at their disposal, whether financial or technical. In addition to competing with LEs, SMEs must often deal with them as business partners. New forms of inter-organizational relations, such as the introduction of networks, the creation of partnerships, or the establishment of strategic alliances are among the measures taken in order to adapt to the new environmental realities.

Local and regional development has also undergone transformations following mutations of the enterprises. The small enterprises have scattered over the territory, bringing with them their economic and social fallout. Regions that must avoid dependence on a single enterprise or on a single industry find that SMEs are a solution to their problem.

In general, IT and e-business<sup>1</sup> can constitute powerful vectors of development at the local and regional levels. These technologies can in this way play an innovative role in economic activities, a role in which time and distance are redefined in accordance with the new standards (Jeffcoate et al., 2002; Charlton et al., 1998). The appropriation of IT by SMEs can maintain or improve their market share: the abolition of frontiers permits them to extend their zone of influence beyond their usual territory, or improve their quality by the time or the fluidity of the sequence of the operations of supply, production, and shipping of goods (Bigras and G  linas, 1998). E-business can constitute a global and worldwide network of links between partner enterprises. This network brings to these enterprises a competitive advantage and improves their performance. However, SMEs will need to acquire new skills and adapt their business models in the light of their new electronic activities (C  t  , Sabourin and V  zina, 2004).

One of the competitive advantages of SMEs is based on continuous and diffuse innovation, that is, they must build and manage their knowledge (or distinctive skills). In this way, these enterprises will be characterized by a more "open" and "learning" management and organization. Their technological capacity must be continuously updated by training, by the accumulation of rich information, and by the transformation of this information. These learning SMEs utilize knowledge to create added value (Wright et al., 1995), which has become more than necessary for regions in the present context of the new economy (Pol  se and Shearmur, 2002). In order for these regional SMEs to be allowed to develop, there must be a dynamic milieu, based on a common culture of norms, knowledge, and know-how, that stimulates the entrepreneurial contagion as well as a culture of networking by the enterprises and other stakeholders in local and regional development. Figure 1 presents a schematic of this innovating regional SME.

### Figure 1

Networking is an essential activity for SMEs desiring to be in a position to innovate, since rich and varied information, which is the source of innovation, comes precisely from outside the enterprise (Julien et al., 2003). Thus, networks are based on the detection and the sharing of rich information, allowing learning and innovation as well as the creation of a culture of regional cooperation and a feeling of belonging. The purpose of electronic networks remains the same as that of the traditional ones, but IT can facilitate the emergence of networks in the regions by serving as a physical support to the exchange of rich information. This would increase the effectiveness of these networks. The netMetal<sup>2</sup> portal is a good example of an electronic network aimed at establishing a culture of collaboration between business partners while at the same time having the objective of increasing their respective performance (Raymond, Talbot and V  zina, 2002).

St-Pierre et al. (2003) have categorized the regional SMEs into four business models in two development dimensions: innovation and internationalization. These business models, shown in Figure 2, are: first, "innovating" SMEs, whose development is centred on innovation (new

---

<sup>1</sup> The "e-business" expression electronic business is utilized in a more inclusive sense than "e-commerce". It includes aspects that are not only informational and transactional (electronic commerce), but also business relational (Greenstein and Vasarhelyi, 2002: 2).

<sup>2</sup> NetMetal ([www.netmetal.net](http://www.netmetal.net)) offers its members in the metallurgical industry various tools that allow them to enhance their visibility and develop new markets.

products and services, new production processes) aimed at cost reduction, increased flexibility, and the strengthening of bonds with business partners (customers, suppliers, prime contractors, etc.); second, “exporting” SMEs, whose development is centred on internationalization; third, “world-class” SMEs, whose development is centred as much on innovation as on internationalization (these SMEs are characterized by their exemplary practices and their open leadership); and fourth, "local" SMEs, whose development is centred on stability and profitability (these SMEs are characterized by their limited desire for growth and their wish to restrict their market/range of products; in addition, their management generally is less educated and less apt to devote time to seeking out rich information).

It is in this fourth group that the majority of the regional SMEs find themselves. According to an approximation based on research carried out at the Research Institute on SMEs, about 60% of SMEs are "local" in terms of their business model (Raymond and St-Pierre, 2003). Moreover, this is the model whose definition is closest to the characteristics peculiar to SMEs, such as small size, centralized management, low degree of specialization, an intuitive or informal strategy, and a system of internal and external information that is uncomplicated or little organized (Julien, 1997).

According to the specificities of each of the models presented in Figure 2, IT can offer support and business solutions to the SMEs that wish to centre their development on innovation and/or on internationalization. For "local" SMEs, access to the Internet could help them find information, allowing them to improve a product or process, for example.

### **Figure 2**

Across the industrialized world over the past few years, several initiatives involving IT and e-business have been put forward in order to support and accelerate local and regional development (EuroCom, 2002) in spite of the economic slowdown that has recently hit the IT sector. The world over, enterprises and governments have taken advantage of the Internet to improve their productivity. Thus, governments of some countries have advanced several projects in order to follow suit, while in other countries projects have emerged from the grassroots: various stakeholders or socioeconomic partners have encouraged small enterprises to adopt IT and e-business. Several local or regional electronic portals have seen the light of day, and electronic markets have been proposed as well (see the Appendix for examples in the United Kingdom and in France).

A study on the impact of the Internet carried out by the *Canadian e-Business Initiative* (CeBI, 2003) compares Canada favourably to the United States and the European Union on matters of e-business adoption by SMEs. Thus, Canada finds itself first in certain key areas like e-government. Half of Canadian SMEs (50.2%) utilize e-business or are in the process of setting it up, while 20.3% plan to adopt it over the next three years. However, more than one fourth of the SMEs (28.4%) have no intention of adopting these technologies, these firms thus running the risk of being kept out of integrated global supply chains. Maintaining the competitiveness of the Canadian economy is a matter of accelerated adoption by SMEs of these technologies (Jopko et al., 2001). Thus, it is important to clearly understand the situation of SMEs in order to provide them with adequate support in their growth and economic development, and to offer them programs designed to promote their adoption of IT in general, and e-business in particular. Why

do many SMEs not adopt e-business? As a consequence, are there promising e-business adoption initiatives that can provide for the growth and development of SMEs in the context of local and regional development.

### **3. Obstacles to the adoption of e-business: initiatives and programs**

A number of studies have identified the obstacles that the SMEs encounter when they wish to adopt e-business (e.g., Bégin et al., 2000; ICCE, 2003; Mora-Monge et al., 2001; Poussart, 2002; TableRonde, 2001; Terry, 1999). In short, the obstacles most often noted involved security and confidentiality, the absence of an adequate business model and of a business plan, a negative perception of e-business technologies among owner-managers, the weak enthusiasm of customers and suppliers to utilize e-business, the legal questions, the inaccessibility of a wideband network infrastructure, the lack of e-business skills and know-how, little or no qualified human resources as well as the lack of appropriate technologies, the high cost and the uncertainty in the return on investment, access to financing, the high level of competition, a product or a service not adapted to e-business, an inadequate organizational structure, the complexity of product delivery as well as all the cultural and linguistic barriers that can be added to this list.

The adoption of e-business by SMEs in any region of the world thus constitutes a sizeable challenge. A variety of programs and initiatives have been introduced in order to overcome these obstacles, as much for the SMEs as for the stakeholders of local and regional development. These initiatives were analyzed and grouped according to different criteria. Clearly, certain initiatives were difficult to categorize explicitly given their polymorphous character. Examples of initiatives that captured our attention stem mainly from governmental organizations, such as in the United Kingdom with portals for SMEs such as Merseyworld ([www.merseyworld.com](http://www.merseyworld.com)), or in France with the Nord-Pas-de-Calais region ([www.decllic.net](http://www.decllic.net)). Figure 2 sets out initiatives brought to light in the preceding summary, using the four SME business models previously described. Thus, certain programs like *Trade UK* or *First Steps Workshop* are intended more for "exporting" SME. Others such as *Netherlands goes Digital* are aimed at "local" SMEs., whereas "exporting" SMEs find valuable assistance thanks to efforts such *Exportool* and *Passeport-Export*..

Our objective is not to analyze the initiatives in terms of their success or lack of it, but rather to highlight the importance that the various political and economic stakeholders grant them. Consequently, a new model was developed that presents a logical progression to follow by SMEs having at first little understanding of IT and e-business, leading eventually to a complete integration of all business possibilities made available by these technologies. This model also takes into account the factors that influence the development of regional SMEs, as previously identified in Figure 1.

This progression is made up of four main stages that characterize previous and current initiatives of local and regional development through e-business:

1. Alert enterprises to networking and to e-business; it is a matter of helping SMEs discover the advantages of e-business through information. Public organizations develop or introduce policies intended for the economic stakeholders of the region. Such initiatives are of a very general nature, since they aim "very wide."

2. Develop an environment favourable to the utilization of IT when enterprises are created. This involves the introduction of programs to stimulate the economy through the development of new enterprises. The Crossroads of the New Economy (CNE) program is one example. Once again, it is a matter of general initiatives targeting all enterprises.
3. Assist the development of enterprises and their projects through programs of support, financial help, etc.
4. Develop networking with the idea of making it possible for enterprises to do business among themselves. This initiative is at once individual and collective. Indeed, the needs of networking are peculiar to each enterprise.

---

**Figure 3**

---

The outcome of the application of this model is a contribution to local and regional development. Indeed, for a given region or territory (the Mauricie region of Quebec, in our case), the more SMEs integrate IT-enabled processes within the scope of their business activities, and the more they can contribute to the economic development of the region.

#### **4. Research methodology**

The unit of analysis is the Quebec SME, and the sample consists of SMEs of the Mauricie region (Moreau et al., 2004). The region is especially dependent on the pulp and paper industry, but this sector has been slowing down for about 15 years. In addition, qualified human resources are not available in certain sectors, and the entrepreneurial culture is weak when compared to other Quebec regions such as the Beauce region (Julien, 1997). However, for the past two years, the Mauricie region has been experiencing an economic restructuring that should result in the creation of several SMEs, including some in high technology. Nonetheless, the evolution of this region, both cultural and social, takes place at a slow pace. The Mauricie region is not a "silicon valley", but perhaps IT and e-business can provide it advantages, and thus support it in its local and regional development.

Our approach, an exploratory field study, was carried out by means of a telephone survey. Two focus groups were also conducted. The principal objective of the study is the analysis of the needs of SMEs so as to facilitate adoption of IT and e-business in a perspective of local and regional development. The survey included 34 questions dealing with networks and partnerships, technologies and e-business practices, programs for developing e-business and incentive measures for SMEs, and the development of the Mauricie region. Given the exhaustive nature of the questionnaire (duration of the interview between 30 and 45 minutes), a small but representative sample of 56 SMEs was selected in all sectors of activity as identified and segmented by Statistics Canada. Among these respondents, 31 SMEs were located in an urban environment versus 25 in a rural environment, with 13 in the manufacturing/technology sector and the 42 others in trade and distribution. As far as the two focus groups are concerned, the first one was made up of 13 stakeholders in the region's development (associated to different public and semi-public agencies and organizations), and whose role is directly linked to SMEs. The second group was made up of 12 entrepreneurs from different industries.

## **5. Analysis of the results**

The results of our survey and of the two focus groups will be presented in three parts: networking, the region's infrastructure, and the adoption of e-business by the SMEs.

### **5.1 Networking in the Mauricie region**

As far as networking between SMEs of the Mauricie region is concerned, most have no collaborative relations between them. The SMEs do not perceive the benefits that they can draw from networking. Yet, 65% of these SMEs are members of an association, a group, or a social network. On the other hand, little time is devoted to these networks; entrepreneurs generally consider that these groupings cannot help them settle their problems. Moreover, 74% of SMEs do not wish to join a new network, whether electronic or not.

Entrepreneurs believe that IT, and networks supported by IT, are useful only for certain sectors and for very specific products and services. Moreover, they believe that networks and partnerships should be used to attract new enterprises to the region. In addition, they admit that only specific projects can be carried out by networking SMEs. They are well aware that IT can reduce problems involving distance, but face to face communication remains one of the most crucial activities in business for them. Only 7% of the SMEs utilize one or several portals available to them, whereas 20% do business with their suppliers by this means of electronic communication. Generally, they are uncomfortable with the idea of sharing information by means of an electronic network.

There is still no established business practice concerning the collection of information and its management on the Internet. Moreover, there does not yet exist well-known "success stories" on the use of e-business by the milieu that would have a positive effect on other SMEs. The managers mainly relate setbacks related to IT adoption. Thus, the SMEs of the Mauricie region have not yet adopted new network practices and new business practices. They experience a lack of training concerning the new IT. Returning to Figure 1, these factors of training, information, and networking constitute a very important obstacle to the birth of the new economy in the region.

As a whole, the region is characterized by a weak networking culture. These results confirm those of Julien et al. (2001). In addition, the support for the SMEs by the stakeholders in local and regional development is fragmentary and lacks coordination. Few of these stakeholders employ IT to establish or facilitate networking activities between themselves and the SMEs of the region.

### **5.2 Technological and social infrastructure of the Mauricie region**

First, entrepreneurs and other stakeholders in local and regional development agree on the fact that one of the major obstacles to the adoption of e-business is access to a wideband (high-speed) Internet connection. At the present time, this access is possible on only a small portion of the territory of the Mauricie region (urban SMEs). However, a collective project of public and private participants is setting up this infrastructure in the region. The enthusiasm of regional SMEs for this project has not yet been confirmed.

Second, other technological infrastructure needs, such as service providers for electronic commerce Web sites, have been voiced. Other entrepreneurs speak of a shortage of qualified human resources specialized in IT and e-business. Only a third of SMEs in the region have access to a high-speed Internet connection. Essentially, an insufficient technological infrastructure characterises the Mauricie region. Local and regional IT service providers in regard to Web sites and e-business applications are rather rare and under-staffed.

### **5.3 Adoption of e-business by the SMEs in the Mauricie region**

In our sample of 56 SMEs, 29% utilize the electronic data interchange (EDI) with at least one supplier. The Internet is utilized by 57% of the SMEs to exchange information with suppliers, 71% with clients, 49% with financial institutions, and 44% with at least one level of government. Whereas only 11% of the SMEs are familiar with a government program to assist them in adopting e-business or e-commerce tools. Note that the technologies most often utilized to communicate with suppliers, clients, and governments remain the telephone and the fax machine.

Web sites are 95% informational, while 42% allow visitors to order on line and 21% offer the possibility of on-line payment. Interestingly, 89% of the SMEs know that the Internet provides economic and social benefits to enterprises in general, but only 62% of them believe that this would be true in their case. Many entrepreneurs do not see the urgency in adopting e-business tools because they consider the Internet as not being secure enough and as intruding too much in the privacy of individuals and the confidentiality of enterprises. Several have a negative opinion of e-business because of Internet "horror stories" experienced by certain enterprises and reported in the media.

Another important element for entrepreneurs is that they sense a lack of training and understanding of e-business practices and tools. They doubt that these tools are very appropriate for their own products or services. Moreover, they feel unable to face a major growth in sales because they lack the added investment capacity. Several wonder about the return on investment of an e-business project. They are also conscious of the fact that adopting e-business will force them to reengineer their business processes, and therefore are not necessarily ready for such a leap.

In short, SMEs in the Mauricie region are characterized by weak integration of IT and e-business in their business models. Other factors that have negative effects include the fact that few SMEs in the region have experienced success in using e-business (few "success stories"), limited access to a high-speed Internet connection, insufficient training and knowledge about IT and e-business, and the absence of an IT culture and a networking tradition among SMEs.

## **6. Promising initiatives and conclusion**

One way of promoting and supporting local and regional development in the Mauricie region is to introduce initial conditions that would help the SMEs become more productive and competitive in the new knowledge-based economy. The results of the survey and of the focus groups show that the adoption of IT and e-business by SMEs of the Mauricie region will not happen overnight. These enterprises will not be able to join the new economy if they do not acquire the necessary means. These means can be summarized under three central themes:

networking, technological and human resource infrastructure, and training in IT and in e-business.

First, an improvement in networking should allow SMEs to share information and knowledge. They would cooperate and create collective resources and skills. As for the other stakeholders in local and regional development such as public agencies, they would collaborate in a more effective and integrated manner in order to better respond to the needs of SMEs. Thus, they will contribute to the creation of a regional dynamism that will make it possible to promote development and entrepreneurship in the region.

Second, an improved technological and human resource infrastructure should permit SMEs easy access to a high-speed Internet network anywhere in the region. The stakeholders in local and regional development will collaborate with the management of SMEs in order to attract qualified human resources, i.e., individual that have specialized IT and e-business expertise. Moreover, these stakeholders would imagine ways of attracting and convincing entrepreneurs and employees to settle in the Mauricie region.

Third, training in IT and in e-business should allow entrepreneurs to adopt a positive attitude, open and proactive, to the integration of IT in their business processes. For this to happen, varied training and information activities via networks (including e-learning) would allow entrepreneurs to acquire a better understanding of the business practices in the new economy. Such training and information activities would include strategic and technological dimensions of e-business, including new business models and infrastructures. The SMEs would have easy access to adequate means of communication (including e-conferencing and e-collaboration) and rich information (including e-business intelligence). In addition, they would be able to maintain their existing markets and be favourably positioned to compete for new ones.

As shown in the model presented in Figure 3, several promising initiatives can be proposed that would make it possible to respond to the needs of SMEs and of other stakeholders in the region's development in matters of e-business awareness, training, and networking. The initiative proposed here is the development of a portal for the collective appropriation of electronic business in the Mauricie region. Figure 4 is a display of the portal prototype's home page.

This proposed portal prototype responds to the needs expressed by the region's entrepreneurs and development stakeholders, and fits on the region's characteristics in terms of infrastructure and networking. The objective of the portal is to propose a helpful tool permitting both SMEs and local or regional development agencies to find answers to the problems of training, networking, and human resources in IT and e-business. Moreover, the solution proposed is realizable within a reasonable time-frame in that it does not target all SMEs but specific strategically important sectors or industries that have been identified as actual or potential strengths for the region.

#### **Figure 4**

While such an initiative may be promoted from the top, it must be requested, accepted and assimilated and requested by the grassroots, i.e., the SMEs. As well, this solution should allow a maximum utilization of networks and IT as facilitating tools. In addition, a wise selection of credible participants should be made to assume leadership of the project and see to the

promotion, development, implementation, and evaluation of the proposed initiative. Finally, success factors of this initiative include the engagement and participation of various stakeholders as well as the financial support of the milieu and governmental authorities.

Can the creation of this portal introduce the idea of a met@-network, that is, a regional virtual space of learning management, exchanges, and co-construction of knowledge? The networks set up by SMEs and the regional stakeholders can be seen as extremely rich reservoirs of explicit and tacit learning that remain badly exploited at present (Julien et al., 2003). With the potential offered by IT and e-business, would it be possible to increase the region's intellectual capital and make it accessible in real time to all the members of the met@-network? And how could we persuade members of this met@-network to join in virtual collective processes of co-construction of knowledge in view of the accelerating pressures on SMEs in regard to globalization? These are questions that call for further research on the potential of IT and e-business to enable the strategic development of SMEs and their region, that is, their market development (internationalisation), product development (innovation), and network development. (social and intellectual capital).

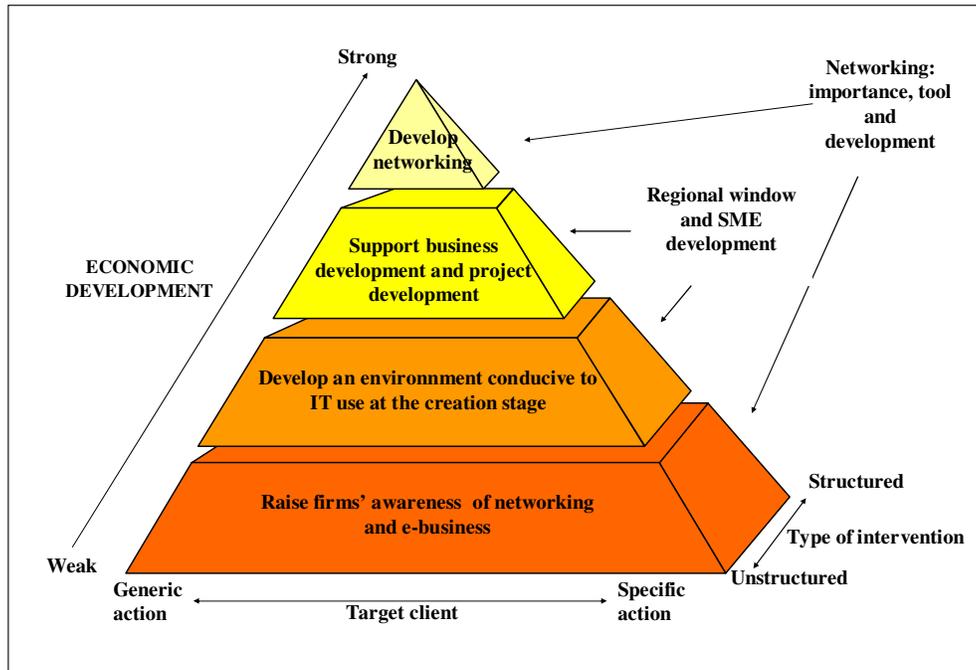

Figure 4: Home page of portal prototype

The screenshot shows the home page of a portal prototype. At the top, there is a navigation menu with links: Accueil, Mission et Partenaires, Informations, Glossaire, Contactez nous, and Recherche. Below the menu is a search bar. The main heading reads "La communauté des Affaires Électroniques en Mauricie".

The central part of the page features a map of the Mauricie region. Various actors and SMEs are marked on the map with icons and labels: C3e Technologies, CLD Les Chenaux, GDG Environnement Ltée, Municipalité de Trois-Rivières, Meubles EG, Infotek Centre de l'ordinateur, Carrefour virtuel de la mauricie, Claude Noël Consultants, CRDM - Conseil régional de développement de la Mauricie, Municipalité de Shawinigan, CIVAM, Mégatech Électro Inc., Technopole Vallée-du-Saint-Maurice, Autobus 2001, CLD de Maskinongé, and Sogi Informatique. A legend below the map identifies the icons for "Acteurs" and "PME".

On the left side, there are three main sections:
 

- PME**: Includes "Développement de la PME" (Introduction aux affaires électroniques, Formations, Meilleures Pratiques, Ressources pour passer à l'action, Veille sur les affaires électroniques, Veille stratégique) and "Réseautage" (Tableau de bord de la Mauricie, Contacts).
- Vitrine Régionale**: Includes "Portrait de la Mauricie", "Cas succès de PME en affaires électroniques", and "Municipalités".

On the right side, there are two panels:
 

- Filtre**: Contains checkboxes for "Acteurs" and "PME", both of which are checked.
- Actions**: Contains six icons representing different actions: a document, a telephone, a computer monitor, a printer, a mail envelope, and a person with a speech bubble.

At the bottom left, there is a detailed information box for CIVAM:
 

**CIVAM**  
**Adresse:** CIVAM, 121, rang de la Petite Rivière, local 25, Louiseville (Québec), Canada J5V 2H3  
**Téléphone:** (819) 228-0466  
**Télexcopieur:** (819) 228-2399

## **Summary**

We have reviewed an activity-based program with the objective to teach students managerial skills by empowering them to teach entrepreneurship within their communities. The Students in Free Enterprise (SIFE) program brings together executives (who sponsor the program globally), students (from any tertiary school), faculty (to coordinate the student effort) and communities (where the students teach others to perform real projects). Students in the US, Singapore, China and New Zealand report significant learnings from the program, with distinct differences in the benefits reported in the different cultures. Communities report lasting benefits long past the student involvement, and students indicate quality interactions with corporate leaders

## **Background**

Globalisation has resulted in the emergence of a new entrepreneurial economy, bringing two fundamental globalization factors: Firstly, the availability of low cost but highly skilled competition in Central, Eastern Europe and Asia. Secondly, the technology revolution which has reduced the cost of shifting standardized high economic activities out of high cost location like Europe into low cost location elsewhere in the world (Audretsch, D & Thurik, R, 2001). This shift from a managed economy to an entrepreneurial economy has intensified the need and market for entrepreneurial education which produces graduates with practically relevant skill sets. Entrepreneurship education has been identified as a critical factor in preventing future high levels of long term unemployment, and there is evidence of a strong correlation between educational level achieved and high income over a lifetime (De Faoite, D., Henry, C., Johnston, K., Van der Sijde, P., 2003).

The skills and knowledge, as developed through training and education, are one of the few areas where a country can engineer a competitive advantage (Kennedy, 1993), and our interest in this cross-border research is to identify how effectively different nations use a specific entrepreneurship education approach. We hope to be able to identify better and not-so-good performers and speculate as to the reasons why in some Asian countries certain entrepreneurship education techniques are more effective than in others. As suggested by Ulrich (1997), the importance of entrepreneurial education is derived from the importance of the entrepreneur throughout the economic system, and we believe that there remain significant differences in the entrepreneurship

education sector throughout the world, even after the onset of globalization efforts which 'shrink' the world of business. As entrepreneurship educators, our challenge is to identify the most effective means of teaching entrepreneurship principles and techniques, and we hope to describe the relative effectiveness of one technique throughout several countries within the Asia region, and in contrast to other countries throughout the world.

Many global businesses, as well as large national firms in the United States and overseas, utilize access to participants in the Students in Free Enterprise (SIFE) program as an efficient and effective method to identify senior level students with a demonstrated track record of managerial experience, and a background of practically relevant business education (Mueller, J., Wyatt, R., 2005)

SIFE uses the approach to stimulate students to teach entrepreneurship and free market principles within their own communities. This method presumes that the preparation for the teaching, the education itself and the subsequent effectiveness evaluation, in combination, greatly increase the learning effect for the students, and develop project management skills. At the same time, communities benefit through the reality-based application of projects intended to teach the effect of entrepreneurship, teach specific skills and review the outcomes. The SIFE requirements place a heavy emphasis on ethical and sustainable project design and execution, elevating the level of business education to include contemporary themes. Anecdotal evidence from areas where these SIFE teachings have been offered for several years, i.e. teaching poor villagers in Ghana how to use palm fronds to make commercially viable soaps (SIFE, 2004), indicates that these projects have the potential to operate for many years, generating their own profits.

Corporate executives, the sole financial supporters of the more than 1,800 SIFE student teams worldwide, report with a high degree of enthusiasm from their experience as judges at the student competitions, or when discussing their interest to recruit these student-turned-managers. In Singapore, the Managing Director of Korn/Ferry International writes: "We support SIFE because SIFE gives emerging managers the chance to tackle practical management challenges – and to demonstrate their commitment to their communities at the same time" (Chai, 2004). In the United States, KPMG's Vice Chairman Industries writes: "SIFE has a leveraging impact. We are reaching out to the next generation, getting them excited about free enterprise. This is a meaningful, long-term fundamental cause" (Moser, 2005). Personal observations indicate that corporate executives see value in the

interaction among each other, creating a sub-selection of firms with a strong interest in a public commitment to sustainable and ethical enterprise, actively and immediately approach students for recruitment and use their involvement in this program to support their competitive positioning. There appears to be a strong personal commitment of these CEOs and Board Chairmen, to the cause of enabling students to perform managerial work while still at university.

### **Framing of the Issue**

We have surveyed students in China, New Zealand, Singapore and the United States as to their performance and self-perceived outcomes of these intense projects, in which they invested several hundred hours of personal time over the academic year. By reviewing the same project in different countries we hope to eliminate program-specific variables and focus on the net effect of this entrepreneurship education.

### **Methodology**

Students are eligible to participate in SIFE when they are enrolled in a tertiary school, and we have distributed a net-based survey (Appendix A) to students in Australia, Singapore, China and the United States, through their faculty advisors at their universities. A total of 124 replies were collected, with responses from 24 Chinese students, 16 New Zealand students, 72 United States and 12 Singaporean students.

## Study Results

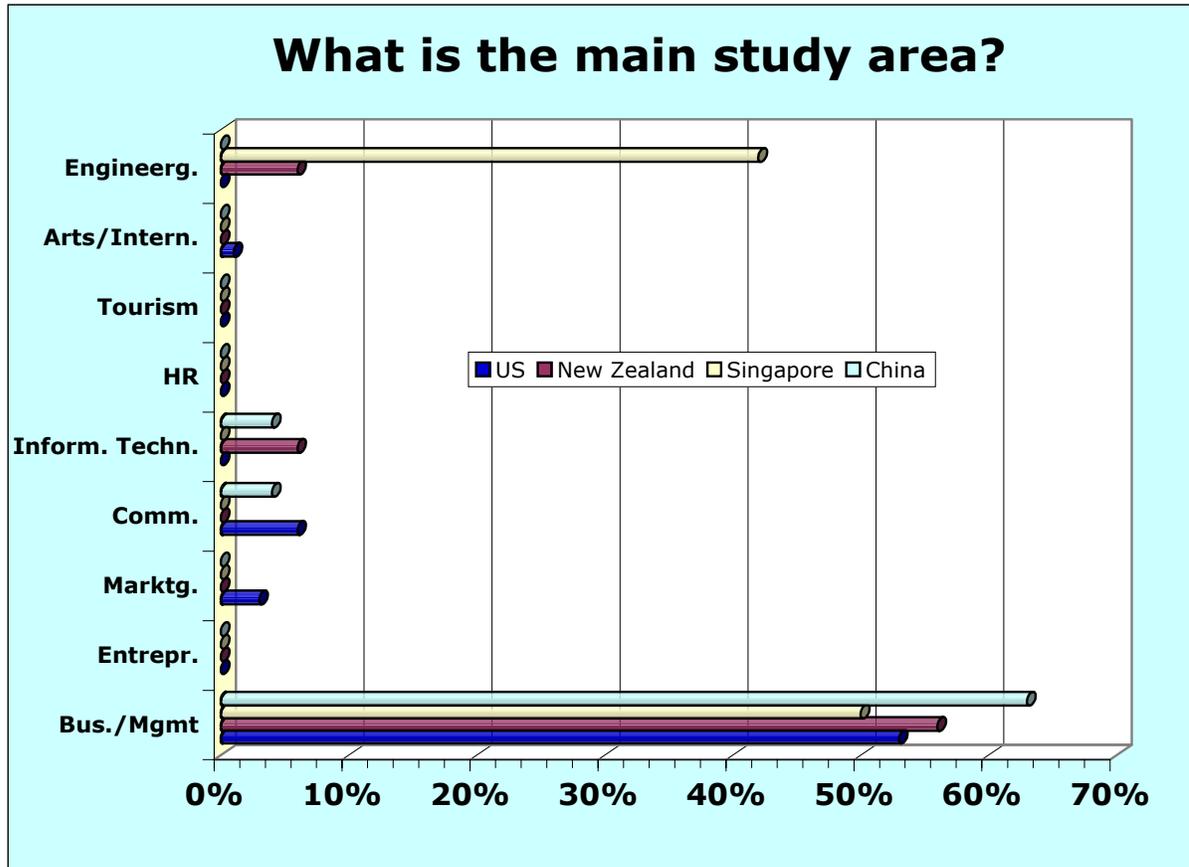

Table 1

With the exception of Singapore, where a significant number of students were from an engineering program, the majority of students were from business and management schools, and related areas, such as Communications and Marketing. One of the objectives of SIFE is to approach students in different disciplines, to broaden the community experience they bring to the program, and it appears that the uptake by non-business students is still slow.

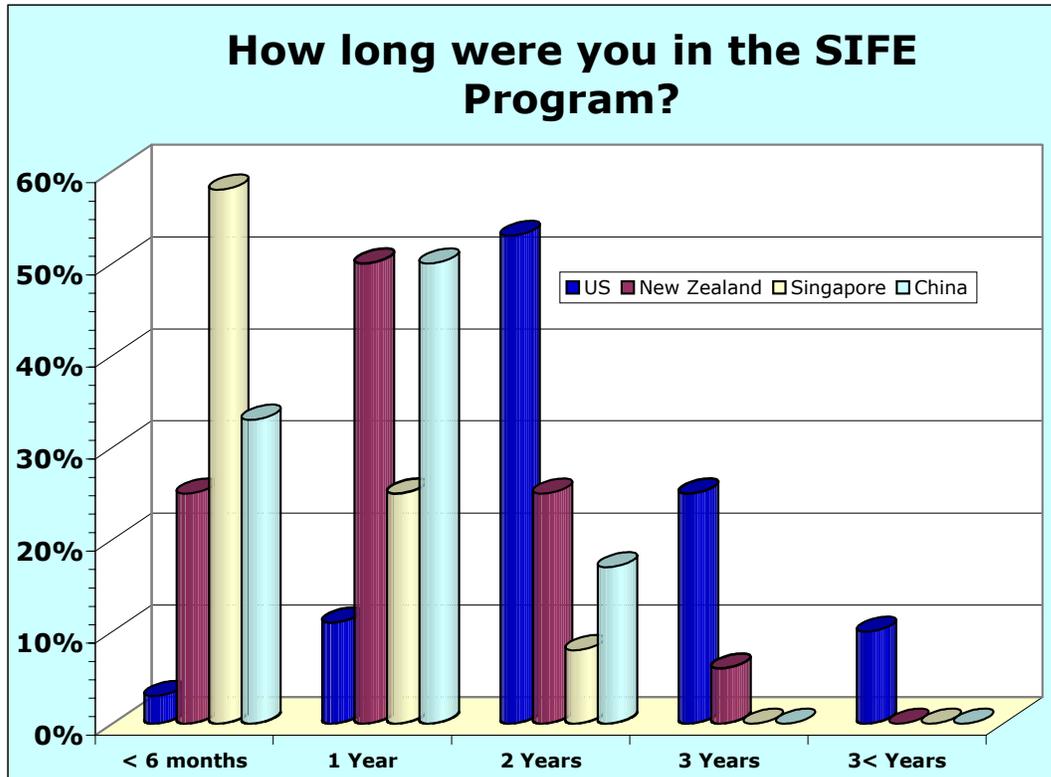

Table 2

While the United States students had been involved with SIFE for several years, not surprising given the program's origin in the US in the 1970s, students in the other countries have had only limited experience, some reporting less than 6 months' exposure (nearly 60% of the Singaporean students). We are therefore even more curious as to the effect the program might have on these students based on their short-term participation. A longer participation period likely would amplify any benefits and allow for internal governance procedure to be established within the SIFE teams, allowing for succession planning and a wider inclusion of students with different backgrounds.

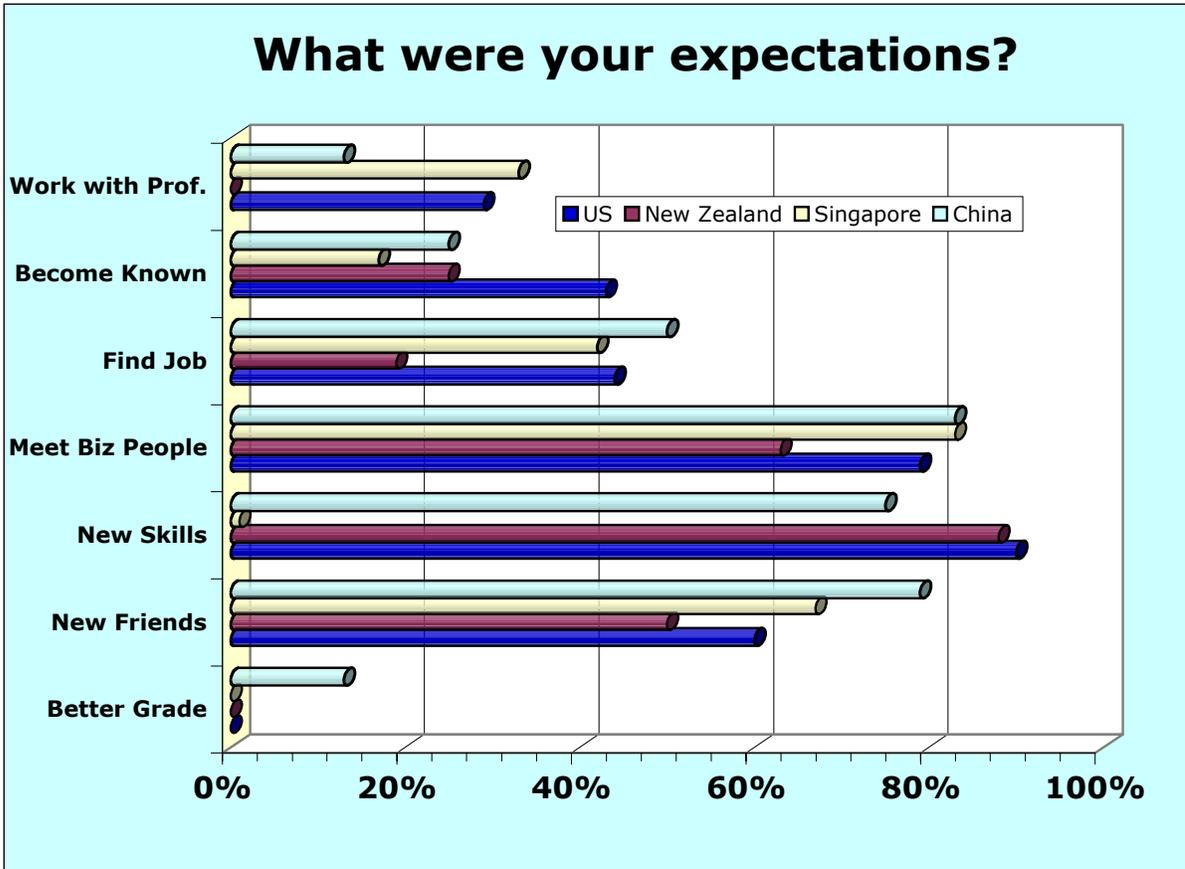

Table 3

Students expected most frequently to learn new skills and to meet business leaders, a universal reply for all four countries. “Making Friends” ranked highly in the Singapore, US and China programs, and to a lesser extent in New Zealand. The expectation of a better academic grade was not a factor in any country, indicating that the students are prepared to engage in significant extra-curricular work in return for networking opportunities and career-positioning. The authors’ first-hand experience, during their part-time work for SIFE, indicates that several SIFE students are hired by sponsoring corporate leaders directly ‘off the stage’. Several other SIFE students are hired following the exposure they get during the national competitions, where executives and their HR managers can interact with students on a more effective basis than during a job interview. These students therefore have a justified expectation that their SIFE participation assists them with their job search, either directly related to a SIFE event, or indirectly through the membership in the program.

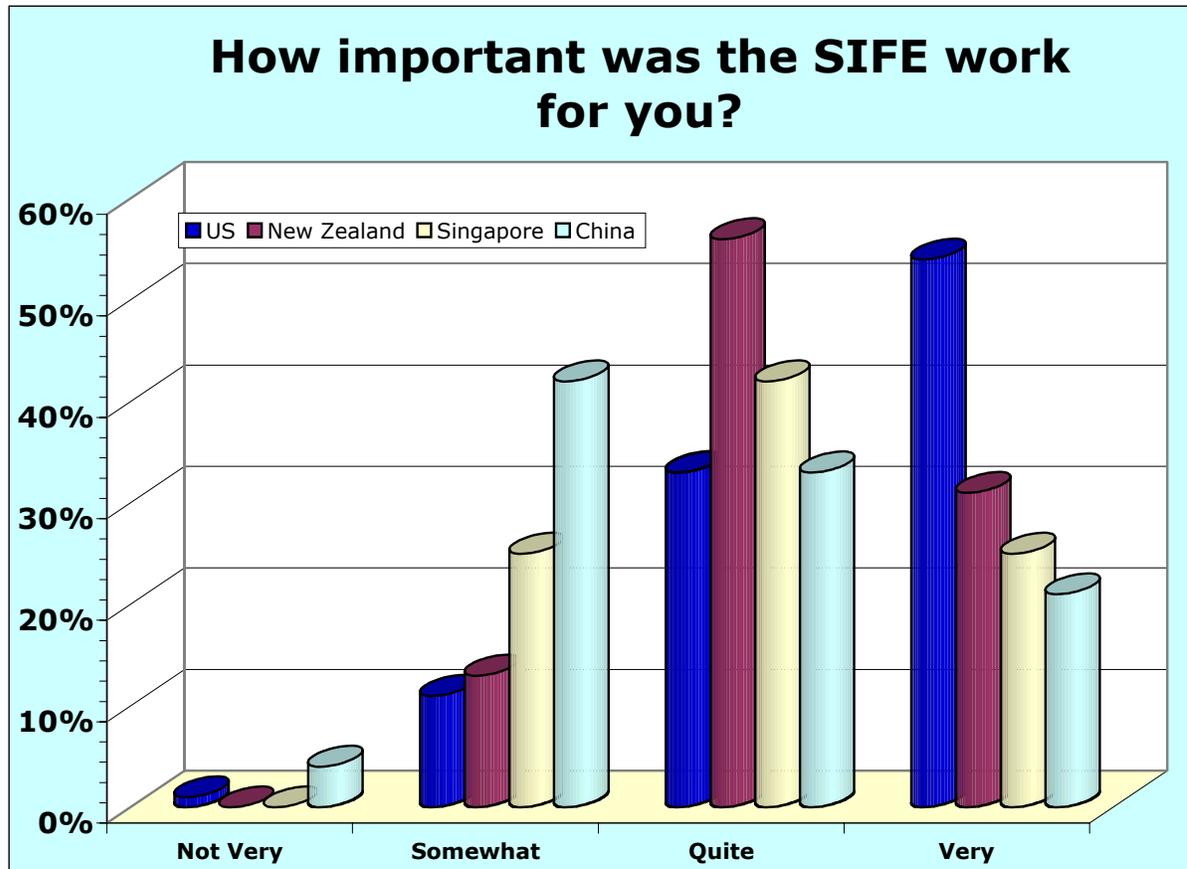

Table 4

The vast majority of students in all countries, led by students in the US and New Zealand (with more than 90% of all replies), indicated the SIFE participation was either “quite” or “very” important to them. This bodes well for their interest in entrepreneurship and community involvement, and confirms that these students have the willingness and resources to engage in practical work outside of the classrooms. With the several hundred hours each SIFE student performs during project work per year, this is an extraordinary commitment by the students.

## What was the effect of your SIFE work on others?

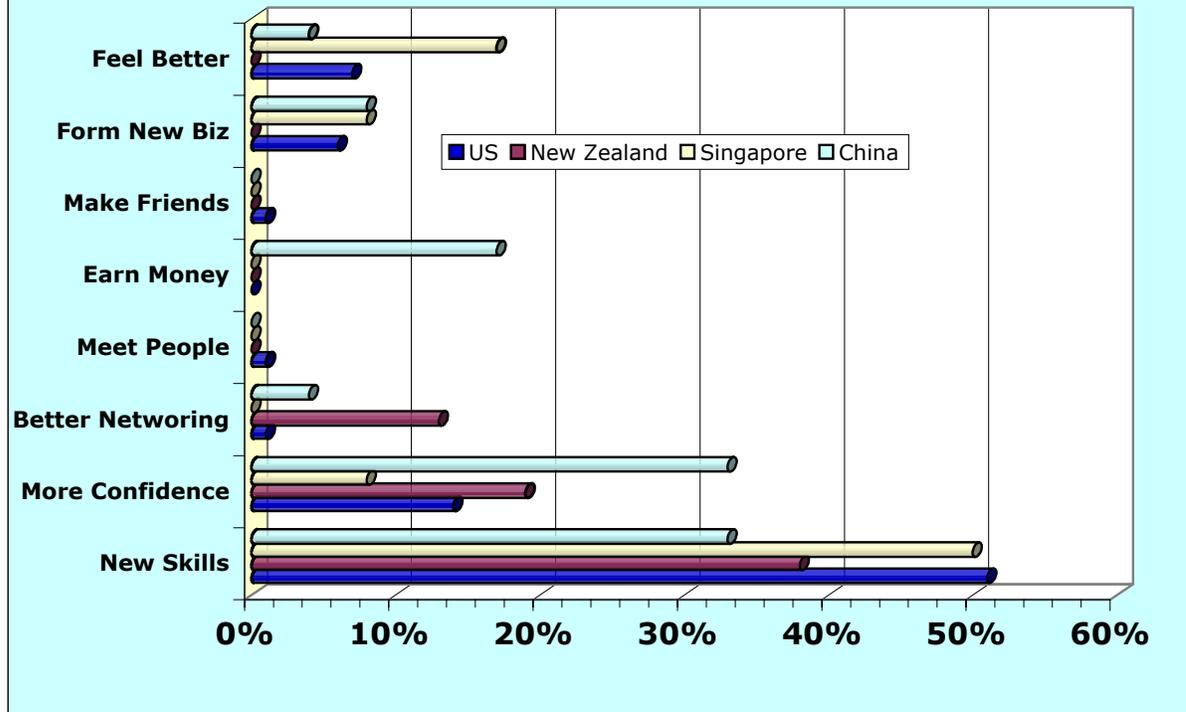

Table 5

With the exception of China, where some 15% of students reported monetary gains for their community clients, the effect on the communities was more intrinsic. Students report to a large extent that they helped build commercial skills during their work, helped increase the confidence level of community members and, in New Zealand, increased the networking abilities of communities. The teaching abilities of the students, building economically relevant skills among third parties, are important for the students' career progression as it demonstrates managerial abilities in project design, implementation, salesmanship and performance evaluation. The China student efforts resulted in a significant income increase for farmers in rural China, where the students recruited the help of multi-national Cargill, to develop a crop rotation scheme which tripled local farming incomes (to appr. \$300/year). To achieve this goal, the Shanghai-based students travelled a total of more than 15,000 railroad miles to visit the farmers several times, to conduct local workshops, educate on the benefits of multiple crop yields, and to monitor the project's progress. The program connected urban students to rural remote communities, demonstrated

the students' effectiveness in promoting a new scheme to a sceptical farming community, and resulted in clear learning results for all parties.

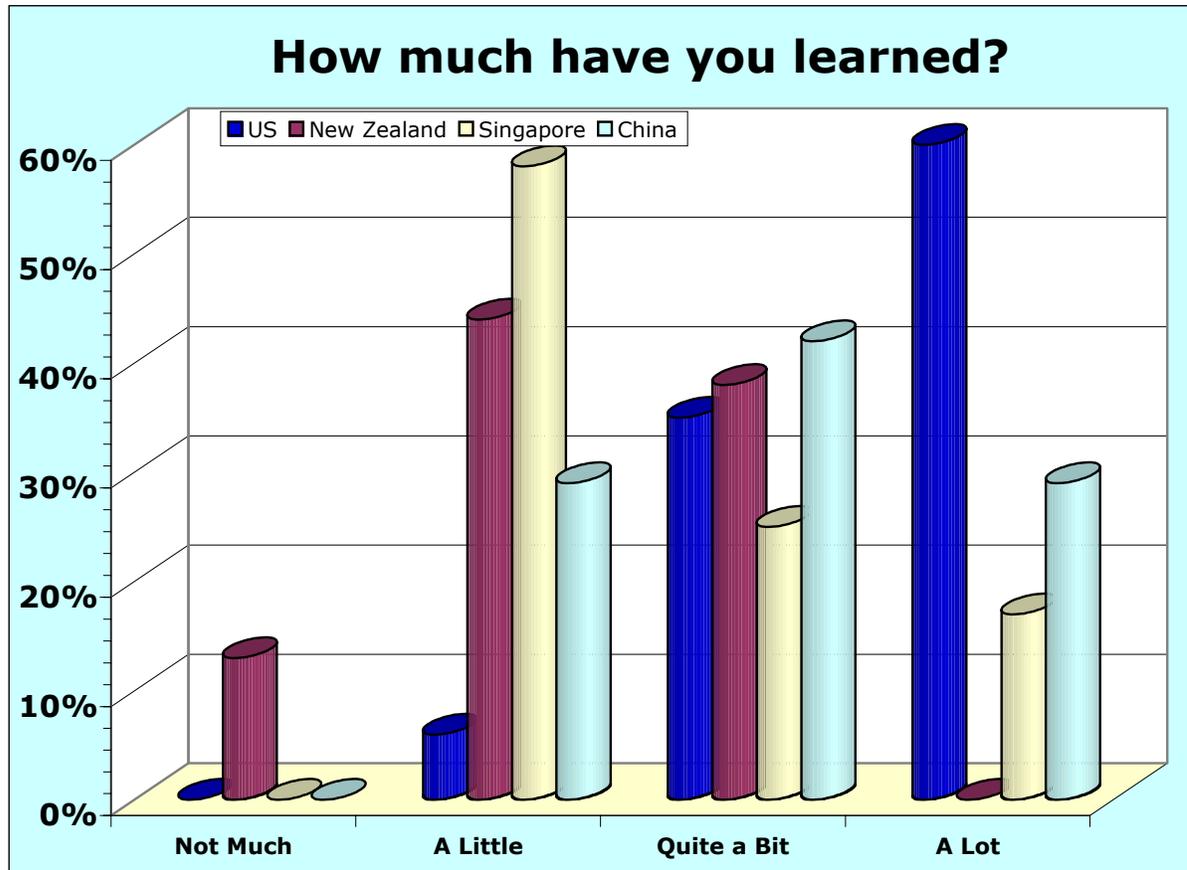

Table 6

As educators we always wonder whether the students actually appreciate the learning we offer at universities. In this case, the vast majority of students admits to "quite a bit" or "a lot" of learning, with only Singaporean and New Zealand students (the newest participants in the program) reporting approximately 50% of "a little" learning. In the United States, where the students were involved in the program for the longest period of time, the learning is indicated at the highest level, answering our earlier question whether longevity in the program deepens the experience. We conclude that it would be advantageous for students to be enrolled early during their academic career so that they have a longer time period during which to actively participate in SIFE, to participate in the community teachings and to interact with corporate leaders and sponsors.

## **Appendix A**

Please tell us about yourself:

1. How old were you when you joined SIFE?

AGE in years

2. At which university did you join SIFE?

UNIVERSITY Name Here

3. Which campus of the university did you attend?

CAMPUS Name Here

4. Which discipline did you study at university?

Business/Management

Entrepreneurship

Marketing

Communications

Information Technology

Human Resources

Tourism/Hospitality

Arts/International Studies

Engineering

Other DISCIPLINE here:

5. Did you study:

Full-time?

Part-Time?

6. For how long were you a member of SIFE?

1/2 year or less

1 year

2 years

3 years

More than 3 years

7. What year of study were you in, when you joined SIFE?

Undergraduate 1st year

Undergraduate 2nd year

Undergraduate 3rd year

Undergraduate 4th year

Undergraduate 5th year

Masters/PhD Program

Post-Graduate School

8. Did your SIFE team win any awards? Check all that apply

Special Competition

Rookie Award

Regional Winner

Opening Round Runner-Up

Opening Round Winner

Final Round Runner-Up

National Champion

Tell us about your reasons for joining SIFE:

9. How/from whom did you first hear of SIFE?

Lecturer at institution

Institute-wide announcement (bulletin board, internet, etc.)

Fellow student

University Club/Societies Office

SIFE web site (local country or worldwide)

Newspaper, etc.

Business/Corporate contact

OTHER:

10. Why did you join SIFE? (check all that apply)

SIFE was part of a course I took

A friend was in SIFE

I was curious

I wanted contact to potential employers

I wanted to travel to a SIFE competition

I got academic credit for SIFE

It sounded like fun

OTHER reasons:

11. What did you expect from your participation in SIFE? (check all that apply)

A better grade for my course

Making new friends

Learning new skills

Meeting business people

Finding a job

Being known within the university

Working more closely with my lecturer

OTHER expectation:

12. What role did you have in your SIFE team? (check all that apply)

No special role

Chief Executive/Team Leader

Technical Support

Presenter

Project Management

Recruitment

Public Relations

OTHER role:

Tell us about your commitment to SIFE:

13. How many hours did you spend on SIFE each WEEK on average?

Less than 5 hours 6 - 10 hours 11- 20 hours 20 and more hours

14. What importance did your SIFE work have for you?

Not very important

Somewhat important

Quite Important

Very Important

15. Did you have to give up other activities in order to perform your SIFE work?

Yes, gave up some leisure activities.

Yes, gave up some academic activities.

Yes, gave up some of both academic and leisure

No, gave up nothing

Tell us about the outcome of your SIFE work for others:

16. What kind of projects did you do? (check ALL that apply)?

Educating children about business  
Improving the environment  
Teaching adults about business  
Helping existing businesses develop

Helping start new business(es)

Working with Government organizations

Projects outside the country

Projects together with other SIFE teams

OTHER Projects:

17. How many projects did your team do in an average year?

1 2 3 4 5 6 7 8 9 10 11 and more

18. How many people do you estimate your project(s) affected, touched, helped, etc.?

NUMBER of people:

19. How did your work affect the people you taught/dealt with?

They learned new skills

They felt more confident about business

They developed new networks

They met new people

They earned more money

They made new friends

They started a new business

They felt better about themselves

OTHER results:

Tell us about the outcome of your SIFE work for yourself:

20. How much have you learned?

Not much A little Quite a bit A lot

22. Have you developed new skills?

Not much A little Quite a bit A lot

23. Has SIFE participation helped your career?

Not much A little Quite a bit A lot

24. Has SIFE participation helped you with your personal relationships, or your family?

Not much A little Quite a bit A lot

25. To what extent has SIFE participation added to the teaching at your university?

Not much A little Quite a bit A lot

26. How important is it that SIFE participation carry academic credit at your university?

Not much

A little

Quite a bit

A lot

Please share some reflective thoughts with us:

27. How well were your expectations met?

My expectations were NOT met

SOMEWHAT met

Met to a LARGE EXTENT

My expectations were EXCEEDED

28. If your expectations were NOT met, why not?

29. If you could made 3 changes to the SIFE program, what would they be?

30. Which 3 statements would you use to recruit a new student to SIFE?

***OWNERSHIP STRUCTURE AND BUSINESS EVALUATION***  
***PRACTICES IN FAMILY SMEs: EVIDENCE FROM***  
***EMPIRICAL RESEARCH IN ITALY.***

*Donata Mussolino – Amedeo Pugliese – Riccardo Viganò*

*University of Naples “Federico II”<sup>1</sup>*

**Abstract**

This paper presents early results from a pilot project which aims to investigate the relationship between proprietary structure of small and medium- sized Italian family firms and their owners’ orientation towards a “business evaluation process”.

Evidence from many studies point out the importance of family business in a worldwide economic environment: in Italy 93% of the businesses are represented by family firms; 98% of them have less than 50 employees (Italian Association of Family Firms, 2004) so we judged family SMEs as a relevant field of investigation.

In this study we assume a broad definition of family business as “a firm whose control (50% of shares or voting rights) is closely held by the members of the same family” (Corbetta, 1995).

“Business evaluation process” is intended here both as “continuous evaluation process” (which is the expression of a well developed managerial attitude) or as an “immediate

valuation” (i.e. in the case of new shareholder’s entrance, share exchange among siblings, etc).

We set two hypotheses to be tested in this paper: the first is “quantitative” and aims to verify whether the number of owners (independent variable) in a family firm is positively correlated to the business evaluation process.

If a family firm is led by only one subject, it is more likely that personal values, culture and feelings may affect his choices more than “purely economic opportunities”; so there is less concern about monitoring economic performance or about the economic value of the firm. As the shareholders’ number increases, economic aspects in managing the firm grow in importance over the personal values and "value orientation" acquires a central role.

The second hypothesis investigates if and to what extent the presence of “non- family members” among the owners affects their orientation to the business evaluation process.

The “Cramer’s V” test has been used to test the hypotheses; both were not confirmed from these early results; next steps will lead to make an inferential analysis on a representative sample of the population.

### **Introduction and theoretical assumptions.**

This research investigates the relationship between ownership structure of family small and medium enterprises (SMEs) and their owners’ attitude towards the firm’s evaluation process. Below we present some results from a pilot project of an ongoing empirical analysis in the Italian context.

Evidence from many studies point out the importance of family business in a worldwide economic environment: according to a joint survey led by the Bank of Italy and the Italian Association of Family Firms (AIdAF), family firms represent the 93% of total firms and 98%

of the workforce in manufacturing companies fewer than 50 employees in Italy (Bank of Italy, 2004). Relevance of family firms is combined with importance of small and medium-size firms. Most small and medium firms are family owned and account for a significant portion of the Italian economy: small and medium-size firms employ 93% of the workforce and represent over 99% of total companies, according to the national Institute of Statistics (ISTAT, 1991).

The ownership structure of family firms has been widely investigated in two different fields: *Corporate Governance* and *Family Business*. Distinctions between alternative forms of ownership (family business versus non family business) have been a viable assumption for many researchers; they consider it a “discrete determination” (Astrachan, Klein & Smyrnios, 2001) since their interest has been to define a “continuum spectrum” which goes from the “entrepreneurial business” to “professionalized firms” in order to exploit the differences between family and non family firms (Daily & Thompson, 1994).

Since the leading idea is that ownership typology conditions firm processes, outcomes and value, many researchers disagreed as to whether, and to what extent, there are differences between family and non family firms. On this point academic literature is not unanimous.

While Gudmundson, Hartman & Tower (1999) found no difference in strategic orientation and behaviour between family and non family firms (Daily & Thompson, 1994), Ward (1988) states that strategic planning processes in family business significantly differ from non family business, also assuming it remains necessary to manage the firm.

Ownership structure has also been tested to assess whether family firms perform better or not than non family firms (Gallo, Tapies & Cappuyns, 2000); accordingly, a few studies suggest that family ownership per se does not create or destroy value (Villalonga & Amit, 2004), alleviating simply the conflict of interests between owners and management (Berle & Means, 1932).

When the focus switches to family firms alone, researchers define the ownership configuration according to the different phases they (FB) pass through, each with challenges and characteristics (Ward, 2001). As the interaction of business and family life-cycle with owners' decisions changes, it determines the shareholders' composition. It varies through six different phases from entrepreneurial to collaboration and family syndacate.

We found little evidence as regards the relationship between ownership configuration and the "business evaluation process".

The F- Pec scale (Astrachan, Klein & Smyrniotis, 2001) defines the "ownership configuration" as one of the most influencing determinants for the "power level" of the family over the firm; it increasingly affects family involvement (Astrachan & Shanker, 1996) as the overlap of family, ownership and management groups grows within the firm (Davis & Tagiuri, 1999).

If on the one hand the level of family involvement is determined by the ownership configuration, on the other it strongly influences the system of values (or the values themselves), aims and objectives of the firm itself; since the firm is seen as an instrument to reach owners' objectives (Ferrero, 1987) these may vary across people and time, taking shape diversely from firm to firm. Emotional attachment to family firm ownership may detract from the firm's focus on economic goals; thus a typical family firm violates almost all the underlying assumptions of traditional governance theories (Mustakallio, Autio & Zhara, 2002).

At the same time the "shareholder value approach" (Fernandez, 2001) and "shareholder value maximization" (Copeland, Koller & Murrin, 1996) cannot be fully applied to the family business model; owners' expectations and objectives rely upon a personal system of values which could overwhelm the economic and financial perspective. Existing duality between economic and non-economic goals help us to define "value assessment" within the family

firm: private benefits and “amenity (potentials)” are a relevant part of the whole value configuration (Demsetz & Lehn, 1983).

Hence interest towards economic value assessment varies through the different scales of family involvement over the firm: the “family effect” seems to be inversely correlated to the “purely economic goals”; as a consequence, owners are less concerned with monitoring economic aspects while running the firm.

Literature about firm value and evaluation process focuses mostly on the several objectives of firm value assessment and its evaluation techniques; a common concern is that business evaluation is essential for the decision making process and management of all firms.

There are two main approaches when considering the firm’s value assessment: the first one is immediate, evaluation occurs either with an extraordinary transaction (such as merger, share exchange, acquisition, shareholder’s exit and entrance, split, etc..) or during a succession phase; the second approach is systematic and it emerges as a recurrent performance evaluation, intentional strategy and investment project (Viganò R., 2001).

### **Hypotheses formulation**

We set two hypotheses to be tested in this paper as regards the influence of the ownership structure of family firms over the family- owners’ attitude towards economic appraisal.

Shareholders’ composition may modify the extent of the “family effect” over the firm; as family involvement grows, the more likely it is that private benefits and non- economic goals will gain importance over the pure economic goals: family- owners have little (or no) interest in monitoring the value of the firm when approaching strategic decisions.

If a family firm is led by only one subject (ownership configuration), it is more likely that personal values, culture and feelings may affect (family involvement) his choices more than

“purely economic opportunities” (value assessment); thus there is less concern about monitoring economic performance or the total value of the firm. As the number of subjects increases, even if they are still family members, social interaction decreases (Mustakallio, Autio & Zhara; 2002) and economic aspects in managing the firm gain more importance than personal values: monitoring the "value creation" gains a central role.

---

Insert figure 1 about here

---

*H<sub>p</sub> 1: in family firms there is a positive correlation between the number of shareholders and their attitude towards a firm evaluation process.*

The second hypothesis investigates a more “qualitative” aspect about the structure of the family firm; it examines whether the presence of “non- family members” among the owners may affect their leaning towards the business evaluation process.

---

Insert figure 2 about here

---

*H<sub>p</sub> 2: in family firms, the presence of non- family members among the shareholders increases the owners’ attitude towards a firm evaluation process.*

We expected both hypotheses to be confirmed; hypothesis 1 will be verified if “Cramer’s V” test is significantly far from zero (approximately around 0.6), while hypothesis 2 will be confirmed in case the test- value is higher than the other.

## **Methods**

Below we present results from a pilot project carried out between July and December 2004 on a group of Small and Medium Family Businesses.

As no official database exists for Family Enterprises in Italy, we lack information on the real size and the main features of such a group of firms. The survey has been led through a web-questionnaire, emailed to 1.105 companies chosen from the databases of the “Entrepreneurial Association” of Naples and Milan; a cover letter from the Association they belong to was gone ahead the questionnaires.

A total of 120 completed questionnaires were returned, with a response rate of 10,9 %.

The final sample is of 88 firms as we erased non- family firms, large corporations and incomplete or incorrect answers.

### *Definition of family firm.*

In this study we assume a broad definition of family business as “a firm whose control (50%+1 of shares or voting rights) is closely held by the members of the same family”.

Whenever a firm is owned by only one subject, we considered it as a family firm only when at least another family member is involved in the enterprise activities. In our final sample, we identified family firms crossing the questions about the percentage of capital (rights to vote) owned by one family, with the presence of family members among the employees -managers.

### *Definition of SMEs.*

We consider as “small or medium firm” an enterprise whose turnover is less than 50 million of euros per year, and if it employs less than 100 people in one year. Two questions are set up to meet those parameters: turnover ranges across nine different levels, from less than 2,7

million up to more than 1.000 million of euros per year; employees' average number per year varies across six different levels, from "less than 20" to "more than 1.000".

*Questionnaire overview.*

The questionnaire is structured and semi- closed; it was addressed to owners, managers or members of the board. They were asked to fill in all the three parts according to the instructions.

- Section A (5 items) is addressed to the person him/herself: it defines the respondent's profile in terms of position, tenure, ownership, relation to founder (if existing), sex and age.
- Section B (12 items) deals with the firm's profile in terms of age, generation, (involvement) in a succession process, geographical location, core business, legal organization, sales performance, number of employees, industry and business growth rate, ownership structure in terms of shareholders' concentration and number of non family members among the owners.
- Section C (8 items) focuses on the business evaluation process: first they were asked whether the firm has ever been evaluated. Should the answer be positive, they also specify 1) on which occasions they took this step (multiple choices depict all the different objectives in a firm evaluation process: selling off the activity, shares exchange among siblings, mergers & acquisition, financing, succession or performance assessment); 2) frequency of the evaluation process (if it is a one- off or recurrent); 3) who leads the value assessment (consultants, managers, owners); 4) the evaluation techniques and if "family discount rates" were applied. Should the answer be negative, respondents are asked if they have any interest in knowing the firm value, and if they perceive any advantages or disadvantages in ignoring it. The last question concerns the presence of a "Family Pact" or if, in some ways, a succession process has been planned.

*Measuring the two investigated variables.*

“Ownership structure” is intended here simply as the shareholders’ composition; in order to define this variable through all firms, we set up three specific items about the following issues: i) how many owners the firm has; ii) the percentage of shares owned by a single family; iii) the presence of non family members among the owners.

When assessing the variable “firm evaluation process”, we investigated three specific items:

1. the first uses a “binary variable” on responses to the question concerning whether the firm has ever been evaluated or not;
2. the second item investigates the objectives of the firm appraisal: it might occur “external and occasional circumstances” (selling off entirely or partially the firm, share exchange, etc.), or during a “firm’s performance measurement”;
3. the third aspect raises the question about the frequency of the evaluation process, if it is an “immediate evaluation” or a continuous (periodic) one.

The two variables have been crossed in a double entry matrix according to a “bivariate analysis model”; hence we obtained the total frequencies for the investigated relationship and the “Cramer’s V test” was performed.

## **Results.**

To test the effects of ownership structure on the firm evaluation process, we analysed a final sample of 88 firms.

Table 1 represents the ownership structure of all the firms in the sample; it summarizes their frequency distribution into the different classes according to their shareholders’ number.

Since we did not find any firm with more than 9 owners, we identified only five classes. In

the column “conditioned frequencies” we classify only the firms with at least one non family member among the owners.

---

Insert table 1 about here

---

Table 2 shows the frequency distribution of the evaluation process. In the third column (evaluation process) we sub- divide the firms according to their answers about the frequency of the evaluation process whether it is a continuous approach or an immediate one. Events are dichotomous.

---

Insert table 2 about here

---

The table above, shows that 48.8% of the firms in the sample have been involved in a “business evaluation process”; 31% of them do it recurrently, while the remaining 69% took into step only occasionally.

We did not analyse specifically the reasons which led to the evaluation process, but it seemed quite interesting to cross them with their frequency (matr. 1).

---

Insert matrix 1 about here

---

As we chose a “pilot project”, we had support only from the descriptive statistics methods and no inference was attempted. Our sample is not representative of the whole population, consequently we can describe our results through a bi- variate analysis and a double- entry contingency matrix.

The “ $\chi$  square test” in a preliminary stage and the “Cramer’s V” were used to test both the hypotheses (table 3).

---

Insert table 3 about here.

---

Cramer's V index is used to measure the strength association for the contingency table. Since its value ranges between 0 (no connexion) and 1 (maximum connexion), our result (Cramer’s V = 0,08) suggests that the two variables are totally unrelated.

The third column shows how the percentage of frequencies for each class does not change significantly as the shareholders’ number increases, leaving frequencies around the general average of 48,8%.

*Hypothesis 1 is not verified.*

Such counter- intuitive results led us to go ahead with an in- depth analysis between the two variables.

Since there are relevant differences among a continuous evaluation practice of the firm and an immediate one, we tried to split them up to check whether or not ownership structure may have an impact on an on- going value orientation (table 4).

---

Insert table 4 about here

---

Neither does table above support our initial hypothesis. The possibility that firms are oriented towards a “continuous evaluation approach” does not depend on the shareholders’ number.

“Cramer’s V test” presents a result of 0.125, which is slightly larger than the overall value (0,08 ) but is not enough to suggest any connexion. The same results occur in case we analyse the occasional evaluation process since it is complementary to the other event.

---

Insert table 5 about here

---

To test hypothesis n° 2 we used the “ $\chi$  square test” in a preliminary stage and the “Cramer’s V”; we aimed to verify if the firm’s evaluation process would be affected by the presence of non- family members among the shareholders. Results fail to adequately confirm our hypothesis since the “Cramer’s V” test scores 0.38, which is larger than the overall value (0.08) but it is still too close to zero. Moreover the percentage of firms involved in a business evaluation process does not vary with the presence of non- family members among the owners.

*Hypothesis 2 is not (entirely) verified.*

### **Conclusion and research implications.**

These results indicate there is no relationship between the ownership structure and the evaluation practices of small and medium family firms. Hypotheses have been tested through statistical descriptive procedures (Cramer’s V), and we found no connexion between the two variables: neither the number of owners nor the presence of non- family members among the shareholders seems to be affecting economic value orientation in a family business.

When approaching a plausible explanation for unexpected results, we identified two possible reasons. Since we investigated the ownership structure of firms whose control is closely held by one family, we can assume that increasing the number of owners or the presence of non-family members does not reduce the “family effect”, which still strongly influences both the business strategic orientation and value assessment.

The second reason is linked to the legal organization of Italian firms. Choices about the legal organization mainly depend on the tax benefits and the limited liabilities provided to the firms organized under the “corporation- type”. “Limited liability companies” necessarily comply with more than one shareholder, but many of them might be fictitious only to reap in those benefits: in this sense ownership structure does not truly reflect the real “proprietary configuration” and the decision- making process is held in the “real owner’s hands”. As the managerial attitude is not affected by ownership structure, firm value orientation does not substantially change as the shareholders’ composition modifies.

#### *Implications for Theory*

Growing evidence highlights the importance of studying ownership structure of family firms; nevertheless, existing literature is not exhaustive in explaining how the shareholders’ composition can affect managerial attitude and economic value orientation in family firms. This study has sought to go some way to filling this gap and the pilot project represents the first step to be taken before an inferential analysis. Early results suggest that a deeper analysis about the relationship between firms’ features (legal organization, turnover, number of employees, etc) and their “economic value orientation” is required. A model based on a multivariate analysis will be used to measure the extent of their reciprocal influences. As we cannot extend those early results to the whole population, forthcoming steps will aim to find a representative sample of the population to allow inferential procedures.

#### *Implications for practice*

When approaching to family- owners' attitude towards "economic value orientation" we moved from the acknowledged idea that value orientation and performance measurement are necessary for the managers to better run the firm. Few studies attempted to explore the "value assessment" for family firms and how it differs from the non family business; strong agreement among researchers emerges when recognising that non- economic goals are as important as economic ones. Hence, both need to be monitored in order to reach an economic value driven approach either in strategic choices or to managing some crucial events in the family firm's life, such as the succession process.

# WHY DO SOME CLUSTERS STAGNATE?: EVIDENCE FROM TWO RESOURCE BASED CLUSTERS IN KERALA, INDIA

M.K.Sukumaran Nair  
University of Botswana  
Email: nairm@mopipi.ub.bw

**Abstract :** The available literature on small and medium enterprise clusters, while focusing on success stories have not so much addressed issues related to stagnation and failure. The present study of two resource based clusters in India seeks to address the question using empirical materials. Both the clusters have a history of half a century. They emerged in the context of plentiful supply of raw materials and cheap and skilled labour. They achieved some amount of growth during certain periods, but in respect of the key cluster characteristics such as innovation and sustained growth, they failed. A chief factor accounting for the stagnation is the depletion of the resource base. Both the clusters lack innovative behaviour and inter-firm collaboration. The enterprises in the cluster did not develop extensive forward and backward linkages. Sectoral specialization and inter firm division

of labour did not adequately develop. Clustering does not seem to be playing any role facilitating division of labour, diffusion of technical information and other kinds of cooperation between enterprises that would lead to higher over all efficiency. Absence of service establishments, input suppliers, receptive markets etc. prevented innovation in the cluster thereby compelling firms to adopt a sweatshop strategy. Though business associations do exist they have not been successful in raising the clusters' competitive advantage through providing support measures. The macroeconomic policy existing in the country has not been salubrious. There has not emerged adequate local level policy initiative or appropriate supportive institutions.

## **Introduction**

The extant literature on small and medium enterprise clusters largely focus on success stories in Europe (Piore & Sabel, 1984; Becattini, 1989; Humphrey, 1996; Sengenberger & Pyke, 1992) and to a limited extent in developing countries (Rabellotti, 1997; Schmitz, 1992; Knorringa, 1992; Cawthone, 1995; Holmstrom, 1993). There is very limited literature that addresses issues related to stagnation and failure particularly in developing country contexts (Pillai, 2000; Weijland, 1994; Klapwijk, 1997; Pedersen, 1994; Nadvi & Schmitz, 1994). These studies, though do point to the depressed background of the clusters, do not go into the debilitating factors. The present empirical study of two resource based clusters in Kerala, in south west India – a saw mill cluster in Perumbavoor and an agricultural implements cluster in Shornur – seeks to address the above question using empirical materials. This study is based on field data collected using detailed questionnaires and by participant observation from 59 small and medium units in Shornur and 50 in Perumbavoor selected at random.

## **Brief Profile of the Cluster**

The area extending from Shornur to Palghat in northern Kerala is the abode of the agricultural implements cluster. The two factors that led to the emergence of the cluster in this locality are cheap availability of good quality raw materials and skilled labour. The railway loco shed at Shornur used to have plenty of rail scrap that is excellent for the making of agricultural implements. The *karuvan* community of Shornur and the surrounding areas used to supply the necessary skilled workers for the industry. Another factor responsible for the origin of the industry in this particular region was the presence of Mr. C.K. Menon who was trained in metallurgy in Sheffield. The W.W. 11 gave a boost to the industry in the region. The import substitution industrialization strategy adopted by the government of India in the 60s gave a major boost to the industry. The industry had its best growth in the 60s and the 70s.

The cluster consists of all size classes of units although the majority belongs to the tiny sector. There are nearly 25 large units including a public sector company that employs more than 50 workers. There are about 200 small scale units each of which on an average employs 10 workers. The tiny units are estimated to be 300 located mostly in homesteads. The small start up units need only a small amount of capital, a small shed and a few traditional tools like a lathe. The tiny units employ two workers or less, mostly family labour. A wide variety of implements are produced in the cluster. They are mainly of three types: estate tools, garden tools and cutlery items. Though the industry had a good time till the late 80s, the 90s marked its decline. The reasons are wide ranging. The condition of cheap availability of railway scrap no longer exists. Moreover, the stagnant technology and lack of innovation led to the further slow down of the cluster. However, in response to sagging demand and mounting costs of production, some amount of diversification has taken place in the cluster. Most such units are at the homestead of the owners. What all they need is a grinding motor, drill, air blower, a few dies and a few hand forging and finishing tools.

The saw-mill cluster in Perumbavoor is located in the north eastern part of Ernakulam District. The easy availability of timber from the nearby forests made Perumbavoor the centre of saw-mill industry. This cluster has nearly 600 saw-mill units. But it is reported that 80 percent of the trading in the timber market takes place unlawfully without keeping proper vouchers. Since 1995 no new business enterprise has come to the cluster. Because of the crisis in the cluster, there has been a shift in the activity from saw milling to plywood manufacturing. The plywood manufacturing units also are facing a crisis situation now. MDF Prelaminated particle boards and medium density fibre particle boards which are superior substitutes to plywood are being imported from Malaysia and Indonesia at prices which are cheaper by 25 % than the local product. Moreover, there is tough competition from new varieties of plywood such as new wood, marine plywood etc. that come from other states in India. After the mid90s no new unit has come to operate in the area

### **Cluster Characteristics**

Thus both the clusters have a history of half a century. They achieved some amount of growth during certain periods, but in respect of the key cluster characteristics such as innovation and sustained growth, they failed. Thus the two clusters present a picture of

stagnation and pessimism. Such clusters are often called survival clusters (Knorringa, 2002). Both the clusters lack innovative behaviour and inter-firm collaboration. Sectoral specialization and inter firm divisional of labour did not adequately develop. Clustering does not seem to be playing any role facilitating division of labour, diffusion of technical information and other kinds of cooperation between enterprises that would lead to higher over all efficiency. Absence of small scale service establishments, input suppliers, receptive markets etc. prevented innovation in the cluster thereby compelling the units to adopt a sweatshop strategy.

### **Inter Firm Linkages**

The European experience prompts us to ask: why the clusters under review did not forge inter-firm relations, become innovative and develop efficiency and competitiveness? The clusters under study exhibit the characteristics of “latent” clusters, which have not developed the level of interaction and information flows necessary to truly benefit from colocation. The degree of division of labour among the firms is extremely limited in the two clusters. In the Saw mill cluster only 12 percent of the sample units seem to be engaged in any kind of subcontracting. In the agricultural implements cluster, the percentages of firms engaged in subcontracting is 47. 5. But this does not mean that inter-firm division of labour exists in this cluster. A chief reason for the existence of subcontracting relations in the cluster is savings on premises. As raw-materials in both the industry are bulky and space consuming, the firms subcontract the work mainly to save on space (Table 1). Similarly, there is no other form of interaction between the parent firms and the subcontractors either in terms of technical collaboration or financial or consultancy matters. (Table 2) The firms in general do not seem to be possessing adequate knowledge of other firms in the cluster. They seldom visit other production sites or exchange ideas about business (Table 3). Similarly they do not seem to have interaction with other firms and individuals. Lack of a common enough vision of their future and lack of the requisite level of trust among firms to find and exploit common interests are some of the bottlenecks experienced by them.

-----  
Table 1, 2 & 3 here  
-----

These groups of firms do not think of themselves as a cluster and as a result, do not think of exploring the potential benefits of close relationship with other local organizations. The enterprise structures, private and public services, labour markets and social networks have not adapted to each other and their specific environment. This probably is the main reason for the absence of collective efficiency in the cluster. These clusters are relatively disaggregated and less pronounced and consist of small firms operating under relatively poor and unregulated working conditions with less extensive backward and forward linkages. As the technology in the agricultural implements cluster is traditional, the workers have to spend a considerable amount of time near the fire at hazardous conditions. Besides, the use of charcoal for heating purposes pollutes the premises of the workshop. In the saw-mill cluster also no drudgery reducing technology has ever been employed. Similarly, the factory premises are polluted with wood dust. While

considering the forward linkages, it is seen that most of the sales of the units in the cluster are in near by localities. Only less than 25 percent of the out put is sold in distant markets in the country. Less than 4 percent of the output of the cluster is exported. The horizontal linkages are also not well developed. Though business associations do exist in these clusters, they have not been successful in raising the clusters' competitive strategy by providing support measures. These business associations have come up because there exists in Kerala the political culture of forming associations without much of a purpose. In both the clusters there are two associations. The interests of these associations are often conflicting. Moreover, the association is a decorative piece which does not perform any useful function. The activities of the association does not give an impression that the business men are aware of the fact that they are functioning in a cluster and that the environment of a cluster offers tremendous opportunity for growth by fostering inter firm relations ( Table 4). The relatively large units in the agricultural implements cluster have formed a separate business association, but they also do not share any critical information about technology or markets, particularly the foreign markets which they have access to. They fear that the leakage of business secrets will eventually deprive them of the opportunities to their competitors who are also members of their own association. In the saw mill cluster also one finds the relatively large units in collusion mainly to arrest the growing labour militancy. But apart from that they do not have any cooperation on the core business functions.

-----  
Table 4 here  
-----

It is further seen that it is the absence of opportunities in the formal sector that forced individuals to be self employed as small entrepreneurs in these clusters. As they do not have any idea of areas of potential advantages of making investment, they entered into areas where other firms were doing relatively well without making significant investments. This is evident from the fact that in both the clusters a majority of the entrepreneurs have no previous experience in business and more particularly, almost nobody has experience in the same field (Table 5).

Table 5 here  
-----

### **Innovation and Growth**

Innovation has been a casualty in both the clusters. In a developing country context innovation needs to be understood in a restricted sense: using different raw materials or economizing on the use of raw materials or energy, improving the design or introducing a new way to finance, distribute or stock products and changing the management of a small business (Van Dike and Sandee, 2002:4). Even in this limited sense the firms in the clusters have not shown any inclination towards innovation either in improving the quality or design of the products. The firms appear to be very conservative to changes. Unless there is strong market demand in their perception, they would not even adopt designs that are in fashion in the rest of the country. Moreover, the firms are very

cautious about spending money on design changing experiments. Similarly, the organizational structure of the units also has not changed even marginally at least during the preceding 5 years of the survey. The process of production has also remained more or less the same for decades (Table 6). On the whole, the entrepreneurs do not seem to be taking any initiative to introduce innovation for fear of high cost and insufficient demand in the market. They do not sufficiently realize that the market is in fact in the perception of the entrepreneur and that they can create market, if they want. They do not know that a cluster becomes successful only when they associate themselves with workers, traders, and other participants in the chain utilizing available and adaptable techniques and thus forming a collective production unit the scope of which goes beyond the individual enterprise. Almost all units surveyed do not want to share any information regarding purchase of raw materials, marketing of the products, financing or production with others in the cluster. Even when the entrepreneurs meet in the general body meetings of their business associations, they discuss entrepreneurial subjects in a general sense and not specific to the enterprises. The performance of the clusters does not paint a promising picture either. A majority of the units accounts for declining output and profit levels (Table 7)

### **Policy Initiatives**

However, once there is a critical mass of small and medium firms in a cluster, policy intervention may be able to play a role in fostering networking and growth. Such policy initiatives have been proved successful in the Italian and other European cases ( Brusco, 1990; Schmitz,1992) . The success of a cluster is contingent on the propitious macroeconomic climate in which it operates (Cawthone, 1995). The macroeconomic context in India and particularly in Kerala was one of protectionism till the Nineties. There were 900 items reserved for the small sector alone. The economy was liberalized in the early 90s and a number of those items got dereserved. This made the going difficult for the small sector. More over, the environment in Kerala was characterized by frequent labour strikes, high degree of politicization and bureaucratic governance structure. The thrust of the extant government policy has been on price rather than on quality and competitiveness. In spite of the passage of a decade and a half of liberalization, Kerala has not yet geared its macroeconomic policy to keep up with the environment of liberalization. But whatever policy exists also suffers from the problem of path dependence. Cluster policy will have to depart from the beaten track and it is generally found to be difficult. Moreover, it may over lap other policy areas as there is bound to be a wide diversity in cluster policies as engendered by the diverse requirements of the cluster. While general policies focus on the individual firms, cluster policy should address network issues. In other words, the thrust of the policy should be on the importance of networking, the targeting of selected networks and the focus of innovation (Raines, 2002). Though there is much talk about encouraging enterprise clusters, cluster specific policies have seldom been in place. Industrial estates have attracted considerable

attention of policy makers, but estates are qualitatively very different from clusters and the policy support required is also very different. Resource sharing, joint purchase and use of machines, bulk buying of raw materials, sharing of skills etc. are possible if there is networking between the firms. In the Shornur case, if an adequate network is developed, the cluster as a collective unit can bid in the auction for railway scrap and get the raw material at a much lower price than what is paid for now. Also important is the creation of training centers and enhancement of existing facilities such as market and technology information and technology support. After identifying common skill shortage, the centers can design courses appropriate for the workers. Another policy initiative that the government may provide in collaboration with or without the business associations is common facilities and services relevant for the cluster. In this context, the role of creating appropriate supportive institutions needs to be emphasized. In Shornur, a Small Industries Service Institute (SISI) used to offer some amount of technical support to the units in the cluster. In the 90s, it was closed down as part of the government policy to wind up non-profit making enterprises. This was a major set back to the small units in the cluster. Therefore, what is immediately required is the reopening of the SISI as a supporting institution and widening its scope of activities. In all these things what is needed is a more comprehensive and integrated approach to local economic development keeping in view the growing importance of localized policy design and delivery (Nauwelaers, 2001). In Italy, the birth place of industrial districts policy initiatives come from the local governments because only the local government can clearly understand the importance of the local cluster and hence it's various needs. In Kerala, a massive movement was recently launched towards decentralized planning with great success. As much as 40% of the state resources are routed through village panchayats-the local bodies, but there has not been any devolution of policy making powers. If more policy making powers are transferred to the panchayants, probably they could play an important role in fostering the rural clusters in Kerala that could substantially raise output and employment. If an imaginative policy frame can be put in place along with the creation of appropriate institutions, the local bodies could profitably address the problems of inter-firm collaboration, innovativeness and competitive advantage in clusters.

**Table 1: Reasons for Subcontracting**

| Reasons for Subcontracting          | Shornur             | Perumbavoor         |
|-------------------------------------|---------------------|---------------------|
|                                     | Percentage of units | Percentage of units |
| Irregular demand                    | 13.8                | 24                  |
| Savings on premises and machinery   | 45.4                | 50                  |
| Greater efficiency of subcontractor | 9.1                 | 17                  |
| Lower wages of subcontractor        | 22.6                | 9                   |
| Others                              | 9.1                 | 0                   |

**Table 2: Type of Interaction Between Parent Firms and Subcontractors**

| Type of interaction                          | Percentage of Units Reporting |              |             |              |

## **ABSTRACT**

This paper focuses on the business interventions to develop entrepreneurship and new venture creation in South Africa. The high level of unemployment, low economic growth, and the fact that the Global Entrepreneurship Monitor (GEM) report of 2003 ranked South Africa 36<sup>th</sup> out of 40 countries in the world in terms of entrepreneurial activities within established business, emphasizes the importance of entrepreneurship interventions in this field.

Primary data was collected by means of a questionnaire survey sent to a sample of businesses in South Africa. The first phase of the data analysis was to establish business level of agreement with the statements relating to the development of entrepreneurship and new venture creation as identified in academic literature. The results indicated that over fifty percent (50%) of respondents agreed with statements grouped under the following variables: structure, commitment, creativity, and innovation as essential to the development of entrepreneurship and new venture creation. Opinion was divided on the other two remaining variables of strategy and of training and development.

The second phase of the data analysis results' indicated a statistically significant relationship between the main activity/type of the business and the following dependent variables: structure, training and development, and commitment. The results also indicated a statistically significant relationship between the existence of a training department in a business and the following dependent variables: structure, training and development, creativity and innovation. It is recommended that businesses in South Africa adopt a holistic approach that embraces entrepreneurship at all organisational levels. Strategy, training and development need strong emphasis, with unwavering commitment from all levels of management.

## INTRODUCTION

One of the distinguishing features of the current global economy is the increasing evidence of decreasing job opportunities. In developing countries, big businesses tend to have limited success in job creation and the advancement of economic growth. The results of the Job Creation research conducted over 12 million companies in the United States revealed that businesses with fewer than 100 employees created more jobs than those with more than 100 employees (Finley, 1990:4). Timmons (1999:4) reveals that 81.5 percent of the new jobs in the United States were created by new and growing smaller firms as compared to 5 million jobs lost by the Fortune 500 listed companies.

In South Africa, the small, medium and micro enterprises (SMMEs) have created 53.9 percent of the new jobs as compared to 46.1 percent of job opportunities created by large enterprises (Ntsika, 2001:38). Taking into consideration the current unemployment level of 26.2 percent (Stats South Africa, 2004), the average economic growth of 3.2 percent (Budget speech, 2005), ongoing job losses as a result of the closure of gold mines (Bathong & Shone, 2004; Smith, 2005; Annon, 2005), and the restructuring and rationalization that is taking place in both private and public sector, the role of the SMMEs as agents for employment in South Africa cannot be overemphasised, especially within the context of a developing nation.

The trend of decreasing job opportunities explains why most countries all over the world have been searching for solutions to the problem of unemployment over the past decade. This worldwide search has for the past two decades focused on the entrepreneur and his or her ability to contribute to economic growth.

Bridge, O'Neill and Cromie (1998:207) state that governments all over the world are intervening in their countries' economies to promote economic growth and job creation. The South African government is also intervening through the Department of Trade and Industry (DTI), through agencies such as the National Small Business Council (advice the government on social and economic policy that promote the development of SMMEs), Ntsika Enterprise Promotion Agency (delivery of programmes for the support and promotion of SMMEs), Khula Enterprise Financial Limited (whole sale lending institution aimed to improve lending resources for SMMEs), Umsombomvu Youth Fund (provide finance to young emerging entrepreneurs), Business Partners (provide finance to prospective entrepreneurs who engage in start-ups, expansions, take-overs, Management Buy-Outs, Management Buy-Ins, and Leveraged Buy-Outs), and many other independent institutions such as universities and the media.

The success of government interventions depends on business participation in the implementation of intervention policies, engaging in entrepreneurial activities aimed at promoting economic growth and the creation of job opportunities. The research conducted by Tawney and Levitsky (2002) revealed that businesses in Eastern Europe intervened in the

development of entrepreneurship and new venture creation during the 1970 – 95 period of high unemployment, caused by the closure and rightsizing of companies, by engaging in the following activities:

- Assisting in the creation of new businesses initiated by redundant employees.
- Conducting training programmes in business skills.
- Former company employers offered vacated premises, used equipment and guarantees for orders or for bank loans to new small businesses.
- Where there has been a restructuring which has outsourced services or items previously made in-house, arrangements were negotiated for the new small businesses to carry out these operations as subcontractors.
- Large firms provided support to new and expanding small businesses in the form of technical assistance, help in finance, assistance with tools, equipment and premises.
- Management and employees buy out the whole troubled firm to save their jobs and make concession on employment, pay and/or benefits.

In South Africa businesses are promoting entrepreneurship through franchising and Black Economic Empowerment (BEE). According to the Franchise Baseline Census 2002, the franchise industry contributed 11.6 percent to GDP in South Africa in 2001, employed an estimation of 400 000 people, and 60 percent of new outlets went to black franchisees in 2002 (Barnard, 2004). The KPMG/SAVCA survey (2003) revealed that investments in BEE entities increased from R559 million in 2002 to R717 million during 2003.

However, research conducted by the University of Cape Town's Centre for Innovation and Entrepreneurship as part of 2003 Global Entrepreneurship Monitor ranked South Africa 36<sup>th</sup> out of 40 countries for entrepreneurial activity in an established business (Global Entrepreneurship Monitor, 2003). The results of the study conducted by Maritz, du Plessis and Nieman (2004) also revealed that South Africa have the lowest Total Entrepreneurial Activity (TEA) as compared to Australia and New Zealand.

Given the role played by the SMMEs in economic growth and the creation of job opportunities, business interventions to develop entrepreneurship and new venture creation have become a matter of urgency which cannot be ignored, especially since entrepreneurial activity is a prerequisite for the success of economic growth, development, social well-being and political stability (Antonites & Watson, 2004).

## **PROBLEM STATEMENT AND OBJECTIVES**

The results of the 2003 Global Entrepreneurship Monitor (GEM) revealed that South Africa ranked 22<sup>nd</sup> out of 31 countries in terms of new venture creation (Global Entrepreneurship Monitor 2003). Also Maritz, du Plessis and Nieman (2004) reveal an unfortunate situation regarding the development

of entrepreneurship in the country. This situation is particularly problematic as the South African economy is dependent on new ventures creation for economic development and employment.

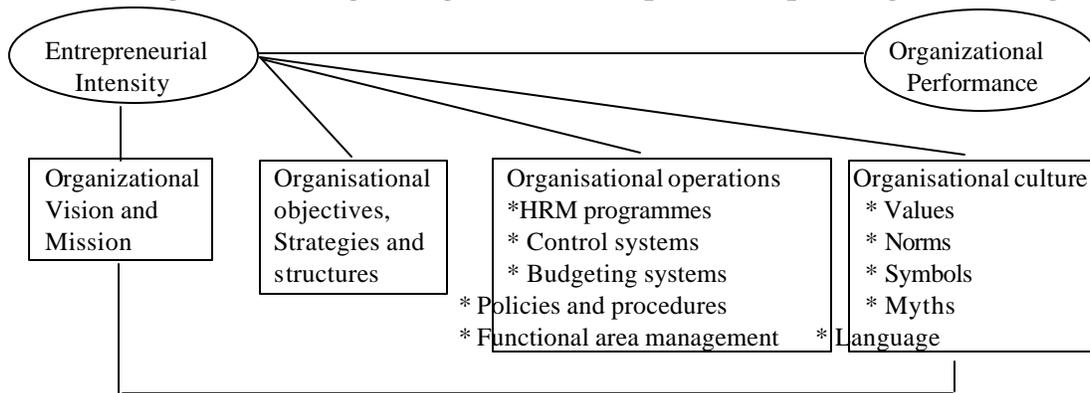

The primary objective of this study was to investigate South African business interventions to develop entrepreneurship and new venture creation.

In this paper a literature review will first be presented. Thereafter the methodology used in the empirical research is outlined. Information on the response rate and the results of the data analysis are provided. The paper concludes with a section that outlines the conclusion of the study and the recommendations thereof.

### LITERATURE REVIEW

In order to investigate business interventions to develop entrepreneurship and new venture creation in South Africa, Morris and Kuratko (2002:34) model of strategic integration of entrepreneurship illustrated in figure 1 was adopted.

**Figure 1: Strategic integration of entrepreneurship throughout the organisation**

**SOURCE: Adapted from Morris and Kuratko (2002:34)**

Figure 1 points out that the entrepreneurial activities of a business can only intensify if entrepreneurship is interwoven in the organisational vision and mission, organizational objectives, strategies and structures, organisational operations, and organisational culture. Figure 1 also illustrates that there is a direct relationship between entrepreneurial intensity and organisational performance. Thus an organisation that embrace the development of entrepreneurship tend to perform better as compared to organisations that do not embrace the development of entrepreneurship.

Taking into consideration that very little empirical study has been conducted in South Africa on business interventions to develop entrepreneurship and new venture creation, the following variables were identified

from Morris and Kuratko (2002:34) model as essential to the study.

### **Strategy**

Sathe (2003:2) argues that strategy provides a good starting point from which to examine corporate entrepreneurship. With a clear strategic intent, the core competence of a business can be effectively leveraged to create new businesses. Thompson and Strickland (1998:5) define a strategic vision as a road map of the business future, showing the direction it is headed, the business position it intends to stake out, and including the capabilities it plans to develop.

Strategy creates a sense of unity, or consistency of action, throughout the business. In order for people to work toward common objectives, they must know what the objectives are. Strategy is about performing different activities from those of competitors, or about performing similar activities but in different ways.

### **Structure**

Hisrich and Peters (1995:35) state that business management structures diverge significantly between the two domains, namely the administrative domain and the entrepreneurial domain. In the administrative domain, the organisational structure is formalised and hierarchical because of the need for clearly defined lines of authority and responsibility based on management theory and a reward system. The entrepreneurial domain must have its independence, and employs a flat organisational structure with informal networks throughout.

As a business designs more hierarchical levels into the organisational structure, the ability to identify market opportunities, achieve management commitment, reallocate resources, take risks, or implement effective marketplace moves becomes problematic. Moreover, hierarchies tend to be accompanied by two other entrepreneurial barriers: top-down management and restrictive channels of communication. The result is frequently intransigence, which leads to a lack of commitment to innovation and change at all levels of the organisation. There is also a tendency to narrow the span of control of managers and to compartmentalise operations as firms mature. The result is over-supervised employees who have little room to be creative or to improvise.

Hall (1996:169) highlights that organisational structures, with their varying sizes, technological sophistication, and degrees of complexity and formalisation, are designed to evolve into information-handling systems. The very establishment of an organisational structure is a sign that communications are supposed to follow a particular path. Research findings of De Coning, Kwinana, Lotter, Munnik and Smit (1997:24) reveal that the communication structure in organisations is an apparent impediment to a black manager's access to entrepreneurial power.

Open and honest communication is such a vital co-producer of entrepreneurial organization that it is considered its heart, and it is very difficult to imagine suitable access to entrepreneurial power without it. Bureaucratic practices often frustrate employees who have innovative ideas, so that employees often

keep their innovative ideas to themselves. Instead of encouraging innovation and creative thinking among organisational employees, many organizational structures unintentionally stifle it. Entrepreneurial organisations should have flattened organisational reporting structures in order to facilitate the smooth flow of communication/ information.

### **Training and development**

HRM policies are a reflection of a business culture, whether entrepreneurial or not (Morris and Kuratko, 2002:239). With such rapid changes in technology and the rate at which new products are introduced, achieving a sustainable advantage in the new competitive landscape requires managers to constantly empower their employees through training and development. Coetsee (1996,42) define empowerment as the provision of opportunities for employees to assist with the identification of problems, the defining thereof and inviting their inputs in decisions on how work should be done, how work methods could be improved and the delegating of more comprehensive powers and responsibilities.

Training and development programmes can be used as a vehicle for the development and operationalisation of entrepreneurship in an organisation. Training and development programmes afford employees the opportunity to engage in continuous individual learning to ensure life-long learning in the organisation.

The presence of research and development departments (R&D) in a business offers an excellent opportunity to prospective entrepreneurs to inculcate the spirit of innovation if given the opportunity. It is therefore important for businesses to involve as many people as possible in their R&D so as to nourish an entrepreneurial spirit among its employees.

### **Commitment**

Morris and Kuratko (2002:239) state that entrepreneurship requires a culture built around emotional commitment, autonomy, empowerment, sincere respect and strong work ethic.

Sathe (2003:222) argues that management culture has a major influence on new business creation.

Gerber (1995:26) describes the tension between management and the entrepreneur as follows:

- The entrepreneur lives in the future, the manager lives in the past. When the entrepreneur craves control, the manager craves order.
- Where the entrepreneur invariably sees the opportunity in events, the manager invariably sees problems.

Coetsee (1996:39) define commitment as ownership or full identification. If entrepreneurship is to be realized in a business, top managers should take ownership of the development programmes and display total dedication towards successful implementation of such programmes. The commitment of

leadership to developing and sustaining entrepreneurship in a business has the potential to help transform the organisation and unleash talent.

### **Creativity and innovation**

Creativity and innovation are essential components of entrepreneurship. Zeelie, De Beer, Jacobs, Rossouw, Stapelberg, Watson and Niewenhuizen (1998:140) define creativity as the generation of new ideas. Drucker (2001:22) defines innovation as the act that endows resources with a capacity to create wealth. Creativity leads to innovation. To innovate is to introduce within a company or marketplace new methods, processes, technologies, products or services (Morris & Kuratko, 2002:121). Creativity is a person's imagination and his or her ability to think of something original, while innovation refers to the use of creative abilities to create something (Zeelie et al, 1998:10).

Wickham (2001:218) and Sadler (2002:197) suggest that for creativity to flourish in a business, an entrepreneur does not have to rely on his or her own creativity. He or she should recognise, value and champion the creativity of others. This can be achieved by establishing a creative group within the business consisting of product experts, and encouraging them to think about the needs of a particular market and consider how those needs might be better served.

According to Timmons (1999:13), the advantage of using teams is that they can generate the creativity that a single person may not be able to generate. Using teams to generate creativity therefore gives more people the opportunity to develop entrepreneurial skills. Bridge et al (1998:47) stresses that creativity is enhanced when people have some freedom, a high internal commitment to the task, and many intrinsic rewards.

Drucker (2001:148) points out that policies, practices and measurements need to be put in place to facilitate positive entrepreneurship and innovation. If an existing business is to innovate, it has to create a structure that allows people to be entrepreneurial. It has to devise relationships that lead to the development of entrepreneurship. It has to make sure that its rewards and incentives, its composition, personnel decisions and policies, all reward the right entrepreneurial behaviour and do not penalise it.

## **DESIGN AND METHODOLOGY OF THE EMPIRICAL STUDY**

There is an absence of a comprehensive sample frame of small businesses in South Africa. As such, probability sampling was used to select a stratified sample total of 1000 businesses drawn from a list of businesses kept in a register by the Bureau of Market Research (BMR) of the University of South Africa (Unisa). The Bureau of Market Research (BMR) keeps different types of registers of businesses in a specific sector of the economy which are updated on an ongoing basis. The stratified sample was drawn from different types of businesses, based on the criteria laid down by the National Small Business Act (National Small Business Act No. 102, 27 November 1996). The sample consisted of the following businesses: manufacturing (50%), mining (10%), wholesalers (10%), retailers (10%), services (10%), and importers and exporters (10%).

### **The Measuring Instrument**

The questionnaire used in this survey consisted of two sections. Section A consisted of forty-four (44) questions/statements phrased with a possible response continuum, linked to a Likert-type five-point scale where 1 meant “strongly disagree”, and 5 “strongly agree”.

Respondents were to indicate the level of agreement with statements relating to the development of entrepreneurship and new venture creation. Levels of agreement with each statement were measured by taking the proportion of respondents who marked four (4) or five (5) on the five-point Likert-type scale. A four (4) meant that the respondents agreed with the statements, and a five (5) meant that the respondents agreed strongly with the statements.

To ensure validity, the questions/statements were tested by conducting a pilot study. The pilot survey involved twenty (20) businesses in the Ekurhuleni Metropolitan Area, Gauteng province, in South Africa. The businesses were chosen so as to be representative of the actual business to be surveyed.

Section B requested demographic/classification information such as the main activity/type of the business, the number of employees in the business, the current market share within the industry, the existence of a training department in the business, and the use of an outside consultant. One thousand (1000) questionnaires were sent out by mail.

### **DATA ANALYSIS**

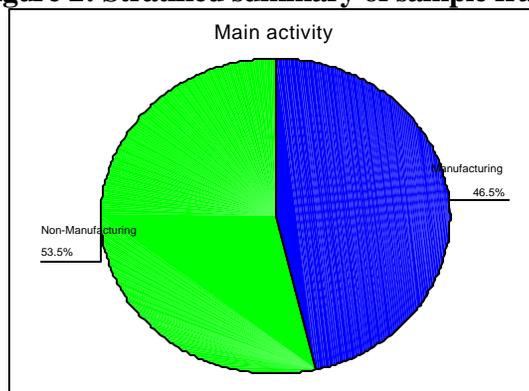

Data analysis relating to reported results was conducted in the following two stages:

- Firstly, in order to verify the internal reliability of the measuring instrument, Cronbach's alpha coefficients were calculated following (Emory & Cooper, 1991:187). Reliability coefficients 0.50 were deemed unacceptable, and those above 0.70 acceptable (Nunally, 1978:226).
- Secondly, descriptive statistics such as the frequency distribution, mean and the standard deviation were calculated to assess the level of agreement in South African businesses with statements relating to the development of entrepreneurship and new venture creation.
- Finally, inferential statistics were used to search for statistically relationships between the dependent variables (structure, strategy, training and development, commitment, creativity, and innovation), and the independent variables (the nature/type of the business, and the existence of a training department in the business).

Of the one thousand (1000) questionnaires posted to potential respondents, only two hundred and fifteen (215) were returned fully completed, thus achieving a response rate of 21.5 percent. The businesses that returned the questionnaires were manufacturing (46.6%), engineering (7.9%), importers and exporters (1.2%) mining (7.4%), wholesalers (6.0%), retailing (10.2%), business services (12.6%) and others (8.4%). Due to the small percentages of responses in some of the

business classifications, for analysis purposes, the businesses were reclassified as illustrated in figure 2.

**Figure 2: Stratified summary of sample frame**

This implies that more than half of the respondents (53.5%) are businesses whose main activity/type is non-manufacturing related (ie retailers, wholesalers, services and others), while the rest of the respondents (46.5) are classified as manufacturing. The information collected may thus be deemed representative of South African business as a whole.

## EMPIRICAL RESULTS

### Internal reliability assessment

Internal reliability results obtained Cronbach’s alpha are summarised in table 1.

**Table 1: Summary of Cronbach’s alphas**

| Statement groupings      | Cronbach’s alphas |
|--------------------------|-------------------|
| Strategy                 | 0.71              |
| Structure                | 0.76              |
| Training and development | 0.73              |
| Commitment               | 0.76              |
| Creativity               | 0.81              |
| Innovation               | 0.77              |

This table reveals that all the calculations of the Cronbach alphas are in excess of 0.70. The measuring

instrument can thus be regarded as reliable. The next step of the analysis was to assess the level of agreement with the statements relating to the development of entrepreneurship and new venture creation.

### **Findings on the level of agreement with statements relating to the development of entrepreneurship and new venture creation**

Table 2 depicts the descriptive statistics results.

**Table 2: Results of descriptive statistics**

| <b>Variable/statements</b> | <b>No. of respondents</b> | <b>% of agreement</b> | <b>Mean</b> | <b>Standard deviation</b> |
|----------------------------|---------------------------|-----------------------|-------------|---------------------------|
| Creativity                 | 215                       | 74.9%                 | 4.0         | 0.88                      |
| Innovation                 | 213                       | 70.7%                 | 3.81        | 0.89                      |
| Commitment                 | 213                       | 67.4%                 | 3.73        | 0.96                      |
| Structure                  | 212                       | 55.7%                 | 3.45        | 0.95                      |
| Training and development   | 214                       | 47.0%                 | 3.41        | 1.10                      |
| Strategy                   | 213                       | 46.9%                 | 3.28        | 0.99                      |

The results indicate that the mean scores vary for all variables identified as essential for the development of entrepreneurship and new venture creation. The highest mean score was allocated to the variable creativity (mean = 4.0). The vast majority of the respondents (74.9%) agreed with the strategy of fostering the spirit of creativity in the organization the statements. Mostly, respondents includes, agreed with the strategies of encouraging employees to seek and follow strategies that result in customer satisfaction (mean = 4.09), encouraging employees to be creative in their jobs (mean = 4.05), encouraging pro-activeness in all organizational level (mean = 4.0), encouraging greater employees participation in the identifying of new product or service, and encouraging employees to come up with new ideas of doing things (mean = 4.00).

Innovation followed with a mean score of 3.81, and thus achieving the level of agreement of 70.7%. Most of respondents indicated that they implement the following innovation policies: they understand the process of satisfying customers in innovative ways (4.31), they are committed to establish the spirit of innovation in all organizational level (mean = 3.85), they have set specific goals for innovation of new products/services in the market place (mean = 3.81), and have set specific innovation objectives for each department (3.37).

Commitment from management to develop entrepreneurship and new venture creation obtained a

mean score of 3.73. The extent to which respondents agrees with the level of commitment is 65%. Respondents agreed with statements that they are committed to economic growth (mean = 4.39), and that they are committed to the development of entrepreneurship (mean = 3.37).

Structure obtained a mean score of 3.45, and thus achieving the level of agreement of 55.7%. Most of the respondents agreed that the reporting structure in their businesses are user friendly for both employees and managers (mean = 3.61), they have a reporting structure that is process based (mean = 3.79), has a reporting structure that cuts across all levels in order to maximize opportunity identification (mean = 3.45), and the communication structure that is both top-down and bottom-up (mean = 3.04).

Training and development obtained the mean score of 3.41, and the level of agreement of 47%. Respondents agreed with the statements that they are involved in programmes that develop entrepreneurship (mean = 3.20), strive to improve the effectiveness of the business through the development of entrepreneurship (mean = 3.42), has a learning strategy to encourage entrepreneurship (mean = 3.21), develops entrepreneurship through effective training (mean = 3.02), regards training to be equivalent to learning (mean = 3.77), and offers Internship to young graduates who wish to gain practical experience in running a business (mean = 3.97).

Strategy as a variable for the development of entrepreneurship and new venture creation obtained the lowest mean score of 3.28, and the level of agreement of 46.9%. The most common statements agreed upon by respondents are: they are guided by a clearly defined mission (mean = 4.05) and, provision is made in the annual budget for workshops aimed at developing entrepreneurship (mean = 2.89).

### **Relationships between the main activity of the business and variables essential for the development of entrepreneurship**

The analysis of variance (ANOVA) and the independent t-test group statistics was undertaken to determine whether statistically significant relationships exist between independent variables and the dependent variables. Table 3 depicts the results of the t-test group statistics.

**Table 3: Results of the t-test group statistics of independent and dependent variables**

| <b>Dependent variables</b> | <b>Independent Variables</b> | <b>No. of Employees</b> | <b>Mean</b> | <b>Standard Deviation</b> | <b>Standard error mean</b> |
|----------------------------|------------------------------|-------------------------|-------------|---------------------------|----------------------------|
| Strategy                   | Manufacturing                | 94                      | 3.151*      | 0.627                     | 0.849                      |
|                            | Non-manufacturing            | 110                     | 3.371*      | 0.695                     | 0.663                      |
| Structure                  | Manufacturing                | 89                      | 3.366       | 0.558                     | 0.069                      |
|                            | Non-manufacturing            | 108                     | 3.431       | 0.558                     | 0.054                      |
| Training and development   | Manufacturing                | 95                      | 3.319*      | 0.588                     | 0.080                      |
|                            | Non-manufacturing            | 110                     | 3.660*      | 0.582                     | 0.066                      |
| Commitment                 | Manufacturing                | 98                      | 3.608*      | 0.662                     | 0.067                      |
|                            | Non-manufacturing            | 107                     | 3.837*      | 0.632                     | 0.061                      |

|            |                   |     |       |       |       |
|------------|-------------------|-----|-------|-------|-------|
| Creativity | Manufacturing     | 97  | 3.833 | 0.591 | 0.059 |
|            | Non-manufacturing | 115 | 3.919 | 0.653 | 0.601 |
| Innovation | Manufacturing     | 96  | 3.846 | 0.677 | 0.059 |
|            | Non-manufacturing | 110 | 3.777 | 0.642 | 0.061 |

\* Difference in mean values

The results of the t-test as illustrated in table 3 reveal differences in the mean scores between manufacturing and non-manufacturing businesses in the following variables: strategy (3.151; 3.371), training and development (3.319; 3.660), and commitment (3.608; 3.837). To further establish the relationship between the dependent and independent variables, a t-test for equality of means was conducted of which the results are illustrated in table 4.

**Table 4: Results of the t-test for equality of means of independent and dependent variables**

| Dependent variable              | T       | Df      | Sig. (2-tailed) | Mean difference | Standard error Difference | 95% confidence interval of the difference |         |
|---------------------------------|---------|---------|-----------------|-----------------|---------------------------|---|---------|
|                                 |         |         |                 |                 |                           | Lower                                     | Upper   |
| <b>Strategy</b>                 |         |         |                 |                 |                           |   |         |
| Equal variance Assumed          | - 2.356 | 202     | 0.019*          | - 0.219         | 0.093                     | - 0.404                                   | - 0.359 |
| Equal variance Not assumed      | - 2.376 | 201.394 | 0.018*          | - 0.219         | 0.093                     | - 0.402                                   | - 0.037 |
| <b>Structure</b>                |         |         |                 |                 |                           |   |         |
| Equal variance Assumed          | - 0.667 | 196     | 0.572           | - 0.045         | 0.079                     | - 0.203                                   | 0.112   |
| Equal variance Not assumed      | - 0.667 | 187.863 | 0.572           | - 0.045         | 0.079                     | - 0.203                                   | 0.112   |
| <b>Training and Development</b> |         |         |                 |                 |                           |   |         |
| Equal variance Assumed          | - 2.813 | 203     | 0.005*          | - 0.230         | 0.082                     | - 0.392                                   | - 0.069 |
| Equal variance Not assumed      | - 2.811 | 198.080 | 0.005*          | - 0.230         | 0.082                     | - 0.392                                   | - 0.089 |
| <b>Commitment</b>               |         |         |                 |                 |                           |   |         |

\*Significant level at 0.05

The results of table 4 indicate a significant relationship in the following three variables: strategy (p-value 0.019), training and development (p-value 0.005) and commitment (p-value 0.012). Since the mean differences between manufacturing and non-manufacturing businesses is not that significant, it can be concluded that entrepreneurship can be developed in any nature/type of a business. Strategy, training and development, and commitment are key variables essential for the development of entrepreneurship and new venture creation in any nature/type of a business.

### **Relationship between the existence of a training department in a business and the variables essential for the development of entrepreneurship**

The majority of the respondents (61.7%) indicated that their businesses has a fully developed training department, 37.4 percent indicated that there exist no training department in their business, and 0.9 percent can be regarded as neutral or indifferent. The results of the analysis of variance (ANOVA) and the t-test undertaken are for this category are depicted in table 5 and table 6.

**Table 5: Results of the t-test group statistics for independent and dependent variables**

\*Significant level at 0.05

The result of the t-test analysis represented in table 5 reveals differences in the mean values of the following variables: structure, training and development, creativity and innovation. The t-test for equality of means as depicted in table 6 revealed a significant relationship in the

following four variables: structure (p-value 0.007), training and development (p-value 0.043), creativity (p-value 0.013) and innovation (p-value 0.000). It can therefore be concluded that the existence of a training department in a business has a positive influence towards the development of entrepreneurship and new venture creation.

## **CONCLUSION AND RECOMMENDATIONS**

Considering the fact that South Africa faces the problem of high unemployment and slow economic growth and that South Africa rank 36<sup>th</sup> out of 40 countries in the world in terms of entrepreneurial activities in established businesses, this study offer an alternative model that can be used to improve the status of business involvement in entrepreneurial activities.

The study shows that strategy, training and development, and commitment by management are key essential components for businesses to become entrepreneurial. Achieving sustainable advantage in the new competitive landscape requires managers to think and act strategically, and to formulate appropriate entrepreneurial strategies. Thus strategic planning is the primary step in anticipating and managing entrepreneurship in any business venture. A strategy, in essence, attempts to capture where the business wants to go and how it plans to get there. When entrepreneurship is introduced to strategy, the possibilities for where the business can go, and how far it can go towards getting there, are greatly enhanced.

With such rapid changes in technology and the rate at which new products and services are introduced, achieving a sustainable advantage in the new competitive landscape requires managers to constantly empower their employees through training and development. Training and development programmes in a business have a considerable influence on employee performance. A business that invests in training programmes as an empowerment vehicle will be better able to improve productivity than a business that does not invest in its employees.

The existence of a training department in a business creates a favourable environment for the implementation of training and development programmes, whereby employees are exposed to both a formal and an informal learning environment. It therefore follows that creativity and innovation will be favoured in such an environment because employees will get the opportunity to unleash their potential and become more productive. Having a training department in a business will also ensure the life-long learning of an organisation.

Changing job demands and the need to keep abreast of the newest technologies suggest a need for ongoing training. Training and development empower employees to be able to respond in a unique ways to new challenges, and to adapt to dynamic environmental conditions. Training and development should not only be limited to employees in a business, but should be extended to include external prospective entrepreneurs through internship and learnership.

Interns can be exposed to start-up businesses, high-growth businesses, or nonprofit organisations seeking innovative and entrepreneurial solutions, and thus expose them to real-life challenges. This way interns get a good opportunity to enhance entrepreneurial classroom education with the practical perceptions that can only come from confronting real entrepreneurial challenges.

Commitment is the nucleus that leads to the success of any undertaking. There cannot be any change in the direction of the business, unless management is committed to change. The results of the survey showed that respondents agreed strongly that traditional management style is no longer good enough for business success. A transformational leader who moves with the times, faces the challenges, and steers the business towards the changing competitive landscape is required. It takes a committed leader who is willing to take risks to tackle the challenges that are brought about by the changing market to respond accordingly, and engage in entrepreneurial activities that will keep the business abreast with their competitors.

It is therefore recommended that businesses in South Africa adopt a holistic approach that embraces entrepreneurship in all organisational levels as outlined in Morris and Kuratko (2002:34) model. Strategy, training and development need strong emphasis, with unwavering commitment from all level of management.

## ABSTRACT

Scholars and researchers in entrepreneurship have reported that small business management and entrepreneurship courses at both the 2 and 4-year college and university levels have grown in the number and diversity of course offerings from 1990-2004. This expansion of educational offerings has been fueled in part by dissatisfaction with the traditional Fortune 500 focus of business education voiced by students and accreditation bodies (Solomon & Fernald, 1991). The dilemma is not that demand is high but that the pedagogy selected meets the new innovative and creative mindset of students. Plaschka and Welsch (1990) recommend an increased focus on entrepreneurial education and more reality and experientially-based pedagogies such as those recommended by Porter and McKibbin (1988). The challenge to educators will be to craft courses, programs and major fields of study, meeting the rigors of academia while keeping a reality-based focus and entrepreneurial climate in the learning experience environment. One demand is that they must be able to initially recognize a potential opportunity, as a precursor to further behavior. The process that opportunity recognition entails can foretell the success or failure of a new venture – it is a crucible. There is a burgeoning body of literature in the young field of entrepreneurship and entrepreneurship education; however, little research exists regarding the specific competency of opportunity recognition, and even less of the research is empirical in nature.

## INTRODUCTION

The purpose of this paper is to review the entrepreneurship education literature to explore current thinking regarding entrepreneurs and the competencies necessary for success, and will investigate the opportunity recognition competency specifically. Models of the opportunity recognition process, creativity literature, and pedagogical methodologies will also be the subject of inquiry, along with their theoretical underpinnings. This paper will search for relationships between concepts and proposals for how we might best prepare students to follow their entrepreneurial dreams.

The entrepreneurial experience can be characterized as being chaotic and ill-defined, and our entrepreneurship education pedagogies should reflect this characterization. In addition, we often make the assumption that it is relatively easy for entrepreneurship students to develop new ideas for their business start-ups. Quite a number of researchers have written about entrepreneurial competencies; however, the competencies that are required for new business start-ups are often

addressed by educators in an ad-hoc manner. There is little consensus on just what exactly entrepreneurship students should be taught.

For entrepreneurship educators, the challenge is to provide the subject matter, resources, and experiences that will prepare entrepreneurship students to cope with the myriad of expectations and demands they will face as they start their new ventures. One demand is that they must be able to initially recognize a potential opportunity, as a precursor to further behavior. The process that opportunity recognition entails can foretell the success or failure of a new venture – it is a crucible. It would seem apparent, then, that adequate attention should be given to the pedagogies addressing this competency. There is a burgeoning body of literature in the young field of entrepreneurship and entrepreneurship education; however, little research exists regarding the specific competency of opportunity recognition, and even less of the research is empirical in nature.

## **METHODOLOGY**

For purposes of this paper, literature was reviewed from the proceedings of entrepreneurship and management conferences; indices and tables of contents of entrepreneurship, management, and creativity journals; online library databases; and online listings of entrepreneurship education courses and textbooks. The field of entrepreneurship education is a relatively young one (Sexton, 1982). Since the 1970's, there has been a huge increase in the number of articles written (for example, the USASBE online Bibliography lists 2,073 items for "Entrepreneurship Education"). The resources used primarily were those that specifically dealt with cognitive and learning needs, curriculum development and pedagogy.

## **ENTREPRENEURSHIP EDUCATION**

As we delve into the literature on entrepreneurship education, it would be helpful to define what we mean by "entrepreneurship education." Shepherd and Douglas (1997) propose:

The essence of entrepreneurship is the ability to envision and chart a course for a new business venture by combining information from the functional disciplines and from the external environment in the context of the extraordinary uncertainty and ambiguity which faces a new business venture. It manifests itself in creative strategies, innovative tactics, uncanny perception of trends and market mood changes, courageous leadership when the way forward is not obvious and so on. What we teach in our entrepreneurship classes should serve to instill and enhance these abilities.

We have seen an increase in entrepreneurship education programs, and research will likely continue as the field matures. Unfortunately, as reported by Gorman, Hanlon, & King (1997), "there is little uniformity in the programs offered, especially if one considers the relative similarity of other business programs" (p. 70), a topic to be explored in the next sections.

### **Overall "Essence" of Entrepreneurship Education:**

Entrepreneurship education programs exist, most generally, within established university business schools, and this presents a paradox that helps to explain the above-mentioned lack of uniformity in curriculum and pedagogies. Traditional business programs have come under increased criticism for failing to be relevant to the needs of today's changing business environment (Brown, 1999). One common criticism is that business education has become too functionally oriented – that it doesn't stress the cross-functional complexity of business problems. Other criticism focuses on the "lack of creativity and individual thinking required at both undergraduate and graduate levels" (Solomon, Fernald, & Weaver, 1993). Sexton and

Bowman (1984) note that most business school courses are highly structured and do not often pose problems which require novel solutions.

Even entrepreneurship courses fall into a left-brain-oriented trap. Bird (2002) describes many core entrepreneurship courses:

...require students to write and present a business plan and often students (in teams limited to fellow classmates who may not be rationally chosen as partners) choose the business concepts to pursue...Problems are presented and time frames for solving them given. There is often the illusion or reality of “right answers” (p. 217).

It is also quite common for entrepreneurship classroom situations to focus heavily on theory – “either management theory being adjusted to give advice for entrepreneurship and small business – or entrepreneurship theory explaining the emergence of entrepreneurs and their personal traits” (Blenker, Dreisler, Kjeldsen, & Meibom, 2003). Others echo this concern by noting that entrepreneurship programs often educate “about” entrepreneurship rather than educate “for” entrepreneurship (Kirby, 2003). The essence of entrepreneurship education, then, must reflect reality.

Garavan and O'Conneide (1994) suggest that the best methods suited to an entrepreneurial learning style are active-applied and active experimentation (p. 10), and these also include concrete experience, reflective observation, and abstract conceptualization (Davies & Gibb, as cited in Garavan et al., 1994). In short, “educational programs and systems should be geared toward creativity, multidisciplinary and process-oriented approaches, and theory-based practical applications. What is needed is a more proactive, problem-solving and flexible approach rather than the rigid, passive-reactive concept, and theory-emphasized functional approach” (Plaschka & Welsch, 1990, p. 61).

### **Pedagogy: Teaching for Competencies:**

Competency can be defined as an underlying characteristic of a person, which results in effective and/or superior performance in a job (Boyatzis, as cited in Bird, 2002; Spencer & Spencer, as cited in Bird, 2002). As in previous sections, there is little agreement in the field about the competencies or capabilities that are most valuable for aspiring entrepreneurs to learn.

Entrepreneurial educators teach for competencies; their syllabi reflect their beliefs and academic disciplines. Fiet (2000), for example, examined the syllabi of 18 entrepreneurship courses and found they covered 116 different topics; however, topics do not always reflect competencies (e.g., family business). Plaschka et al. (1990) note that “many programs are evolving on a trial and error or as needed basis, depending on the types of entrepreneurial projects currently undertaken in the program and on the feedback of students experiencing deficiencies, gaps, and difficulties in their courses. These are not necessarily poor approaches to program development...” (p. 66).

Quite a number of researchers have written about entrepreneurial competencies, and we chose several articles to see if there were any commonalities in competencies across authors.

Insert Table 1 here

---

This was not meant to be a comprehensive list of competencies; in fact, it could be argued that some of the above mentioned are perhaps not behaviors at all, but traits. It is interesting to note

that the two competencies above, that were cited most often, are Creativity and Opportunity Recognition. In the 1999-2000 National Survey of Entrepreneurship Education (Solomon, Duffy, & Tarabishy, 2002), when respondents were asked what types of courses they were offering in their educational institutions, only 4% of respondents stated they offered a Creativity Management course. Relf (1995) states: “The intense need for American firms to become more competitive have heightened the need for an increase in creativity to develop new products, new services, and better ways of delivering existing goods and services. Isn’t it astonishing that in most curricula, creativity is absent?”

The literature exploring opportunity recognition and its counterpart, creativity, will be discussed in the following sections.

### **ENTREPRENEURIAL OPPORTUNITY RECOGNITION**

The topic of opportunity recognition is an important one; after all, it represents the foundation of a new entrepreneurial venture. A review of the literature in this area leads us to such rubric as intuition, alertness, intentionality, cognitive processing, personality traits, innovation, and creativity, among others; most of it is descriptive and definitional. The authors of this literature often define the concept, expand upon it, and then tell us how important the topic is to the discipline.

We believe the reason for a lack of consensus is that the entrepreneurship discipline doesn’t have unified definitions of many entrepreneurship concepts, including “opportunity recognition.” In the literature, opportunity recognition is proposed as *the* process or the *outcome* of the process, when it is possible, we believe, that *opportunity recognition is only part of a process – the creativity process*. Intuition, alertness, intention, and the other concepts mentioned above, are *components* of the creativity process.

Singh, Hills, and Lumpkin (1999) define opportunity recognition as “an activity that can occur both prior to firm founding and after firm founding throughout the life of the firm.” Although defining entrepreneurs, Chia (1996) also gives us a good description of opportunity recognition:

Etymologically, the term “entrepreneur” derives from two terms, *entre*, meaning to “enter” or to “penetrate in between” and *prendre* or *prehendere*, meaning to “grasp” or “seize hold of.” Therefore, the entrepreneur is one who *penetrates* the spaces between established boundaries and *seizes* opportunities that are otherwise overlooked by others (p. 413).

There is diverging literature about when opportunity recognition occurs. On one hand, some researchers suggest that opportunities are “discovered.” Koller (1988), for example, showed that “most entrepreneurial ideas seem to be recognized as they appear rather than actively sought out” (p. 203). In another study, Beattie (1999) reported that many of the entrepreneurs he interviewed “picked up opportunities rather than ideas, and were then able to convert the opportunities into ideas” (p. 146).

On the other hand, quite a number of researchers are calling opportunity recognition a process. It is the authors’ contention that opportunity recognition is actually part of a larger process, which will be discussed later in this paper.

#### **Models of Opportunity Recognition Process:**

Notwithstanding researchers who have proposed that opportunity recognition is a stand-alone “aha” moment, it is apparent that this is a process. In a more generic sense regarding the creative process:

Perhaps the creative process unfolds as the developmental sequence of

representational changes, from vague, syncretic, and implicit forms of knowledge into more differentiated, integrated, and explicit ones. In more technical terms, it is conceivable, at least, that the creative process might operate as a developmental translation - -from an implicit code of associative strengths among neural units into an explicit code of symbolic rules. In this cognitive system, implicit neural networks might precede and constrain the generation of symbolic rules (Policastro, 1995, p. 110)

In 1984, Long and McMullan proposed a model of the opportunity identification process with four stages: first, is a pre-vision stage which involves both uncontrollable and controllable factors that set a person up for opportunity discovery; second, is a “point of vision” – much like the “aha” moment of discovery; third, is an “opportunity elaboration” stage to “fill in the gaps and overcome anticipated problems” with the idea; and the fourth stage is a “decision to proceed.”

Hills, Shrader, and Lumpkin (1999) suggest that opportunity recognition is a special case of the creativity process. They used Wallas’ (1926) four-stage\* creativity process model as the basis for their opportunity recognition process model:

1. Preparation: At this first stage, the problem solver begins to gather information about the problem to be solved. Hills et al. note that this stage also refers to the background and experience that an entrepreneur brings to the opportunity recognition process.
2. Incubation: In this stage, gathering more information will be counterproductive. Efforts to solve the problem must be abandoned and allowed to sink into the unconscious mind. This appears to be a “mulling over” period, where the thinker has put the problem on the conscious back shelf for the moment. Hills et al. suggest that this period is typically unconscious, and is an intuitive, non-linear, non-intentional style of considering options.
3. Insight: Wallas referred to this style as the Illumination stage. In this stage, the problem solver suddenly experiences insight into the problem – it is the “Aha!” experience. Hills et al. suggest that there may be three different insights with regard to entrepreneurs: (1) is the experience of spontaneous recognition of a business; (2) would be the occasion when a person gets the idea that solves a problem that he or she has been pondering; and (3) is that it represents the moment when an idea becomes available to the entrepreneur via his/her social network (p. 218).
4. Evaluation/Verification: This stage is when the thinker tries and checks the solution. It involves research into whether a concept will work, whether the thinker has the skills necessary, and whether it is truly novel. Hills et al. note that this is the feasibility analysis stage for entrepreneurs.
5. Elaboration: This is the stage when the creative idea is actualized, or put into a form ready for formal presentation. Hills et al., propose that this is stage represents the process of business planning.

\* Note: Wallas’ creativity model only included the first four stages; subsequent researchers, however, often included the last stage or some variation that Hills et al. have used.

Hills et al. further note that “opportunity recognition” is a staged process that involves the possibility of feedback loops from the moment of insight or the results of evaluation to greater preparation and ongoing incubation (p. 223).

## DISCUSSION AND CONCLUSION

It would appear that entrepreneurs need certain competencies in order to enhance the probability of success of their new ventures, and one of those competencies is opportunity recognition. Opportunity recognition is primarily a cognitive process that most likely can be enhanced with training, and one of the purposes of education is to increase desired behaviors. If we look at the problem from that simplistic level, it would be possible that focused entrepreneurship education could increase the degree of the opportunity recognition competency, and hence, behavior.

Opportunity recognition is an important component of the entrepreneurial process, and it appears to be receiving some increased attention in the last few years. It can be a little daunting trying to get a picture of the process, however, because there are what appears to be a multitude (relatively speaking) of voices telling us how important opportunity recognition is, what it is, and how it works. It is this “how it works” that can be particularly confusing when we read about intuition, alertness, awareness, intention, and so on. Hills et al. (1999) had it correct when they stated that opportunity recognition is a special case of the creativity process. All creativity could be said to have the goal of opportunity recognition; in the case of entrepreneurs, the goal may or may not lead to a new venture.

Below is a proposed working model of the entrepreneurial creative process:

Insert Figure 1 here

---

It is based on systems and cognitive theories, as well as Wallas’ theory of the creative process. The individual brings knowledge, skills/abilities, and experience (which includes memory) to the creative process. The creative process will not be reiterated here in great detail because it was discussed in the models of the opportunity recognition process above; however, additional comments are below:

- **Problem Discovery:** This stage has been separated from Wallas’/Hills et al. models, because the entrepreneur is alerted to a potential opportunity. This has also been called “problem finding,” or as Amabile (1996) calls it, “problem or task identification.” The individual is relatively passive at this stage, in terms of cognitive processing.
- **Preparation:** Focused attention, researching, intuition and intention all play a part in this stage. The entrepreneur begins “doing the research” – whether consciously or unconsciously, formally or informally. In other words, environmental scanning begins during this stage.
- **Incubation:** During much of this stage, the entrepreneur consciously engages in associations and patterning (this is where this model most differs from previous models). At this stage, divergent thinking is evident. This can be an uncomfortable time for the entrepreneur, as the cognitive processing can become almost overwhelming for the entrepreneur. It is towards the end of this stage, that the entrepreneur’s unconscious takes over; he or she unconsciously continues the cognitive processes to search for the answers he/she requires. Even though the entrepreneur has put the process “on the back shelf” as stated earlier, the unconscious processing continues.
- **Illumination:** It is during this stage that insight, or opportunity recognition, occurs. *In this model, opportunity recognition is synonymous with the “Aha!” moment.* Convergent thinking begins.
- **Verification:** This is the stage in which the entrepreneur does a formal (and indeed, informal in many cases) feasibility evaluation. The Formal Business Plan would ideally be the

outcome of this process; in any case, if the entrepreneur decides that the opportunity is a viable one, he or she begins the process of start-up.

The process in this model appears linear; it isn't. There is constant reiteration and feedback during the process (thus, the multiple arrows from feedback on the model). All of the capabilities or competencies that have been proposed as being important to opportunity recognition are included in this model. At any time during the process, the entrepreneur may decide that the opportunity isn't a good one, there aren't resources available, or the time isn't right. The social and economic environment also affects and is affected by the process; it is shown as a cloud because it is always changing. Because it is never static, it exerts differing amounts of pressure on the process. This process model does not take into account, "serendipity." Some researchers (e.g., DeTienne & Chandler, 2004; Martello, 1995) note that many discoveries appear to occur randomly or by chance. However, the entrepreneur will still go through the creativity process to cognitively determine an idea's potential viability.

Little research has been done to date dealing with entrepreneurial behavior once entrepreneurship education has been completed – and for good reasons. Since the discipline of entrepreneurship is a young one (relative to many other fields), we are not seeing rapid convergence towards a unified theory of entrepreneurship, much less agreement on necessary competencies. Measurement issues are still major roadblock. For example, do we continue to interview or survey nascent entrepreneurs, with the related reliability and validity problems that can ensue? We have seen, in the creativity training area, just such difficulties. In the area of innovation, we are beginning to see research using number of patents or new products developed as measurement tools, but that has inherent drawbacks as well.

If opportunity recognition is a part of the creative process, as the model above proposes, it may have implications for entrepreneurship education in this area. Perhaps we should be refocusing our attention on creativity as the competency. Even though the findings for the efficacy of creativity training are not overwhelming, it would appear that progress is being made for prescriptive approach to pedagogies in this area. Specifically, we propose that entrepreneurship educators consider the following when designing their entrepreneurship courses and programs:

- Stop focusing solely on entrepreneurial functional processes (after all, these are not totally different from the functional business courses that students already receive).
- Include an introductory creativity course in their entrepreneurship program.
- Introduce creativity and the use of heuristics experientially throughout their courses.
- Relate the results of creativity experiments to specific and generalizable situations in the entrepreneurial experience.

This can also have implications for future avenues of entrepreneurship study. For example, are the creative training research and training methodologies transferable into the entrepreneurship education discipline? Can we provide classroom experiences that will be appropriate for future entrepreneurs? Are there methods we can use that will increase patterning cognitions for entrepreneurs? These are just a few questions that may provide the impetus for future research.

By examining the discipline of entrepreneurship education and its related pedagogies, it is hoped that this paper will have accomplished something in the way of providing a measure of clarity as to the issues that are relevant in the discipline and furthered the position that we must continue to refine our perspectives and research methodologies. The field is still emerging; however, it will no doubt, continue to strive to provide the necessary tools to students so that they have a firm foundation on which to build their new ventures.

**Table 1: Entrepreneurial Competencies from a Small Sample of Journal Articles**

| Competencies                           | Bird, 2002* | Thompson, 1999 | Santi, 1994** | Fiet, 2000 | Hisrich, 1992 | Hood et al, 1993 | Nieuwenhuizen et al, 2002 | Vesper et al, 1988 | Ronstadt, 1985 |
|--|-------------|----------------|---------------|------------|---------------|------------------|---------------------------|--------------------|----------------|
| Achievement/task motivation            | X           | X              |               |            |               |                  | X                         |                    |                |
| Change-oriented                        |             |                |               |            | X             |                  |                           |                    |                |
| Create & utilize networks              | X           | X              |               |            |               |                  |                           |                    | X              |
| Create capital                         |             | X              |               |            |               |                  |                           |                    |                |
| Creativity/Idea generation             | X           | X              |               | X          | X             | X                | X                         | X                  | X              |
| Decision making/evaluation             |             |                |               |            | X             | X                |                           |                    | X              |
| Design business organization           | X           |                |               |            |               |                  |                           |                    |                |
| Design products or services            | X           | X              |               |            |               |                  |                           |                    |                |
| Discipline/Drive                       | X           |                |               |            | X             |                  |                           |                    |                |
| Functional                             | X           |                |               |            | X             | X                | X                         | X                  |                |
| Interpersonal skills                   | X           | X              |               |            |               | X                | X                         |                    |                |
| Leadership                             | X           |                | X             | X          |               |                  |                           |                    |                |
| Listening                              |             |                |               |            |               |                  |                           | X                  |                |
| Manage growth                          |             |                |               |            |               | X                |                           |                    |                |
| Manage project                         |             |                | X             |            |               |                  |                           |                    |                |
| Manage risk                            |             | X              |               | X          | X             |                  | X                         |                    |                |
| Maneuver in industry                   | X           |                |               |            |               |                  | X                         |                    |                |
| Monitor the work of others             | X           |                |               |            |               |                  |                           |                    |                |
| Motivate org. members                  | X           |                |               |            |               |                  |                           |                    |                |
| Need for control of financial outcomes | X           |                |               |            |               |                  | X                         |                    |                |
| Negotiation                            |             |                |               |            | X             |                  |                           | X                  | X              |
| Opportunity recognition                |             | X              | X             |            |               | X                |                           | X                  | X              |
| Oral communication                     | X           |                |               |            |               | X                |                           | X                  |                |
| Reality Testing                        |             |                |               |            |               |                  |                           |                    | X              |
| Resource finding/financing             |             | X              |               | X          |               |                  |                           |                    |                |
| Planning, comprehensive                | X           |                |               |            |               | X                |                           |                    | X              |
| Plan strategy                          |             |                | X             | X          |               |                  | X                         |                    | X              |
| Technology                             |             |                |               |            |               |                  |                           | X                  |                |
| Tolerance for ambiguity                | X           |                |               |            | X             |                  |                           |                    | X              |
| Vision                                 |             |                |               |            | X             |                  |                           |                    |                |
| Writing                                |             |                |               |            |               |                  |                           | X                  |                |
| Ethics                                 |             |                |               |            |               | X                |                           |                    | X              |

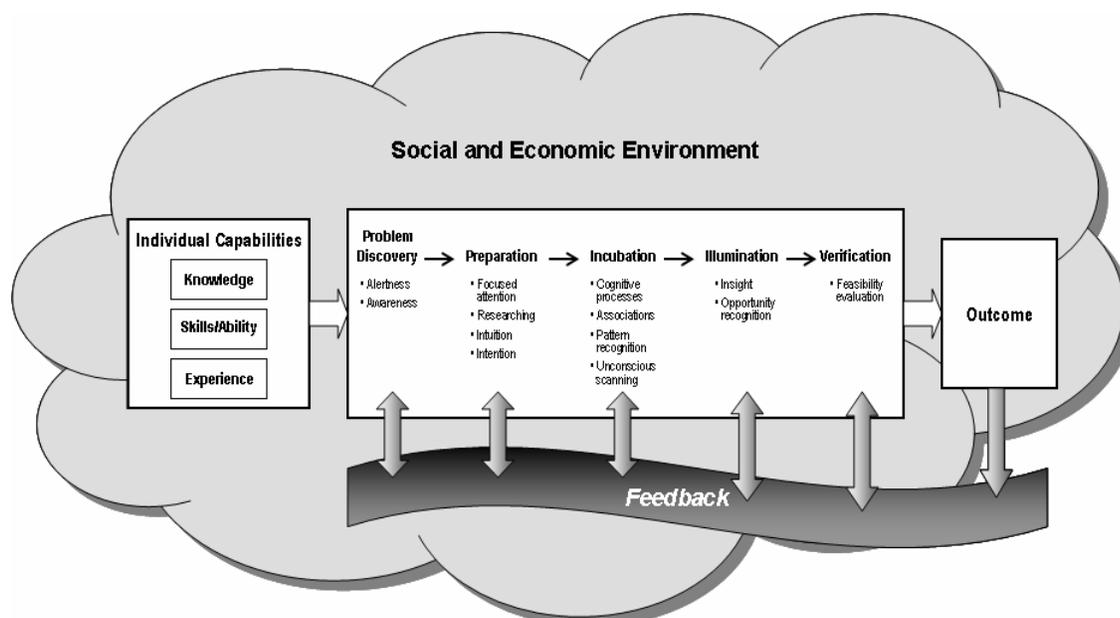

\*Success competencies with empirical support. Based on Working List of Entrepreneurial Competencies, Bird, 1995

\*\*As cited in Fayolle, 1998

Note: Hisrich lists three primary categories: technical, business management, and personal entrepreneurial skills

Note: Names of competencies may not match exactly those named in papers.

## **Abstract**

Building on previous studies, this paper examines the factors influencing the globalization of a particular group of SMEs - Canadian agricultural equipment manufacturers. From a population of 240 firms identified, we received 81 useable responses to our questionnaire. Data from the responses were analyzed using the PLS-graph program.

Two sets of data were considered – the entire sample, and a sub sample consisting of globally oriented firms. Findings indicate a strong direct impact of internal factors such as manager's international experience (30%, 20%, respectively on the samples above), firm's size (70%, 42%), and distinctiveness (0%, 37%) on the total variation explained in globalization. In addition to their direct influences, size and manager's experience have also an indirect and significant influence through distinctiveness.

The direct influence of external factors on SME globalization are moderate for standardization and uncertainty. Competitive pressures have also a moderate indirect influence (through standardization and learning).

The influence of strategic actions is less than moderate. Only scanning has an indirect and significant influence through distinctiveness and a moderate influence through learning. We think that the moderate influence of strategic actions could be related more to methodological problems than to the constructs themselves.

Globalization has a significant influence on the variance explained in profitability (30%, 36%). However, the model explained only around 10% of profit variation. The paper calls for further research on constructs of the model using adapted indicators with more relevance for SMEs.

# **THE RATIO DEPENDENCE PROBLEM IN FINANCIAL RATIO ANALYSIS FOR SMALL FIRMS: AN AUSTRALIAN PERSPECTIVE**

## **ABSTRACT**

Ratios determined from their financial records are often used to measure and monitor the performance of small firms. Understanding the nature of these ratios and possible problems in their computation and interpretation is a critical issue in the small firm domain. For example, the comparability of research studies demands a certain degree of constancy in variable definition and the interpretation of results. Also, developing assistance possibilities through public policy initiatives or advisory practice requires access to accurate and comparable sources of information.

Studies using factor analysis to select ratios from multi-business data bases have found that the number of factors may differ between data sets and that long-term stability may be questionable. Such differences give rise to the research question analysed in this paper – are the most commonly used predetermined ratios used in research and practice environments an independent set of ratios with respect to the data from which they are determined?

Factor analysis of the financial records of 3,986 Australian firms reduced an initial cohort of fifty-four ratios into eighteen independent factors. The null hypothesis that each of the six principal ratios most frequently used in research and in practice is an independent representative of one and only one factor is rejected. These results reinforce the need in studies of small firms to use factor analysis or other statistical approaches to determine independent factors rather than relying on a universal and predetermined set of ratios.

## INTRODUCTION

### SME Performance Categories

Small and medium enterprises (SMEs) are often placed into performance categories to assist analysis and understanding of separate firms and of aggregations of such firms. SMEs that grow, for example, is a category of SMEs associated with positive outcomes. These include: the creation of the major proportion of net new jobs in economies (Bridge, O'Neill and Cromie, 1998); contribution to innovative outputs (Holmes, Hutchinson, Forsaith, Gibson and McMahon, 2003); and, attractiveness to suppliers of funding because of prospects for financial returns as well as a "feeling of success through association" (Bridge *et al.*, 1998, p.163). On the other hand when a business ceases, due to bankruptcy for example, there are costs to the economy and costs to the firm that can bear disproportionately heavily on the SME owner (Robertson and Tress, 1985). Hence, SMEs that cease is another often used performance based category.

Where business assistance resources are limited, which is often the case, an appropriate way to maximise results is to apply those resources where they are most effective. Thus, when SME assistance (through, for example, public policy initiatives or consultancy based advisory practices) is focused on "what should be done and for whom?" (Larson and Clute, 1979, p.35), it is an important first step to be able to identify firms as 'belonging' to a particular performance category. For the growth firm, appropriate assistance may be in the form of "removing or easing impediments affecting development" (National Investment Council, 1995, p.15). For a firm with declining performance, appropriate assistance may be more in the form of managerial advice, resulting in corrective action and problem aversion (Robertson and Tress, 1985).

Financial information is generally important in many aspects of these processes. Identification of the performance category into which firms can be placed often relies on analysis of the financial characteristics of SMEs. Financial information is likely to be used to compare the performance of a firm with the average performance of a group of similar firms (e.g. industry groups). One approach to measuring and monitoring financial performance, especially in a comparative process, is the use of financial ratio analysis.

### Ratio selection

Financial ratios express relationships among items taken from financial statements. The traditional use of financial ratios has been as a measure of the liquidity, performance and profitability of a firm and thereby as a monitor of the efficiency and effectiveness of management (Thomas and Evanson, 1987). The ratio of current assets to current liabilities, for example, provides information about a company's ability to pay its current debts with existing current assets. Monitoring this ratio over time determines if this ability is increasing, declining, or is relatively stable. This ratio, known as the *current ratio*, also provides a measure that may be compared with a benchmark (e.g. the industry average of *current ratios*). The expectation is that managers use this information to improve the efficiency and profitability of their operation. Associated with this expectation is the implicit assumption that information from ratio analysis, especially trend analysis, enables management to foresee and possibly avoid business problems.

A common research focus relying on ratio analysis is the identification of discernible differences between the financial ratios of corporations that fail and corporations that do not fail. Beaver (1966) and Altman (1968) pioneered this approach and subsequently extensive work has been done in developing multivariate statistical models, which predict enterprise failure. Much of this work, however, has been developed using data from large firms, partly because an important ratio in Altman's model relies on data for the 'Market Value of Equity', which is not available for small firms. Edmister (1972) was one of the first to develop a failure prediction model specifically for small business in the USA. This was followed by studies in other countries such as those by Castagna and Matolsky (1981) in Australia and Taffler (1984) in the UK.

There has also been considerable debate in the traditional literature as to which ratios are most useful, and in particular, for assessing the likelihood of failure (Barnes, 1987). Ratio selection is a contentious matter because information overlaps individual ratios. On the one hand if all ratios were used the decision model would contain repetitive-redundant data, while on the other hand if only fully independent ratios were included the information content of the semi-independent ratios would be lost. The identification of those ratios, which contain complete information about a firm and also minimize duplication, "cannot be achieved purely by logic" (Barnes, 1987, p.456); in fact it is largely an empirical matter in which correlational independence is used as a statistical criterion.

Using data obtained from large firms, Gentry, Newbold and Whitford (1987) combined cash flow variables with financial ratios finding elements of both to hold predictive ability. With regard to financial ratios the study found that the ratios net income/total assets (NI/TA), total debt/total assets (TD/TA) and cash plus marketable securities/current liabilities (C/CL) were significant determinants of a firm's pending failure. A more recent study by Huyghebaert, Gaeremynck, Roodhooft and Van de Gucht (2000), using data from small to medium start-up firms in Belgium, obtained a similar result to that reported by Gentry *et al.* (1987). Huyghebaert *et al.* (2000) used the same ratios selected by Gentry *et al.* (1987) on the basis that Dimitras, Zanakis and Zopoundis (1996), in a review of business failure models over 12 different countries, had confirmed that those ratios are the "ones that are still most frequently used" (p.631). The seven most frequently used ratios identified in these studies were: net income/total assets (NI/TA), EBIT/total assets (EBIT/TA), total debt/total assets (TD/TA), cash flow/total debt (CF/TD), net working capital/total assets (WC/TA), current assets/current liabilities (CA/CL), and cash plus marketable securities/current liabilities (C/CL).

Huyghebaert *et al.* (2000), however, found multicollinearity problems with the Gentry *et al.* (1987) set of ratios. They found high correlations between the variables NI/TA, EBIT/TA and TD/TA, and between CA/CL and C/CL. Thus, the question is raised as to the wisdom of using a predetermined set of ratios on two grounds: Firstly, are they an independent set of ratios with respect to the data on which they are to be used? Secondly, is the scope of the set of ratios sufficient to capture the required information from the data? As previously indicated this is largely an empirical matter in which correlational independence is used as a statistical criterion. Correlational independence can be achieved by factor analysis (Dimitras *et al.*, 1996).

Ezzamel, Brodie and Mar-Molinero (1987), have recommended the more careful approach to ratio selection of seeking to re-identify the nature and magnitude of factor patterns for different

periods and for different countries. This study follows the suggestion by Ezzamel *et al.* (1987) and uses factor analysis to ‘re-identify’ the nature and magnitude of factors in Australian data in order to establish if the most used ratios as recognised by Dimitras *et al.* (1996) are the most suitable for a similar study to the one conducted by Gentry *et al.* (1987).

This decision to use factor analysis is supported by the following three arguments by Dimitras *et al.* (1996):

- The reduction or elimination of multicollinearity can be achieved by using factor analysis, an approach overlooked by many authors.
- If factor analysis is not used then it is still not clear which ratios ‘should’ be selected. For example, common ratios such as *Total Debt/Total Assets* and *Net Income/Total Assets* were reported by Dimitras *et al.* (1996), to be used widely in the United States but were not used at all in the UK studies in which they were interested (journal articles containing models pertaining to industrial and retail application). Thus, comparability would be an inherent problem whichever ratios were selected.
- The variable set should be constructed on the basis of (a) minimizing the cost of data collection and (b) maximizing the model applicability.

As indicated above, a number of studies using factor analysis to select ratios from multi-business data bases have found that the number of factors may differ between data sets and that long-term stability may be questionable. Such differences give rise to the research question analysed in this paper – are the most commonly used predetermined ratios used in research and practice environments an independent set of ratios with respect to the data from which they are determined?

## ANALYSIS

### Data

The data employed in the study was drawn from the Business Longitudinal Survey (BLS), conducted by the Australian Bureau of Statistics (ABS) on behalf of the Australian Federal Government (ABS, 1999), and released for independent analysis. This database contains data on business units employing fewer than 200 persons, which broadly represents SMEs (small and medium enterprises) in the Australian context. Data for 3,986 firms was used in the analysis.

Data collection in the BLS was achieved by the ABS through self-administered, structured questionnaires containing essentially closed questions. The questionnaires were piloted prior to their first use, and were then progressively refined in the light of experience after each collection. Various imputation techniques, including matching with other data files available to the ABS, were employed to deal with any missing data. The information collected in the BLS was sought under the authority of the *Census and Statistics Act 1905*. Thus, the Australian Statistician could legally enforce appropriate response to the mailed questionnaires. Consequently, response rates were very high by conventional research standards - typically exceeding 90 per cent.

The ABS Business Register was used as the population frame for the survey, with approximately 13,000 business units being selected for inclusion in the 1994-95 mailing of questionnaires. Approximately 6,400 business units were surveyed in each of 1995-96, 1996-97 and 1997-98 (a sub-sample of continuing businesses together with new business units added). Restricted industrial classification detail, no geographical indicators, presentation of enterprise age in ranges, and omission of certain data items obtained in the BLS all help to maintain the confidentiality of unit records. Furthermore, all financial variables have been subject to perturbation - a process in which values are slightly varied to provide further confidentiality protection.

As previously argued, the identification of ratios that contain complete information about a firm and also minimize duplication is largely an empirical matter in which correlation independence is used as a statistical criterion. Thus, this study uses factor analysis to 're-identify' the nature and magnitude of factors in Australian data related to small firms in order to establish if the most used ratios as recognised by Dimitras *et al.*, (1996) are the most suitable for a similar study to those conducted by Gentry *et al.* (1987) or Huyghebaert *et al.* (2000).

The set of financial ratios before factor analysis was applied is shown in Table 1. This set of ratios includes, where possible, those reported by Dimitras *et al.* (1996) in a review of business failure research. It also includes, where possible, the ratios used by both Gentry *et al.* (1987) and Huyghebaert *et al.* (2000). Finally it has been extended to include the ratios listed in the introductory accounting text by Atrill, McLaney and Harvey (2000) and by the addition of a ratio relating to superannuation.

Insert Table 1 about here  
-----

The ratios not included in the list are those where the CURF data imposes constraints on ratio calculation. Those ratios referring directly to Debtors and/or Cash and have been eliminated since Current Assets is shown only as a total amount on the CURF and does not disclose the component parts. Specifically, the value of the current asset items *cash* and *marketable securities* could not be determined. Therefore, the ratio C/CL, one of the seven ratios recognised by Dimitras *et al.* (1996) as the 'most used' could not be included in this present study.

Set in terms of the null form, the hypothesis tested was:

The CURF financial data factors into at least six factors in which the six ratios - *net income/total assets (NI/TA)*, *earnings before interest and tax/total assets (EBIT/TA)*, *total debt/total assets (TB/TA)*, *cash flow/total debt (CF/TD)*, *net working capital/total assets (WC/TA)*, and *current assets/current liabilities (CA/CL)* - are each an independent representative of one and only one factor.

## Results

Factor analysis reduced the data into eighteen independent factors (Table 2). Of the six ratios listed in the null hypothesis above (shaded in Table 2), CA/CL and CF/TD belong to the same factor (Factor 1), EBIT/TA and NI/TA belong to the same factor (Factor 3) and, WC/TA and TD/TA belong to the same factor (Factor 4). Thus the null hypothesis that each of the six principle ratios is an independent representative of one and only one factor is rejected.

## Discussion

The exploratory nature of this study was deemed necessary because of the nature of the BLS data file: the data file is large; it covers a broad cross-section of Australian SMEs; and the confidentiality requirements have necessitated the perturbation of financial figures.

It would appear from the results that factor analysis is a suitable method for discovering independent factors from which independent variables may be selected. For example, combinations of ratios used in previous studies were found to correlate highly in this study posing a possible collinearity problem.

It should be noted that the Gentry *et al.* (1987) study did find that NI/TA, TD/TA and C/CL were significant determinants of a firm's pending failure. The factor analysis in this study found that NI/TA and TD/TA belong to different factors. (C/CL has been discussed above in relation to data being unavailable on the CURF.) This prompts a replication of the Gentry *et al.* (1987), study using the results of this factor analysis, together with cash flow components, to further investigate whether small firm financial determinants are similar to those of large firms.

Further, the rather large number of independent factors found in this analysis tends to suggest that other studies should be undertaken to reveal other information contained in the BLS data. For example, the data could be divided into the performance categories mentioned in the introduction to this study, SMEs that grow and SMEs cease, and then analysed for category determinants. The results of such studies may help in the determination of efficient and effective distribution of scarce business assistance resources.

## CONCLUSION

This study employed factor analysis to explore the CURF data with the view to test the null hypothesis that the six ratios - NI/TA, EBIT/TA, TD/TA, CF/TD, WC/TA, CA/CL - are each an independent representative of one and only one factor. The results have rejected the null hypothesis. Thus it would appear that factor analysis might be a more suitable method for discovering independent factors than is the use of a predetermined set of ratios.

The approach to this study, in terms of factor analysis, has been vindicated by the finding of multicollinearity between ratios used in those previous studies and that other factors were found that were not used in those studies.

Further research is needed to show the relevance of individual factors for particular research questions. For example, which factors, if any, help determine the financial characteristics of small firms that, in the future, are most likely to grow?

| IE/S         | TD/TA        |               |                                |
| IE/TD        | Wages/Sales  |               |                                |
| Inv/COGS     | WC/TA        |               |                                |
| Inv/QA       | WC/(NI + D)  |               |                                |
| Inv/WC       | WC/NW        |               |                                |
| Inv/S        | WC/S         |               |                                |
| LTD/(LTD+NW) | WC/TD        |               |                                |

The set of financial ratios before the application of factor analysis includes, where possible, those ratios reported by Dimitras *et al.* (1996) in a review of business failure research. It also includes, where possible, the ratios used in the comparative studies by Gentry *et al.* (1987) and Huyghebaert *et al.* (2000). Finally it has been extended to include the ratios listed in the introductory accounting text by Atrill *et al.* (2000), and by the addition of a ratio relating to superannuation. Ratios not in the set include those where the CURF data imposes constraints on ratio calculation. For example, ratios referring directly to Debtors and/or Cash are not included because those items are not shown separately on the CURF.

## ABSTRACT

India is a developing country. Forty four per cent population of this country has a per capita income of even less than US\$1 per day. There are twenty nine states in India of which Chhattisgarh is a newly formed backward state. The economy of this state is dependent mainly on the abundantly available minerals, agriculture and a few major industries like the 'Steel Giant Four Million Ton Bhilai Steel Plant', an aluminum plant and a thermal power plant.

In addition, there are a few hundred small businesses including fabrication units, foundries, construction units, ceramics & tiles units, tobacco units, solvent extraction plants, rice mills, fruit preservation units, steel re-rollers etc. Very few owners of these units possess the necessary professional qualifications in engineering, finance or business administration. The situation is worse in the case of workers. They possess little or no technical education. Most of them have acquired their skills on- the- job, affecting the degree of productivity accordingly.

A study has been conducted on these small businesses and it has been concluded that the situation can substantially improve with –

Increased awareness of owners

Training & development of workers thru' :

On the job training

In house training

Sponsoring for outside training, &

Job Rotation

Better Wage Administration with Productivity based Incentive Schemes

Improved working conditions

Opening Additional Technical Institutes

The study recognizes the fact that the resources available with the small businesses in Chhattisgarh state are limited and therefore lays heavy emphasis on collective efforts and support from other big industries like **Bhilai Steel Plant of Steel Authority of India Limited** which is a socially responsible corporate citizen and already supports 170 ancillary industries in the region. The authors are reasonably convinced that this study would be useful for other developing nations too.

## INTRODUCTION

In the last decade the industrial scenario in India has undergone a considerable change. With new market economy resulting from liberalization, there is an influx of many companies as well as products at highly competitive prices and diverse functions. The local manufacturers have to face competition from indigenous as well as foreign products available at cheaper rates. Under the circumstances if an organization is not geared up to meet the challenges of this changing situation it will be thrown out of the business scene in no time. To meet the competition, a company has to be equipped with the necessary technical know-how so that it can make

optimum use of its resources to make a superior product quality-wise yet at a competitive price. This is possible only if the manufacturers can improve their productivity i.e. the no. of goods produced per unit of a resource and this can be achieved only through the best use of all their resources including the manpower.

## **INDIA : BASIC FACTS (1)**

India occupies a strategic position in Asia, looking across the seas to Arabia and Africa on the west and to Burma, Malaysia and the Indonesian Archipelago to the east. Geographically, the Himalayan ranges keep India apart from the rest of Asia. Spread in 3287 thousand square kilometers, the country has a population of more than 1000 million people, thus putting the population density to more than 275 people per square kilometer. The per capita income of this country is only about US\$300 per annum amounting to a pitiable US\$0.83 per day with 44.2 % population actually earning less than one US Dollar per day. India is basically an agricultural country with about 70 % population living in villages. After its independence in 1947 from the British rule, India has tried to take a leap towards industrial revolution but is still categorized as a developing nation belonging to the third world. Obviously, the economic growth has neither been at the required pace nor has brought affluence to the masses.

India is divided into 29 states on linguistic basis. The division of the country into states has been helpful in regional development. The state of Chhattisgarh, which is the subject of the current study, was recently carved out of a larger state called the Madhya Pradesh mainly because of the unmanageability of the vast forest areas and distant population in the erstwhile Madhya Pradesh.

## **CHHATTISGARH STATE (2)**

As stated earlier, Chhattisgarh is one of the twenty nine States of India having come into existence only on 1<sup>st</sup> November 2000. Spread over 135,133 square kilometers, the state occupies 4.14 % land area of this country and 20 million people, which is only 2.02 % of the population of India, live in Chhattisgarh. Eighty three percent of the population lives in 19,658 villages while the remaining seventeen percent lives in six big cities and seventy five other towns. The male- female ratio in the population is almost equal. The state's economy is basically dependent on agriculture. Forty five percent land is cultivated and although there are 39 big and small rivers yet only 12% land is irrigated. There are dense forests in about 45% land area of the state. Therefore, the modern civilization has not reached the population living in the distant forest areas, away from railway line.

The state is rich in minerals which include Coal, Iron Ore, Lime Stone, Dolomite, Bauxite etc. but the state is industrially backward. There are only three major industries namely the 'four million ton public sector steel plant' at Bhilai, a 2125 MW public sector thermal power plant and an Aluminium Plant at Korba. There are a few cement factories as well in the private sector. While another steel plant is coming up in the private sector, a 500 MW Power Plant has also been planned in collaboration with Gujrat State.

The *other industries are all in small sector* with many of them registered as 'small scale industries', many as 'cottage industries' and yet many as 'ancillary industries to Bhilai Steel Plant'. The industrial growth in the state has been dependent on agricultural and forest products as also on abundant Iron Ore. *The huge quantity of semi finished steel products and steel scrap generated from Bhilai Steel Plant has also led to the establishment of a number of steel re-rolling mills.*

Having started its production in 1959, **Bhilai Steel Plant, the flagship plant of Steel Authority of India Limited**, contributes very substantially to the economic development of Chhattisgarh state. Not only the Plant provides employment to about 37000 strong workforce but also has paid US\$ 570 million to the state exchequer so far by way of payment of sales tax, excise duty, power charges, water charges, property tax etc. The Plant also supports 170 ancillary industries in three adjoining districts and places orders on them to the tune of about US\$ 20 million every year. *Being a socially responsible corporate citizen, Bhilai Steel Plant is willing to contribute further to the welfare of small business units in this region.*

The fact still remains that Chhattisgarh is an industrially backward state. Except for those workmen employed in large industries, the remaining are mostly unskilled. Whatever little skills have they acquired, they have been mostly 'on-the-job'. This study is, therefore, an attempt to establish the existing skill pattern of employees in small business in Chhattisgarh state, the impact of skills on productivity and suggestions for improving the situation. *Acknowledging the fact that the small industries sector in Chhattisgarh can benefit from the help from Bhilai Steel Plant, suggestions for the same have also been incorporated.*

The state is divided into 16 districts for administrative convenience which are almost equal in respect of industrial development except a few namely the Durg district which is considered highly developed because of the Bhilai Steel Plant, the Raipur district being the capital of the state and the Bastar region which is undeveloped because of its dense forests and tribal population.

We would now present a detailed study in one of the sample districts of the state which is by-and-large a representative district of Chhattisgarh.

### **THE LOCALE : RAJNANDGAON (3)**

The district Rajnandgaon came into existence on 26<sup>th</sup> Jan. 1973, by way of division of district Durg. The district Rajnandgaon is in the south eastern part of the newly formed state of Chhattisgarh. The district headquarter Rajnandgaon is on the Bombay – Howrah line of South Eastern Railways. The National Highway Number 6 (The Great Eastern Road) also passes through the town of Rajnandgaon. The nearest airport to the district is at Mana (Raipur), about 80 kms away.

**General Details :** Total area - 6396.28 sq.k.m. Forest area – 2987.14 sq. k.m. Climate – tropical Average rainfall – 1274 m.m. Main crop - Paddy Population : 107890 as per census 2001. Literacy percentage – 48.39%. Minerals – limestone, china clay, quartzite, granite, white clay.

It is a developing city whose population is largely illiterate, poor and dependent upon agriculture as a means of living. Awareness towards education or technology is low and so is the economic standard of living. There are hardly any govt. technical educational institutions here. The people living in the city are mostly traders, who dominate the business scene from down the generations.

**The Industrial Scenario :** There are 119 medium, small & tiny industries in Rajnandgaon district (Refer **TABLE:I** at the end) and industrially it is categorized as 'B' – 'backward' by the Chhattisgarh Government. The development of industries here has been quite reluctant, with only a few local private business firms taking the initiative for industrial growth. The only Government textile industry, BNC Mills closed down a few years back after suffering from a long period of industrial sickness. Although there are a few public sector undertakings in the neighboring cities of Bhilai and Korba, industrialization of this primarily agricultural area has

been painfully slow. Barring a few, almost all industries are small scale units, with capital investment around US\$ 50,000 only. With the exception of a few fabricating units most of these are agriculture based like solvent extraction plants, rice and pulses mills and tobacco processing units. The growth of these industries can be attributed to the easy availability of raw material like iron & steel and agricultural products needed for these industries.

#### **AVERAGE WORKER PROFILE. (4)**

Before casting a glance on workers' profile, it would be prudent to have a look at the qualifications of the owners of the small business units in question. Except a few, most of the entrepreneurs do not have any professional qualification like an engineering degree or an MBA. They are simply graduates or post graduates who have inherited their family occupations. The individuals owning the agricultural and tobacco processing units mostly belong to this category. Some of the owners of these units are not even graduates. Only some manufacturers of fabricated items have a technical degree or diploma. Not a single MBA was found in the entire industrial sector of Rajnandgaon, the reason being that if at all there are MBAs in Rajnandgaon, they would not believe in wasting their qualifications in a small developing city, rather they would choose to move on to higher paying jobs in more developed cities

**Workmen:** Most of the workers learn on the job. The skilled workers generally belong to the guild of artisans who have inherited a particular craft traditionally. Although labour comes cheap here as compared to more developed areas, their lack of skills neutralizes any advantage that could have been gained from this fact. Another factor that adds to labour related problems is illiteracy which leads to a very low degree of motivation and a disinclination to learn. The employers also face problems of low turnout of workers during reaping seasons as most of the workers belong to farming families and work as seasonal workers.

There is one women polytechnic for diploma courses and only one industrial training institute in the district providing certificate courses in various trades like welding, fitting, rigging, carpentry, smithy etc. But the pass outs from these institute are attracted by bigger industries like the Bhilai Steel Plant and the small business units are left at the mercy of untrained labour mostly.

Thus, although labour is cheap here, owing to lack of technical training schools, there is a scarcity of trained industrial workers. Consequently, the industries have to be content with semiskilled or unskilled workers who can perfect a job through trial and error or experience. The limited funds available to the industry owners do not permit them to spend on training or counseling of employees even if they are aware that poor skills reflect adversely on their performance

Skill wise distribution of the workmen is reflected in **TABLES: II & III** at the end.

#### **PRODUCTIVITY (4)**

The output per unit of resource known as productivity of these small scale units in Rajnandgaon is reflected in **TABLE:III**. *It can be clearly seen that higher the skills, higher the productivity.* The skills are limited due to lack of funds and supporting infrastructure. As discussed earlier, this tiny part of Chhattisgarh is a developing city both economically and industrially. Industrial development here, like any other part of the country, can be related to such factors such as availability of material, funds, skills, power, market etc. Being a backward area, funds, skills and infrastructure are scarce, resulting in low productivity. In some units utilization of capacity is not even 40%. Further more, there are no research or development units that offer new technologies for improved productivity. Foreign collaborations are unheard of. Under the

circumstances it is hardly surprising that the products are manufactured through outdated technologies and hence lack quality.

**Very** few financial institutions are willing to make an investment here for industrial growth. Consequently the onus of monitoring the industrial growth lies on Government bodies like the Chhattisgarh State Industrial Development Corporation and Chhattisgarh Industries Consortium or a few enterprising individuals. With shortage of funds and absence of an infrastructure supporting industrial development, the performance of the existing industries is poor and they are in no position to compete with similar industries of developed areas. As a result they have to be content with the local market and low revenues only. The owners of these industries are more concerned about tackling the day to day problems related to survival rather than long term planning for improving their performance.

Obviously the manufacturers would like to operate more efficiently. Other factors remaining unchanged, a large amount of the company's funds are spent as salaries and wages. The manpower of the organization forms the substantial part of an organization's resources. If this resource is used to one's advantage, the benefits derived in the form of higher efficiency would be immense. Hence the manufacturers would like to use the available manpower more efficiently and improve the existing capacity.

**Future prospects** : Even with so many positive points on its side such as availability of raw material, cheap labor and transportation facility, the industrial growth in Rajnandgaon district has not been as fast as expected and on the whole it can be concluded that the prospects of industrial development are presently not very encouraging. *Only with the help of the big public sector industries in the region like the Bhilai Steel Plant, collective initiative of a few professionally qualified individuals for an overhauling program of the existing situation and through introduction of new supporting policies from the Govt. like providing subsidies on agricultural goods and change in taxation pattern it can be hoped that there will be a change for the better.* Financial institutions like the Industrial Development Bank of India, the Finance Corporation of India and other banking institutions have decreased their interest rates on midterm loans as well as cash credits and this may prove beneficial to the industries. There has also been a proposal for opening a Boys Polytechnic from the Govt. in the near future that may satisfy the manpower requirements of Diploma Engineers of this area and ascertain better productivity and quality and consequently a wider market.

Availability of funds is expected to inspire the manufacturers to pay more attention to training and development of skilled workers, the lack of which is probably the reason for its sustained growth. This coupled with the abundant supply of raw material is bound to result in increased productivity. *A study of this type that focuses on the influence of skills of workers on performance may provide the entrepreneurs a basis for taking concrete steps to improve skills as a means for improving performance.*

## SUGGESTIONS FOR IMPROVEMENT

### **Suggestions to improve Owners' Awareness**

The lack of technically/ managerially or financially qualified owners has made their overall awareness suffer to a large extent. They are ignorant about new processes or technologies that could be useful to them. Many of them are not even aware of the revised policies guiding the small industries sectors or the products reserved for Small Scale Industries. They have not heard of layout designing or value addition or product diversification.. No wonder the products are still manufactured through age old technology without any updating or change in utility or design.

Since the owners are long past the age of attending colleges and their limited time does not permit them to study further, it is suggested they be provided a minimum class room understanding on industrialization by the *big industries in the region like Bhilai Steel Plant*. This should be followed by these owners attending seminars and trade fairs that are arranged by CSIDC and other organizations to publicize new technologies and products. This should further be supplemented by hiring a consultant to suggest modernization of the existing units.

### **Suggestions for Training and Development of workers**

The limited financial resources of the industries based here do not permit the entrepreneurs to invest in training of the workers. As a result they manage somehow with unskilled and semiskilled workers expecting them to learn while working on the job. This costs them lower productivity in terms of high defectives and material wastage and poor quality. Recruitment of technically qualified workers means higher wages which they are unable to afford. Under the circumstances they have to be content with the poor performance of the industries. Moreover training the workers may entail hiring training personnel or arranging training workshops for them. This again would mean additional expenses for the owners.

Another factor that hinders training and development is the attitude of the workers as they do not show an inclination to learn as they have a deep rooted suspicion about the owners' intentions and they offer resistance to any new developmental process taking place in the organization. They do not hope to get any additional benefit from improved productivity and so they are not interested in learning more about their job.

Training and development of workers is the most important input for improving the skill pattern of the workers but as discussed earlier it is not an isolated process. Training and development can work only if all the employees are committed to achieve higher productivity through improved performance. This implies the change in the entire organizational culture and can be affected through the managements' efforts to inspire confidence in these changes that they are going to be beneficial to one and all. Only then can the workers be expected to cooperate with the management in getting trained.

The various methods of training that can be introduced in the Small Business Units without being extraordinarily expensive are described below.

**On the job training :** This is perhaps the most prevalent method already in use in the industries of Rajnandgaon district as it involves no additional costs. The workers learn while working on the job. But, this method is more suitable when the basics of the job are known to the workers. It aims at developing the skills of the workers to a higher level by polishing their existing skills through practice. The process improves the performance of an individual by adding to the accuracy in his work and reducing material wastage & defectives.

This type of training cannot work for very large periods for the same group of workers as improvement can take place only to certain level through this process.

**Apprenticeship:** It is recommended that the small industries of Rajnandgaon district may adopt this system because of its lower costs. Here a worker is recruited as an apprentice for an allowance under another experienced worker. He is supposed to learn from the skilled worker by observing him at work and attempting the job under the surveillance of his mentor. As he learns gradually more independence is given to him and constant supervision from his mentor is withdrawn. This training is suitable for entirely new jobs also.

**Job Rotation :** Job rotation is aimed at improving the skills of the workers by reducing the monotony of his work as also encouraging the workers to learn new skills. This is helpful in the development of the workmen through their deployment when there is high pressure on one job center. Also it helps in times of high absenteeism.

**Training workshops:** The existing skills of the workmen can also be improved by their exposure to training workshops in which invited outside faculty, their supervisors & other experienced workers demonstrate to them on how to perform a job efficiently without wasting resources. But such workshops are normally not preferred by the management because it means loss in terms of production time of the participating workers. If the instructors are hired from outside then it means paying them too. This kind of training is specially recommended for those industrial units which are ancillary units to a bigger industry and have to produce jobs as per the required process and design specifications. It is helpful in learning new technological developments where instructors from the suppliers of the new technology demonstrate on the working of a new tool or equipment and invite the workers to work on those lines in the workshop. *Training personnel from Bhilai Steel plant can be associated with such workshops in the region.*

**Sponsoring a candidate to a technical institution or to a parent industry for training:** Although it is one of the most expensive ways of skill development, yet it certainly is one of the most effective tools of training because of the inherent advantages of outside training. The biggest advantage is the better preparedness of the trainees in the new environment away from the routine work place. Such deputations may also be helpful when a new production venture is planned so that the worker becomes conversant with the production methods required for a new product. *Bhilai Steel Plant can be a good training ground for the workmen from small scale industries of the region.*

### **Better Wage Administration**

Most industries in Chhattisgarh make payments to the workers on daily or weekly basis. A daily rate of workers is fixed and deductions for absence are made while making payments. Very few industries offered incentives for better productivity. The pay scale is low as compared to the developed states. Some industries also employ the piece rate system and performance of these industries is better than those of the daily rate system. Most of the workers are temporary and other allowances are not provided to them. Very few industries offered a festival bonus to the workers .

*Productivity based incentive system of wage administration* can help to motivate the workers to produce more number of jobs. A standard number of jobs per day can be fixed after consulting analyzing each job. For each job produced above the standard number an incentive should be offered over and above the fixed rate of wage. Also cash rewards can be offered for the lowest absenteeism and lowest defectives and material wastage. These rewards will also act as incentives for the workers and they will be motivated to improve their skill pattern resulting in higher productivity.

## **The general atmosphere of the organization**

Most organizations have not brought in any changes regarding the organizational methods in functional areas. In this age of modernization where there is a revolutionary change in almost all the concepts of industrialization this complacency has brought about a careless attitude at every level of the organization. Since improvement of skill pattern involves not only training of the workers but also a change in their attitude, this type of a climate becomes a serious drawback in attempting anything for skill development. Improvement in skill pattern means a change in the organizational climate so as to make everyone in the unit aware of the true position of the unit, the change in policies to realize a growth and the plans for it. This needs an openness from the owners that invites involvement from the supervisors and workers.

**Suggestions to improve the organizational climate:** Annual reports containing statements about the performance of the unit in terms of turnover and profits made should be made available to all the employees of the unit. The report should also contain the annual planning of the unit that underlines its intentions of bringing in new developments such as expanding its market or introducing new technology. This will generate a confidence in the management's intentions as well as make the employees feel more responsible. Unless the goal is specified, the path for reaching there cannot be determined.

**Working conditions:** Working conditions in the small industries of a backward state play a very important role in the skill pattern of the workers. The survey of many industries revealed that the working conditions of the units were terrible especially in agro based industries i.e solvent extraction plants, tobacco processing units and fertilizer producing units. The workplaces did not have proper ventilation or lighting. Fumes and intoxicating agents polluted the atmosphere which was detrimental to health. Lack of lighting, space and air made the working conditions of the workers very uncomfortable and this reflected on their skills poorly. In many factories the workers were seen crouching in an uncomfortable position bending on their jobs in poorly lighted and humid environment. No wonder the workers were demotivated, and showed a half hearted attitude towards their work. In agricultural units, chaff covered the area to such an extent that it was difficult to breathe.

In fabrication and rolling mills noise pollution from the machines was too much for a normal person to bear. In many units workers were seen to work on welding machines without using masks and gloves. Often, work-in-process goods were seen lying on the floor which made movement difficult. This made the flow of material more time consuming than necessary. Owners although seemed very reluctant to accept this fact, they implied that their limited funds restricted them from investing in improving the working conditions of a unit.

**Suggestions for improving working conditions:** Since working place conditions contribute a lot in the state of productivity and skill pattern, care should be taken to improve them. A little investment and concern from the owners will go a long way in enhancing both productivity and skill pattern of the organization. The working environment can be made more hygienic by attending to small details like proper ventilation, installation of chimneys and keeping the workplace pollution free and well lighted and airy so that the worker feels more comfortable working. This will add to their efficiency. Safety appliances like gloves, shoes, masks and cotton wool should be provided to them so that injuries to the workers are prevented.

They should be provided better seating arrangement and the height of the work table should be such that one does not have to bend too low or strain oneself unnecessarily. Discomfort or cramped muscles will affect the performance. Wires spread over an area or objects littered on the floor restrict movements. Care should be taken to neatly stack the semi finished and finished

goods on one side and the wires should be laid on the walls near the machines. If attention is paid to these factors and the owners show a little more concern they will surely be rewarded in the form of improved performance.

### **Opening Of New Technical Institutes.**

There are only two technical institutes in the whole of Rajnandgaon district viz, a government women polytechnic (providing diploma in office management, electronics engineering, costume design and dress making) and one government industrial training institute (providing certificate programs in surveyor, instrumentation, mechanic, welder, electrician, fitter, plumber, cutting & tailoring). The students passing out from the polytechnic and the industrial training institute are firstly very little in number and secondly like to try for better jobs outside the district. It is, therefore, suggested that efforts by the industries owners should be made for opening more private technical institutes as well as for getting more government technical institutes opened in the district.

### **NEED FOR COLLECTIVE EFFORTS**

The owners of small business houses in Rajnandgaon district are not so well off that they would be able to take most of the above mentioned initiatives for improving the productivity of their units individually. It is therefore strongly recommended that these initiatives should be tried jointly by the owners particularly in the areas of organizing training workshops, sponsoring for outside training and getting technical institutes opened in the area.

### **ROLE OF BIG INDUSTRIES AROUND, PARTICULARLY THE BHILAI STEEL PLANT of STEEL AUTHORITY OF INDIA LTD**

There are a few big industries in the region including the all-powerful and self-sufficient Bhilai Steel Plant, the flagship plant of Steel Authority of India Limited, which is the largest Public Sector & ISO 9001:2000 certified Steel Plant of India producing more than four million tons of steel every year and employing about thirty seven thousand employees. The plant has been giving profits to the nation continuously for the last seventeen years and has earned during 2003-`04 the highest ever profit by any Indian steel plant so far. *It is one of the best acknowledged socially responsible corporate citizens which can be compared to any responsible society around the globe.* The Plant has spent colossal amounts of US\$ 31.48 millions, 41.35 millions & 44.12 millions on Social Amenities like township, education, medical, sports & cultural etc during the fiscals 2001-02, 02-03 & 03-04 respectively.

The Plant already supports 170 ancillary industries in the small scale sector in the districts of Rajnandgaon, Durg & Raipur. The Plant had placed about three thousand orders on these industries in 2003-`04 valuing about US\$ 20 millions. The Plant provides all necessary technical guidance to them including selection of product & raw material, preparation of project report, stage inspections etc. Therefore, it would be easy by the Plant to increase its area of operation a little in respect of the small scale businesses in the state and help their owners in acquiring necessary awareness on industrial development & its need in Chhattisgarh through programs at its Management Training Center, in providing institutional training to the workmen from these industries in its all-developed Training Institute, providing on the job training in a large number of jobs, providing necessary guidance to them on house keeping & safety and above all keeping their morale high by playing the role of their 'big brother' in a limited manner.

## INFERENCES

This study reveals the state of small scale industries in an industrially backward area with reference to its skills and productivity and has tried to show a relation between the two. It can be surmised that productivity is a function of the skill pattern and any change in the former has to be brought about by introducing a change in the latter. Changes in skill pattern can be brought about through the attitudes towards work, training and the general work environment. Only then will the skill pattern of the workers improve and result in higher productivity.

Industrially, Rajnandgaon is a representative district of Chhattisgarh with the exception of only two-three districts which are very well developed because of the presence of big public sector industries & their ancillaries. There are also a few districts in the tribal belt where even minimum industrialization has not reached. The findings of this study are, therefore, reasonably extendable to the entire state of Chhattisgarh.

To the best knowledge of the authors of this paper, no professional study clearly relating the skills of the existing workmen in small business units in Chhattisgarh state and their productivity has so far been made. In the absence of such a study, the employers cannot take any concrete steps. If a study is made available to the industrialists specifying the extent to which improvement in one parameter affects the other, they could certainly use the results of such a study to their benefit. This kind of a study will enable the owners to deploy their human resources more profitably. Also the results of the study will inspire the workers to perform better especially the ones working on piece-rate system. The paper should be helpful in human resource development in an industrially backward state of India which in turn would improve the performance of the industries based there enabling them to find a wider market for their goods and face the increasing competition even globally.

Analogically, this kind of a study should also be equally useful for other developing nations with similar circumstances.

### ENDNOTES

This Paper is basically based on an actual field research and relies heavily on the primary data collected during the study.

**DETERMINANTS OF REGIONAL VARIATIONS  
IN THE START-UP RATIO: EVIDENCE FROM JAPAN**

(reduced length version)

Abstract:

Since the 1990s, new firm formation rate in Japan has been quite low, even lower than the closure rate. Therefore, promotion of business start-ups is one of the most important policy issues. However, despite distinct regional variations in the start-up ratio, there exist few econometric studies on the determinants of these regional variations in Japan. Thus, this paper analyzes the regional determinants of the start-up ratio in the latter half of the 1990s using two datasets with different levels of regional segmentation. The explanatory variables represent demand, cost, human resource, financial, industry agglomeration and industrial structure, and other factors. The empirical results obtained using WLS and OLS analyses demonstrate that while all the above factors significantly affect the start-up ratio at the municipality level, some of these factors are not significant at a larger economic area level. In particular, we obtained evidence that human resource factors together with the average wage and average size of establishments are important determinants of the regional start-up ratio in both the samples. These results suggest that the accumulation of human resources is essential to vitalize regional economies through start-up activities.

## **1. Introduction**

Since the early 1990s, the new firm start-up rate has been lower than the closures rate in Japan. Several public-supported measures were taken in order to encourage start-up activities and to arrest this continuous decline in the numbers of firms; however, these have not achieved any success to date. Business start-ups make several contributions, which are critical not only from the macroeconomic viewpoint, but also for the regional economy. Therefore, in order to obtain policy implications, it is very important to explain the regional factors that impact the business start-up ratio.

Despite of remarkable regional differences in the start-up ratio, the factors affecting these differences have not yet been sufficiently explored in Japan. Instead, early studies have focused on macroeconomic or industrial factors, or the personal profiles of entrepreneurs (Yamawaki [1991], Odagiri and Honjo [1995], Genda *et al.* [1998]). Analysis of regional factors has commenced recently, and is based on prefecture-level data. However, we consider that prefectures in Japan are too large to facilitate an effective analysis of the regional variations. Therefore, the main purpose of this paper is to analyze the regional factors affecting the start-up ratio in the latter half of the 1990s using regional data from different levels, namely the municipality (cities, towns, and villages) and the economic area levels.

## **2. Previous Studies**

Previous studies on the factors affecting start-up activities have been carried out mainly in the U.S. and European countries. These studies can be classified into the following categories: i) analysis of industry factors, ii) analysis of regional factors, and iii) analysis of personal profiles of entrepreneurs. In this section, we review the results of these studies, focusing on the analysis of regional factors.

The analysis of regional determinants of the number or rate of business start-ups became popular in Western countries in the 1990s. Most studies divide the entire country into dozens or hundreds of regions and use pooled data from several time periods. Regional factors can be categorized into demand, cost, human resource, financial, industry agglomeration and structural factors, and other factors. We now present a brief discussion of these factors.

First, several studies indicate that demand factors, such as population growth, are the most direct determinants of the start-up ratio (Moyes and Westhead [1990], Audretsch and Fritsch [1994], Davidsson *et al.* [1994], Guesnier [1994], Keeble and Walker [1994], Reynolds *et al.* [1994], Reynolds *et al.* [1995], Small and Medium Enterprise Agency [2002], [2003], Armington and Acs [2002], Acs and Armington [2004]).

Second, the effects of regional cost disparities on the start-up ratio have been analyzed using labor costs and land prices or office rents. Several previous studies demonstrate that the regional wage level negatively affects the start-up ratio (Ashcroft *et al.* [1991], Gerlach and Wagner [1994], Santarelli and Piergiovanni [1995], Audretsch and Vivarelli [1996], Kobayashi [2004]). With regard to the land prices or office rents, previous studies observe both positive and negative impacts on the start-up ratio.

Third, with regard to human resource factors, several studies focus on the effect of the qualitative and quantitative composition of regional population and labor forces as well as the effect of the employment situation on the start-up ratio. With regard to the effects of the composition of population and labor forces, several studies have demonstrated that the proportion of highly skilled labor (Audretsch and Fritsch [1994], Fotopoulos and Spence [1999]), proportion of university graduates (Guesnier [1994], Armington and Acs [2002], Acs and Armington [2004]), and proportion of the workforce in professional and administrative occupations (Guesnier [1994], Hart and Gudgin [1994], Keeble and Walker [1994]) have a positive impact on the start-up ratio.

With regard to the employment situation, there are conflicting views on the effect of the unemployment rate on the start-up ratio. On the one hand, it is considered that a high unemployment ratio increases the start-up ratio as several unemployed persons set up businesses in order to secure employment for themselves (Evans and Leighton [1990], Storey [1991], Small and Medium Enterprise Agency [2002]). On the other hand, several studies show that a high unemployment ratio reflects a sluggish regional economic situation and thus hampers business start-ups (Carree *et al.* [2002], Reynolds *et al.* [1995], Nerlinger [1998], Steil [1999]).

Fourth, with regard to the financial factors, several studies indicate that difficulties in financing start-ups have a high negative impact on the start-up ratio. A remarkable aspect in this regard is the relationship between the start-up ratio and the householder ratio, since the ownership of housing can act as a collateral and a safety net for the founders. However, the empirical results carried out in the Western countries and Japan differ in this aspect (Moyes and Westhead [1990], Ashcroft *et al.* [1991], Guesnier [1994], Kobayashi [2004]).

Fifth, with regard to industry agglomeration and industry structure, several studies indicate that the start-up ratio is positively affected by agglomeration (Papke [1991], Audretsch and Fritsch [1994], Davidsson *et al.* [1994], Guesnier [1994], Keeble and Walker [1994], Reynolds *et al.* [1994], Armington and Acs [2002], Small and Medium Enterprise Agency [2002], Acs and Armington [2004], Kobayashi [2004]). With regard to the influence of industry structure on business start-ups, previous studies concur that a smaller proportion of the manufacturing sector has a positive effect on the start-up ratio (Evans and Leighton [1989], Reynolds *et al.* [1995], Egelin *et al.* [1997]).

Sixth, with regard to the other factors that affect the regional start-up ratio, previous studies focus on the average business size, traffic access, and the role of the public sector. Several studies report that the smaller the average business size or the higher the share of small businesses, the higher is the start-up ratio (Moyes and Westhead [1990],

Ashcroft *et al.* [1991], Fritsch [1992], Audretsch and Fritsch [1994], Gerlach and Wagner [1994], Guesnier [1994], Hart and Gudgin [1994], Keeble and Walker [1994], Reynolds [1994], Santarelli and Piergiovanni [1995], Audretsch and Vivarelli [1996], Egelin *et al.* [1997], Nerlinger [1998], Fotopoulos and Spence [1999], Steil [1999], Armington and Acs [2002], Acs and Armington [2004]).

Only German studies have investigated the impact of traffic access, reporting that the start-up ratio, particularly in the high-tech sector, is higher in regions that have convenient access to express trains (ICE) or highways (Berger and Nerlinger [1997], Felder *et al.* [1997], Nerlinger [1998], Steil [1999]).

Previous studies on the role of the public sector have focused on tax rates, whereas Papke (1991) and Reynolds (1994) examined the effect of public expenditure on the start-up ratio and observed a positive and negative effect, respectively.

Almost all the studies reviewed in this section pertain to Western countries. Few empirical studies have been carried out on the regional factors affecting the start-up ratio in Japan. In addition, while the U.S. and German studies divide the entire country into hundreds of regions, no detailed studies have been carried out in Japan that use data of areas smaller than the prefectures. Therefore, it is difficult to derive any implications regarding the methods to promote business start-ups at the regional level in Japan. In order to overcome this difficulty, we analyze the regional determinants of the start-up ratio on the basis of previous studies, using regional data of units smaller than the prefectures, namely, the municipality and economic area.

### **3. Analytical Models, Hypotheses, and Data**

#### **3-1. Models, Variables, and Hypotheses**

In this paper, we employ the weighted least square (WLS) and the ordinary least square (OLS) analyses, using a linear multiple regression model with the start-up ratio as the dependent variable. For the same start-up ratio, a highly urbanized region records hundreds or thousands of times more start-ups than a rural region does. From the viewpoint of policy implications, regions with a large number of new start-ups should be assigned a higher weight. Therefore, we consider that the WLS analysis is more preferable to the OLS model in the context of this paper. We utilize the initial number of establishments (those in 1996) as the weight for the WLS analysis.

On the basis of previous literature considered in Section 2, we propose the basic model as follows:

Start-up ratio = f (demand factors, cost factors, human resource factors, financial factors, factors of industry agglomeration and industry structure, other factors)

Table 1 about here

Table 1 lists the definitions of the variables. The growth rate of the total number of private establishments during 1996-99 is the dependent variable. This variable is calculated by dividing the number of start-ups during this period by the total number of establishments in 1996.

As a variable of the demand factors, we utilize the population growth rate (GRPOP), which is the most widely employed measure in previous studies. We utilize the data of the preceding period as a proxy for the expected demand growth.

H 1: The start-up ratio is higher in regions where a higher demand growth is expected (GRPOP +).

The primary cost factors for a business start-up are capital costs, labor costs, and rents for land and office spaces. By classifying capital costs as a financial factor, we focus on labor costs along with various cost factors, using the average wage level in the manufacturing sector (WAGE) in 1998 as a variable. On the basis of the reasoning that start-up firms tend to select locations that have lower labor costs, we expect that the level of labor costs affect the start-up ratio negatively (Ashcroft *et al.* [1991], Gerlach and Wagner [1994], Santarelli and Piergiovanni [1995], Audretsch and Vivarelli [1996], Kobayashi [2004]).

H 2: The start-up ratio is lower in regions where the average wage is higher (WAGE -).

For start-up firms, human capital factors are related to the availability of both entrepreneurs and a labor force. Both aspects involve several quantitative and qualitative measures. Among the quantitative measures, the unemployment ratio is the most commonly used factor in the previous studies. There are two conflicting views regarding the effect of the unemployment ratio (“push hypothesis” and “pull hypothesis”). Therefore, we present the following two conflicting hypotheses:

H 3a: The start-up ratio increases with increase in the unemployment rate (UNEMPL +).

H 3b: The start-up ratio decreases with decrease in the unemployment rate (UNEMPL -).

As qualitative measures of human resource factors, we use the ratio of the number of university graduates to the population over 15 years of age (UNIV) and the ratio of the employment in professional and technical occupations to the total employment (EXPERT). As in previous literature (Guesnier [1994], Hart and Gudgin [1994], Keeble and Walker [1994], Armington and Acs [2002], Acs and Armington [2004]), we hypothesize that these variables have positive effects on the start-up ratio because of the accumulation of qualified human capital.

H 4a: The start-up ratio increases with the ratio of the number of university graduates to the population over 15 years of age (UNIV +).

H 4b: The start-up ratio increases with the ratio of the employment in professional and technical occupations to the total employment (EXPERT +).

It is considerably difficult to measure the regional characteristics of financial factors. In accordance with the previous literature (Moyes and Westhead [1990], Ashcroft *et al.* [1991], Guesnier [1994]), we use the ratio of the number of householders (households with their own houses) to the total number of households (MYHOME) as a proxy for the possibility of financing the start-up. We hypothesize that the higher this ratio, the easier it is to start a new business because the householders can raise funds more easily by using their houses as collaterals.

H 5: The start-up ratio increases with the ratio of householders to the total number of households (MYHOME +).

We use the business density (the number of establishments per square kilometer) (DENS) and the proportion of manufacturing plants among all establishments (MRATIO) as the indicators of industry agglomeration and industry structure, respectively. With regard to industry agglomeration, we assume that the higher the business density, the higher is the start-up ratio. This is because of positive agglomeration effects such as the accumulation of production factors, availability of information, and technology spillovers. With regard to industry structure, several studies suggest that regions characterized by a high proportion of the manufacturing sector tend to have a lower start-up ratio. Therefore, we present the hypothesis that a larger proportion of manufacturing plants affects the start-up ratio negatively.

H 6: The start-up ratio is higher in regions with higher level of industry agglomeration (DENS +).

H 7: The start-up ratio is lower in regions with a high share of the manufacturing sector in the total number of establishments (MRATIO -).

Among other factors, we focus on the average size of establishments, traffic access, and public services. The average size of establishments is supposed to be a measure of the barriers to entry. Moreover, regions characterized by a high proportion of small businesses are expected to have business environments favorable for small businesses. For these reasons, we expect that a large average business size affects the start-up ratio negatively. In this paper, we define the average business size (AVESIZE) as the average number of employees in all establishments in all sectors.

H 8: The start-up ratio is higher in regions with smaller average size of establishments (AVESIZE -).

Traffic access is expected to affect the start-up ratio, because regions with better traffic access are favorable to secure essential production factors and supply goods and services. In this paper, we use the variables for the railway (Shinkansen Express stations) and the roadway (highway interchanges) traffic access. See the full paper for more detail.

H 9: The start-up ratio is higher in regions with better traffic access (SHINK +, HIWAY +).

In this paper, we use the log of the amount of per capita public expenditure (PUBEXP) and the number of local civil servants per hundred residents (CIVSERV) as the variables to represent the weight of the public sector. Public services are expected to affect the start-up ratio positively (Papke [1991]) or negatively (Reynolds [1994]). Therefore, we present two conflicting hypotheses.

H 10a: The start-up ratio is higher in regions with a higher weight of the public sector (PUBEXP +, CIVSERV +).

H 10b: The start-up ratio is lower in region with a higher weight of the public sector (PUBEXP -, CIVSERV -).

### 3-2. Data

Table 1 lists the original data sources of the variables. The dependent variable, i.e., the gross start-up ratio during 1996-99 was calculated from the aggregated regional data of the “Establishment and Enterprise Census 1999.” The data for all the independent variables, except for those of traffic access, are obtained from the “Regional Economy Database,” April 2004 version, published by Toyo Keizai. This database provides regional data from several official and other statistical sources for each municipality, as

of April 2004. The original sources of these data are official statistics such as “Population Census,” “Establishment and Enterprise Census,” and “Census of Manufacturers.”

The data samples used in the analysis presented in this paper are from 3,123 municipalities and 185 economic areas, as of April 2004. Economic areas, which divide each prefecture into 4 regions and contain 17 municipalities on an average, are defined in accordance with the regional segmentation presented in the “2002 National Survey of Prices.” Based on this definition, economic area data were calculated by aggregating the municipality data. We expect the economic area defined in this manner to be an adequate proxy for the local market area.

Table 2 about here

Basic statistics regarding the municipality and economic area samples are presented in Table 2. The mean and the median of the regional gross start-up ratio for the 3 years from 1996 to 1999 are 8.2% and 7.5% at the municipality level and 9.8% and 9.5% at the economic area level, respectively. The maximum gross start-up ratio among the municipalities is 62.8% and that among the economic areas is 18.9%. The disparities in the start-up ratio among municipalities are very large.

#### **4. Analytical Results and Discussion**

##### 4-1. Municipality Sample

Table 3 about here

Table 3 lists the regression results of the municipality sample. With regard to the results of the WLS analysis, except for the householder ratio (MYHOME) and the average size of establishments (AVESIZE), the signs of the coefficients of all the variables are as expected and most of these coefficients are statistically significant. These results support Hypotheses 1, 2, 3a, 4a, 4b, 6, 7, 9, and 10b, but do not support Hypotheses 3b, 5, 8, and 10a.

The results of OLS regressions reveal trends similar to those observed in WLS analyses; however, the coefficients and their levels of significance are reduced, and the coefficient of CIVSERV loses significance. Both the WLS and OLS models presented here have sufficiently high explanatory power.

##### 4-2. Economic Area Sample

Table 4 about here

Table 4 presents the estimation results of the economic area sample. With regard to the results of the WLS analysis, the coefficients of average wage (WAGE), unemployment ratio (UNEMPL), ratio of university graduates (UNIV), the ratio of employment in professional and technical occupations (EXPERT), and relative number of local civil servants (CIVSERV) have the expected signs and are statistically significant. The coefficient of the average size of establishments (AVESIZE) is also significant but its sign is contrary to our expectation. The coefficients of householder ratio (MYHOME), business density (DENS), and proportion of manufacturing plants (MRATIO) are significant in half of the equations, while the signs of the coefficients of MYHOME and DENS are contrary to our hypothesis. The coefficients of remaining variables are not statistically significant. These results support Hypotheses 2, 3a, 4 a, 4b, 7, and 10b, but do not support Hypotheses 1, 3b, 5, 6, 8, 9, and 10a.

The results of the OLS regressions reveal trends that are essentially identical. The coefficients and levels of significance of some variables are lower but the coefficients of MYHOME and MRATIO are now significant in all equations. Both the WLS and OLS models presented here have sufficiently high explanatory power.

#### 4-3. Discussion

The results of the economic area level analysis differ from those of the municipality level analysis in the following aspects:

- 1) The effect of population growth is not significant,
- 2) The effects of the householder ratio and proportion of manufacturing plants are significant only in some regression equations,
- 3) The effect of business density is negative (significant only in certain equations),
- 4) The effect of traffic access is positive but not significant,

The observation that the estimated coefficients of some variables become insignificant may be interpreted to imply that these variables have location-specific characteristics and do not affect start-up activities in a larger region. In the full paper, we present a detailed discussion about the negative effect of business density on the start-up ratio in the economic area analysis.

The results presented in this paper support those obtained in the previous literature with respect to the positive effect of demand factors, the negative effect of cost factors, the positive effect of the unemployment rate (“push hypothesis”), the positive effects of

other human resource factors, the effects of industry agglomeration and industry structure, and the positive effects of traffic access. However, the negative effect of the householder ratio and the positive effect of the average business size, which are contrary to our hypotheses, are not in line with the results of almost all the previous studies. We present some interpretations of these unexpected effects in the full paper.

## **5. Concluding Remarks**

This paper is the first detailed analysis on the regional factors affecting the start-up ratio using segmented regional data, at the municipality and economic area levels in Japan. In this paper, we hypothesized that the regional gross start-up ratio is affected by demand, cost, human resources, financial, industry agglomeration and structure, and other factors (average business size, traffic access, and weight of the public sector).

The results reveal that the factors that cause an increase in the start-up ratio are high population growth, low wages, high unemployment ratio, low householder ratio, high ratio of university graduates, high ratio of employment in professional and technical occupations, high business density, low proportion of manufacturing plants, large average business size, good traffic access, and low weight of the public sector.

These results imply that cost factors are not significant obstacles to business start-ups and that the accumulation of qualified human resources is an important factor for start-ups. In other words, in order to promote business start-ups at the regional level, it is more important to accumulate qualified human resources than reduce the costs of start-up and operation and provide loans.

Despite of some contributions to the understanding of the regional factors of the start-up ratio, this paper has certain limitations. The first limitation is related to the difficulty of definition of a region as an analytical unit. The second limitation is that we could not differentiate among industries due to the limited availability of data.

## **Endnotes**

- 1) The definition of economic areas is based on that stated in the “2002 National Survey of Prices,” wherein each prefecture was divided into 4 economic areas on an average, and 185 economic areas were defined for the entire country.
- 2) According to the Standard Occupation Classification of Japan, “professional and technical occupations” include the occupations of various types of scientists and engineers; occupations in medical and health care services, such as the professions of

doctors, pharmacists, and nurses; occupations in social welfare services; occupations in legal services, such as the profession of lawyers; occupations in business support services, such as the professions of accountants and management consultants; and occupation of teachers and artists.

Table 1: Definitions of Variables and Original Data Sources

| Variables | Definitions (units / years)   | Original Data Sources                                  |
|-----------|---|--|
| STARTR    | gross start-up ratio (1996-99): # of business openings (1996-99) / total # of establishments in 1996 (private businesses in the non-primary sector) | Establishment and Enterprise Census                    |
| GRPOP     | Rate of Population Growth (1990-95)   | Population Census                                      |
| WAGE      | average wage in manufacturing (thousand yen) (1998)   | Census of Manufactures                                 |
| UNEMPL    | Unemployment ratio (1996)   | Population Census                                      |
| UNIV      | Ratio of university graduates to the population (older than 15 years old) (2000)  | Population Census                                      |
| EXPERT    | Ratio of employment in professional and technical occupations to the total # of employment (1995)   | Population Census                                      |
| MYHOME    | Ratio of households with own housings (1995)  | Population Census                                      |
| DENS      | Business density: # of establishments per km <sup>2</sup> (1995 / 96)   | Population Census, Establishment and Enterprise Census |
| MRATIO    | Share of manufacturing plants to total number of establishments (1996)  | Establishment and Enterprise Census                    |
| AVESIZE   | average establishment size: average # of employees of private establishments in the non-primary sector (1996)                                       | Establishment and Enterprise Census                    |
| SHINK     | Dummy for railway access, taking on the value of 1 if there is a station of Shinkansen Express and 0 otherwise                                      |  |
| HIWAY     | Dummy for highway access, taking on the value of 1 if these is a highway interchange and 0 otherwise  |  |
| PUBEXP    | Public services: log of public expenditures per capita (1996)   | Survey of Public Account in Municipalities             |
| CIVSERV   | Public services: # of local civil servants per 100 inhabitants (1996)   | Survey of Wages of Local Civil Servants                |

Notes:

- 1) Regional data for the empirical analysis except for STARTR, SHINK and HIWAY were obtained from "Regional Economy Data CD-ROM", Version April 2004 (Toyo Keizai). SHINK and HIWAY were prepared from a Japanese Map.
- 2) With regard to the analysis using economic area data, SHINK and HIWAY are the share of the number of inhabitants in the municipalities with a Shinkansen station or a highway interchange to the total number of inhabitants in the economic area, respectively.

Table 2: Basic Statistics

## A. Municipality Data

| Variables | Mean   | Median | St.Dev. | Min.   | Max.    | Observations |
|-----------|--------|--------|---------|--------|---------|--------------|
| STARTR    | 0.082  | 0.075  | 0.052   | 0      | 0.628   | 3,123        |
| GRPOP     | -0.005 | -0.014 | 0.064   | -0.253 | 0.592   | 3,123        |
| WAGE      | 3,467  | 3,346  | 1,069   | 190    | 9,890   | 3,038        |
| UNEMPL    | 0.033  | 0.030  | 0.016   | 0      | 0.178   | 3,123        |
| UNIV      | 0.076  | 0.065  | 0.044   | 0.011  | 0.335   | 3,122        |

# **IMPLEMENTATION OF THE SMALL AND MEDIUM INDUSTRIES EQUITY INVESTMENT SCHEME IN NIGERIA**

**By**

**Grace Tola Olutunla**

**General Studies Unit

## **Abstract**

Many SMIs in Nigeria have become moribund majorly because of poor funding. The CBN established the SMIEIS in 2001 to provide equity finance for the SMIs. The CBN directs all banks to contribute 10% profit after tax to the Scheme. The goal was to relieve the SMIs from borrowing and interest burden. The implementation of the Scheme is below expectation. By the end of 2004, less than 50% of the 89 banks complied with the CBN directive. Only 31% of the Scheme's ₦28.8 billion was invested in the SMIs.

This paper identifies the challenges facing the Scheme. Data were collected using a sample of six banks – headquarters and two private fund operators. Findings reveal that the number of applications approved was on the average 4.3% of the applications received. The reasons given for declining applications, ranked in order of prominence, ranged from bad feasibility studies, poor management skills and lack of proper accounting to poor character checks. Non-full disbursement of approved amounts was due to incomplete/improper documentation and diversification of funds. Some banks lacked interest because project review was demanding, costly and took long and also there was envisaged difficulty at point of disinvestment.

Sectoral distribution of funded projects was more in favour of the productive sector with manufacturing dominating.

This paper recommends that all stakeholders in SMIEIS should develop strategies that will enable entrepreneurs meet the requirements of the banks and the PFMs. The banks should be more responsive and pro-active in implementing the Scheme.

## **Introduction**

Studies of Entrepreneurship and small and medium industries (SMIs) development worldwide have established lack of adequate capital as a basic and major constraint (Bolton 1978; Fatunla 1989, Olutunla (2001), etc. Many of the SMIs in Nigeria have become moribund owing partly and oftentimes largely to poor funding. To solve the financial and related problems

of the SMIs, the Central Bank of Nigeria (CBN) established the Small and Medium Industries Equity Investment Scheme (SMIEIS) as a voluntary initiative of the Bankers' Committee and it was approved on 19<sup>th</sup> June, 2001. The Scheme requires all banks in Nigeria to set aside 10% of their profit before tax for equity investment in small and medium scale industries.

The SMIEIS defines SMI as any industry with an asset base ranging between ₦1.50 million and ₦200million including working capital but excluding cost of land and a workforce of 11 to 300 workers (Report of NCI – 14, 2003). In addition to providing finance, the Scheme requires banks to identify, develop and package viable industries with enterprising customers. The goal of the Scheme is to relieve the SMIs from borrowing and consequently relieve them from interest and other charges. The advantages of the Scheme include provision of risk capital, financial advisory services and entrepreneurial management to SMIs. Initially, only commercial banks participated in the Scheme. Recently in the last one year, private fund managers (PFM) have been incorporated to manage the Scheme, pooling the idle equity funds from several commercial banks to administer and reach out to more SMIs.

Though very laudable in its objectives, the implementation of the Scheme seems to be falling below expectation. In year 2004, out of eighty-nine (89) banks operating in Nigeria, only forty-four (44) had invested in this Scheme. Over 50% of the banks were yet to comply with the CBN directive. Out of the N28.8 billion set aside by the complying banks, only about N9 billion or 31% was invested in SMIs (Business Day, 2004). Obviously, the implementation of the Scheme is facing certain challenges that are increasingly creating problems to the success of the Scheme. This exploratory study identifies some of the challenges and discusses the Scheme's achievements, constraints and prospects for better and higher level of effective implementation.

## **Methodology**

This study is exploratory in scope. Originally conceived as a paper based on the case study of one bank by Ogunleye (2004), it has been expanded to a sample of size 8 i.e. randomly selected six (6) banks and two private fund managers (PFM). The headquarters of the banks were selected and located in Lagos, the commercial nerve-centre of Nigeria. Normally, all applications from branches go to the headquarters for processing and approvals. Time coverage for the study was from the inception of the Scheme (2001) to the time of interview. The data for the case study Bank (labelled A in the Tables) was collected in 2004, while the data from the other five banks (labelled B to F in the Tables) and the two PFMs (labelled G & H) were collected in February 2005.

Preliminary discussions were made with the Corporate Affairs managers in the selected bank headquarters and also with the PFMs. Thereafter, structured questionnaires were completed by them. Seven (7) were self administered, while only one responded by hand mail. Any ambiguity was cleared over telephone calls.

Data were collected on variables such as the number of applications received, the number approved, the reasons for declining applications, the total amount of equity participation requested and the proportion granted. The questionnaire also sought information on sectoral distribution of the beneficiaries as well as the level and type of assistance rendered to the funded SMIs. Suggestions were also sought on how to make the Scheme effective and successful.

## Data Analysis and Findings

The numbers of applications received and approved are as detailed in Table 1. Analysis shows that the number of applications approved ranged between 2% and 17% of the number of applications received with average of 4.3%.

Table 1 here

Surprisingly the proportion in the category of the private fund managers was only 3% despite the large number of applications received by them. It should be noted however that a very large proportion of the applications were still being processed. Others have been declined outright. The numbers of applications declined by the reasons given are as presented in table 2(a). Table 2(b) shows the ranking of the reasons – with score of 5 representing the most common reason and 1 the least common reason. Both tables confirm that the four most prominent reasons given were bad feasibility studies, poor management skills, lack of proper accounting and poor character. The two reasons that were of least importance were business not in strategic focus of the bank and business owners neither wanting to dilute equity nor share control.

Tables 2(a) & 2(b) here

Table 3 presents the data on the amount of equity participation requested, approved and disbursed. There is not much variation between the amount requested by the SMIs and the amount disbursed. Approval was 72% of request while disbursement was 93% of approval. This shows that there was not much frivolity in the application requests. More importantly, it emphasizes the fact that there was adequate supply to meet the demand for equity funds.

Table 3 here

For the few cases of non-disbursement, the most frequently cited reason for incomplete disbursement of the amount approved was incomplete / improper documentation by the applicants. Other reasons were non-fulfillments of conditions precedent to draw down, poor business/project viability, inability of entrepreneurs to demonstrate good understanding of the business and diversification of capital funds.

The sectoral distribution of the equity fund beneficiaries is presented in tables 4(a) and 4(b)

|                       |
|-----------------------|
| Tables 4a and 4b here |
|-----------------------|

The spread of the sample data (table 4a) is at variance with the spread of investment in the population data for the whole country presented in table 4(b). In Lagos (from where the sample was taken), equity investments were more in the services related sector (having 67.35% of the 49 projects funded by the respondents). The reverse was the case in the distribution for the whole country. Both the number of projects (67.85% of the 168 projects) and the value of investments (65.41% of ₦8,531 billion investment) were in favour of the productive sector, with manufacturing dominating. The service related sector had only a third of the equity investment of the Scheme. Incidentally, Lagos State had the highest with its total investments put at ₦5.045 billion in 110 projects representing 80.29% of total equity investments in the country (Business Times, 2005). Caution should be taken to ensure that the Scheme is used to develop SMIs rather than services. SMIs are normally disadvantaged to get funding because of the usually long gestation period and slow rate of returns.

Apart from financial investment in the SMIs, it is encouraging to note that both the participating banks and the PFMs provide other development support such as financial advisory services, entrepreneurial management assistance and board membership. However the PFMs

were more responsive to these needs of the SMIs. While the PFMs provided these 3 types of assistance in all the 34 SMIs in which they had equity interest, the banks gave financial advisory and management assistance to only 55% of the SMIs and had Board membership in 89% of the SMIs where they invested. Furthermore, data reveal that both the banks and the PFMs put in minimum of 5% to 40% and maximum of 33% to 51% as equity while the Board membership was minimum of 5% to 50% and maximum of 40% to 50% of total.

In order to improve the level of effective implementation, it is important to know the requirements that the participating banks and equity fund managers expected the Scheme applicants to meet. The requirements were listed in order of importance. Scoring the most important three (3) and the least important one (1), the analysis of responses revealed that 'feasibility study and project viability' ranked highest with 14 points, 'entrepreneurial managerial competence' with 9 points was second, while 'market analysis' was 3<sup>rd</sup> with 4 points. In the 4<sup>th</sup> rank, with 3 points each, were 'good character', 'corporate governance', 'incorporation papers' and 'business growth'. The requirements that came last, each with 1 point, were 'strategic focus' and 'ability to meet the guidelines'.

To compare the ability of the applicants to meet the requirements expected of them, the banks were to state the number of applicants that met the requirements. Analysis and results show that by and large, the ranking of the ability matched that of the expectations. Satisfactory feasibility study, good accounting procedure, project viability and reliable management skill topped the ranking. The number of applicants meeting the above ranked requirements were 127, 114, 111 and 201 respectively. Satisfactory character check and good community were last with 74 and 39 applicants meeting these two requirements respectively.

There is the widely held view that banks prefer to pay penalties rather than participate in the Scheme. Our sample and findings do not confirm this view. Only two banks responded that, if given the option, banks would prefer to pay penalty. The remaining 5 respondents including the two PFMs felt that banks would not prefer to pay penalty. The banks which felt that penalty option would be preferred to participation gave many reasons for their opinion: project review was demanding and takes long time; associated cost of processing, management and documentation was discouraging; equity investment was risky and income slow, as well as difficulty at point of disinvestment and the insincerity of promoters.

The respondents offered suggestions for future review of the CBN Guidelines for the Scheme. Major among these was that the lower limit of number of employees and/or capital investment should be less or removed to accommodate micro enterprises to qualify for the Scheme; that micro-finance institutions should be included in the eligible sectors so as to create access to small borrowers. Other important suggestions were that the CBN Guidelines should remove the rigidity of sectoral allocation for the Scheme to include more sectors and that the Scheme should include viable start – up projects. Furthermore, aside from finance, the guidelines should address other SMIEIS problems like infrastructure particularly electricity supply; education of promoters on basis of management skills; and emphasis should be based on SMEs with comparative advantage to the nation.

Only 2 of the 8 banks and PFMs agreed that the entrepreneurs were adequately aware and interested in the Scheme. The remaining 6 operators or 75% felt that there was not enough awareness by the entrepreneurs. Generally, 62.5% of the banks/PFMs felt that the Scheme had been successful while the remaining felt the Scheme had only partial or no success.

## **Implications for SMI Development**

An approval rate of 4.3% confirms that the Scheme is failing to achieve the objectives of setting it up. This implies that ailing and moribund SMIs are not being revived. Entrepreneurs and the SMIs are still left to seek financial assistance through borrowing often with high interest rates. Even loan assistance may never be available to them as the reasons given by the banks for rejecting applications remain the same since the 1970s i.e. bad feasibility reports and non-viability of projects, poor management skills and lack of proper accounting procedures.

This study highlights the significant role being played by the private fund managers since they entered the Scheme in the last one year. The PFMs are taking on those challenging roles that the banks have refused over the years. In addition to their financial participation, they have assisted the SMIs in financial as well as management advisory services. These and their major participation in Board membership augur well for the development of the SMIs. Through Boardroom monitoring, the past practices of fund diversification and bad financial management will give way to efficiency, profitability and growth of the SMIs. The PFMs may ultimately be the hope of the entrepreneurs and SMIs in successful implementation of the Scheme in their favour. It is recommended that more private fund managers should be encouraged to incorporate and use the huge funds available in the SMIEIS to develop the SMIs.

The sectoral distribution of the SMIEIS investment is encouraging as about two-thirds are in the productive sector while about one-third are in the services-related sectors of the SMEs (table 4). Investments in the real sector usually have longer gestation period. Unfortunately, the banks traditionally are more interested in financing short-term projects with quick profit returns. The SMIEIS, particularly with the emergency of the PFMs, is addressing this challenge and the trend of participating more in favour of the real sector should continue. This has important

impact for sustainable development and growth of the industrial sector in emerging economies like Nigeria.

Even though the requirements demanded by the banks to approve SMI applications for funding are high and unrelenting over the years, they are very important for the capacity building of the entrepreneurs and SMI managers. The requirements sensitize the awareness that more attention should be focused on the training of entrepreneurs and SMI managers to improve their capability in presenting bankable investment proposals and feasibility study reports, to train entrepreneurs in accounting principles and generally to raise their organizational skill and managerial capacity. To this end, this study recommends the establishment of some Centres and Institutes of Entrepreneurship in selected Nigerian Universities to focus on Entrepreneurship/SME research and training. Such institutions can seek partnerships with relevant government ministries and agencies like Small and Medium Enterprises Development Agency (SMEDAN) and National Directorate of Employment (NDE). The government and corporate bodies can also establish Entrepreneurship Chairs for research professors (Olutunla, 2001)

Hitherto, the micro-enterprises (with less than ₦1.5million capital and employing less than 11 workers) have been excluded from qualifying for the SMIEIS funding. Including micro industries in the CBN Guidelines for the Scheme will imply more growth for the SME sector, reduction of poverty and unemployment. More micro industries funded by the SMIEIS will grow to become the springboards for SMIs and large industries in the country.

While it is recommended that viable start-up projects should be included in the Scheme, the Guidelines should not be broadened to include all sectors of all sizes. That will negate the objective of the Scheme. Widening the Guidelines qualifications to include more services

sectors (particularly trading) and the large firms will stifle out the SMIs from the unique benefits of the Scheme.

The option of penalty payment by non-participating banks may not augur well for SME development. Rather, it will give the opportunity to the reluctant banks not to invest in the Scheme. Already some banks try to make a way out and try to fulfill the righteousness of the CBN directive through inside lending to their own directors or relations having interests in SMIs. In fact some banks participate as preferential shareholders. However, such practices face disqualification and sanctions when discovered by the CBN. The important thing is that the banks should contribute, support their own initiative and faithfully implement the Scheme to achieve the desired set goals.

## **Conclusion**

The SMIEIS is a very well conceived and laudable Scheme. Though the pace of implementation is slow and level of equity investment is extremely low, the Scheme should be encouraged to succeed. Given the chance of time to mature, it will contribute immensely to the development of SMEs in Nigeria. The banks should be more pro-active, fulfil their obligations and use the huge funds available to finance the SMIs. More private fund managers should be established to participate in the Scheme.

Government, Universities, the organized private sectors (like NACCIMA, NASSI and NASME), NGOs in partnership with international development agencies (like UNDP) should all contribute to the training and enhancement of the managerial capacity of entrepreneurs and SMIs. With proper and effective implementation of SMIEIS, the Scheme will play the expected role in SMI development in particular and generally in the employment generation, poverty

alleviation and overall economic development of Nigeria. Indeed, it will become a model for other developing nations of the world.

## Gender differences in perceived success among business owners and corporate managers <sup>1</sup>

To better understand potential explanations for gender differences in organizational performance, this paper examines how owner-managers and corporate managers define success. The work also documents how perceptions vary systemically by gender. The study draws on a sample of 326 Canadian business owners and 405 Canadian corporate managers. Four factors were evidenced in the two sample groups (personal fulfillment/personal well-being; balance/balanced life; financial outcomes/financial rewards; and market acceptance/organizational performance) and appear to be similar in structure. One factor, *workplace culture*, was significantly different. This factor reflects success criteria that includes a supportive work culture, reputation of organization, competent colleagues, professional autonomy and employment flexibility. The factor speaks to the benefits of being employed in a large organization that affords employment flexibility and opportunities to work with many individuals. Gender differences in perceived success were noted. Female managers were more likely than male managers to value intrinsic criteria in both the personal and professional realms. Women business owners also accord higher values (than men) to success criteria associated with personal fulfillment and balance. Recommendations about the next steps in the research are outlined.

What is success? Previous research has found that individuals define “success” differently. This empirical study compares, across gender, how owners of small firms and senior corporate executives define success. Within the entrepreneurship and small business literature, “success” is often delineated using financial criteria such as revenue, employment, productivity, profit, or return on investment (Newton, 1995, 2001; Freel, 1999; Kalleberg et al., 1991; and Abraham, Karns, and Shaw and Mena, 2001). Organizational theorists have also traditionally taken a narrow perspective on success, with success defined in terms of remuneration and hierarchical level (Jaskolka, Beyer & Trice, 1985; Melamed, 1996; Stroh, Brett & Reilly, 1992). Business owners and employees, however, may not define success in

---

these terms. The objectives of this research therefore is to examine empirically the dimensions of perceived success, to test explore how success dimensions used by business owners and corporate managers differ, and to identify potential gender differences across the two groups.

Briefly, gaining a better understanding of the cognitive aspects of success is important for several reasons. While pecuniary motives are often assumed to be the driver of organizational decision-making, traditional financial indicators do not consider non-pecuniary outcomes that individuals may value. It is also conceivable that the definition of “success” may vary systemically across gender and across other salient dimensions. These potential differences may help to explain documented differences in small firm performance and career outcomes (Industry Canada, 2005, Conference Board of Canada 2000). The paper therefore begins with a literature review, followed by an overview of the research methodology. The research findings follow. The paper closes with a discussion about next steps in the research.

### **Review of Literature**

Success appears to be complex, multi-dimensional and transitory: perceptions may evolve over time, may be role sensitive, and likely include pecuniary and non-pecuniary outcomes. Several researchers have sought to identify the dimensions of success. In the context of larger firms, Gattiker and Larwood (1986) identified five facets of success; criteria that reflect work role, interpersonal, financial, hierarchical and life success attributes. Schein (1975) defines professionals’ perceptions of success as “career values”, values that include: autonomy/independence; security/stability; technical-functional competence; general managerial competence; entrepreneurial activity; service or dedication to a cause; pure challenge and lifestyle. Similarly, Derr (1986) identifies five career success orientations: getting ahead,

---

Allan Riding and Roland Thomas and (Carleton University), and Erwin Dreessen and Don Harrison (Small Business Policy Branch, Industry Canada).

getting secure, getting free, getting high on challenge and adventure, and getting balanced. Parker and Chusmir's (1992) analysis of 42 success criteria led to the identification of six success factors; these include status/wealth, contribution to society, family relationships, personal fulfillment, professional fulfillment, and security.

Employing a women only sample of professionals, Slipowitz (1992) reports on the interface between personal, family, and entrepreneurs' social environments. Success was seen as a process rather than a final outcome. More recently, Sturges (1999) categorized 3 types of success criteria: internal, external and intangible. "Internal" success criteria include attributes such as accomplishment, personal achievement, enjoyment, integrity and balance. "External" success criteria focus on hierarchical position and compensation. "Intangible" criteria of success include personal recognition and influence. Similarly, Nabi (2001) identified two underlying dimensions of subjective success: intrinsic job success, which includes enjoyable work, respect and support and extrinsic job success, which focuses on financial rewards and promotional opportunities.

The above observations are echoed in the small business literature. In a cross-cultural study of business owners, Ray and Trupin (1989) suggest five categories of "entrepreneurial success" including: *financially-orientated entrepreneurs*, typified as young ventures with significant growth in a short period; *craftsman-inventors* described as older, slow-growth firms; entrepreneurs that sought *independence*; those that framed their work as a "*calling*" – young ventures with significant growth; and, entrepreneurs that exhibited a sense of *wonderment that they became entrepreneurs*. More recently, Orser (1997) reports on 6 dimensions of success among Canadian business owners: family, financial security, mobility, personal well-being, emotion and the environment. Employing a female-only sample of women entrepreneurs, Lee-

Gosselin and Grise (1990) identified three types of success criteria: financial aspects of the firm (e.g., increased revenues, profits, earning income); the owner/managers' environment (e.g., people have confidence in the company, being visible and known in the community); and respondents' personal frameworks (i.e. having control of their own business or market).

Taking a broad perspective of the literatures suggest that “success” reflects both external factors (for example, historical period, nationality, sector, employment structure and organizational setting) and factors internal to the individual (e.g., life cycle or life stage, experience, education, occupation, employment level, wealth, and gender). In addition, the literature also records definitions of success that encompass personal (e.g., self-fulfillment, freedom and work flexibility) and commercial dimensions (e.g., business growth, profit) (Ray and Trupin, 1989; Fagenson, 1993). These relationships are illustrated in Figure 1. These observations suggest the first set of propositions:

*H1: Multiple success criteria are important to small business owners and corporate managers. Success reflects personal and professional attributes and intrinsic and extrinsic attributes.*

## **The Effect of Gender on Perceived Success**

Empirical studies that examine gender differences in definitions of success report inconsistent results, results that may reflect a methodological bias. Those studies that have used global measures of success (e.g., “*How would you rate your overall success*”) have found no gender differences (Judge, Cable, Boudreau & Bretz, 1995; Nabi, 2001; Peluchette, 1993). Conversely, studies that have examined specific dimensions of success have documented a number of significant gender differences (Duxbury, Dyke & Lam, 1999, 2000; Dyke & Murphy, 1998; Kagan, 1993; Parker & Chusmir, 1992; Sturges, 1999). For example, Parker and Chusmir (1992) examined both gender and organizational level. Their results indicated that *personal*

*fulfillment* was more important to women than to men, amongst both managers and non-managers. *Security* was also more important to women managers than to male managers. Similarly, in a study of women and men nominated by others as successful, Dyke and Murphy (1998) found that women placed more emphasis on balance while material success was important to more men. In two large surveys of public service and high technology employees, Duxbury, Dyke and Lam (1999, 2000) found that women rated several success criteria as more important than men. These included balance, relationships on the job and moving through positions of increasing responsibility. In both studies, men rated being able to influence organizational direction as more important than did women. Similarly, Sturges (1999) found that women were more likely to emphasize internal criteria of success such as accomplishment and intangible criteria like recognition while hierarchical position was more important to men. Sturges (1999) argues that women focus on less tangible markers of success because traditional successes such as hierarchical advancement and high salaries are not readily available to them.

It is not clear if perceptions of success differ between small business owners and corporate managers. The literature does, however, hint that both workplace and gender influence perceived success. For example, in an investigation of perceptions of success among managers and non-managers, Parker and Chusmir (1992) noted that male and female managers differed significantly on two dimensions. Personal fulfillment and security were more important to women managers than to male managers. Among non-managers, no gender differences in the perceived value of security, professional fulfillment, and social contribution were found; however, women were more likely than men to value personal fulfillment and importance of family relationship. Men valued status and wealth more highly than women did. Women managers viewed status/health and professional fulfillment as more important than non-

managerial women. A broad perspective of this literature suggests that women are relatively more concerned about personal aspects of success while men are relatively more concerned with financial rewards. These observations are reflected in the following propositions:

*H2a: Women business owners place a higher value than male business owners on intrinsic personal success criteria.*

*H2b: Women managers place a higher value than male business managers on intrinsic personal success criteria.*

*H3a: Male business owners place a higher value than women business owners on extrinsic professional success criteria.*

*H3b: Male managers place a higher value than women business managers do on extrinsic success criteria.*

## **Research Methodology**

### **Sample Selection**

To test these propositions, complementary questionnaires were used to solicit the views of a sample of SME owners and a separate sample of corporate executives and managers. The development and design of the small business and corporate surveys are reported in Orser and Riding, 2004 and Dyke and Orser, 2005.

*Small business owners:* The sampling frame consisted of 1,002 SME owners drawn from a commercial database. The sampling was undertaken in two phases. Phase one entailed fax-back survey administered in spring 2001. Phase 2 entailed a telephone survey in winter 2003.<sup>2</sup> A total of 326 telephone surveys were completed in the 2003 fieldwork, a response rate of 46.2 percent of eligible respondents.<sup>3</sup>

---

<sup>2</sup> A comparison between the 2001 and 2003 samples was undertaken to investigate survivorship and non-response biases. Using standard Chi-square tests to examine the distributions of salient attributes, there were no statistically significant differences (p-value of less than 0.05) in owner or firm characteristics between the baseline data available in the sampling frame and the corresponding attributes of respondents.

<sup>3</sup> Of the 1,002 respondents in the 2001 WEI sampling frame, interviewers were unable to contact 234 respondents; 60 potential respondents were no longer in business. Of the remaining 707 eligible respondents, 223 refused to

*Corporate managers:* Two databases were used as a sample frame from which 5,924 names of corporate executives and managers were purchased from a data management firm. All held mid-level management to executive positions in private or government organizations that employed at least 500 people. The sample included all Canadian provinces, except Quebec. Since women are less likely to hold executive positions, the sample was augmented with the names of 76 women business leaders from Canada's Top 100 Most Powerful Women. The analysis is based on 545 respondents including 281 men and 261 women reflecting a 9 percent response rate; 24 responses were received from Canada's Top 100 Most Powerful Women, a 32 percent response rate.

### **Sample profiles**

Respondents' attributes are summarized in Table 1. Male business owners accounted for two-thirds of the sample (67.3 percent). Most small business owners were well educated, a finding that appears to be consistent among self-employed Canadians across the four Western provinces surveyed. Approximately half of the business owners surveyed were less than 50 years of age with the majority falling into the 30 to 49 year age group. Only 2 percent of respondents were less than 30 years of age. Three-quarters of those surveyed created or participated in the creation of the business. The sectoral breakdown is not representative of the population of SMEs as a whole: respondent firms are relatively highly concentrated in the services and trade sectors, with few establishments in the goods-producing sector. Sixty-five percent of the respondent

---

participate, 142 failed to return any of more than three calls and another 16 were eliminated for miscellaneous reasons. This reflects a 46.2% response rate among eligible respondents or 32.6 percent response rate within the sampling frame

firms employed 5 or fewer full-time equivalents (FTE); 28 percent of the firms employed 5 to 20 employees or FTEs; while 7 percent employed more than 20 FTEs.<sup>4</sup>

*Corporate managers:* Similar to the sample of small business owners, corporate respondents were well educated; the majority (59 percent of females and 42 percent of males) had university degrees. On average, respondents had over a quarter of 25 years work experience, worked with their current employer for over 13 years and earned in excess of \$110,000. On average, respondents were responsible for 23 employees. Six in ten respondents were employed in executive roles.

### **Measuring perceived success**

*Small business owners:* To test the above propositions, the questionnaire asked business owners to rate on 5 point scales the importance of each of 18 criteria that they might conceivably use to evaluate success. To explore the construction and value of the success criteria, factor analysis using principal components with varimax rotation was applied to 14 success criteria scales.<sup>5 6</sup> The results drawn from the small business owner sample are shown in Table 2. The analysis suggested four factors that together explained 56.7% of the variation. In summary, the four-dimensional construct reflected aspects of success associated with market acceptance, self-fulfillment, balance, and financial outcomes.

---

4 The proportion of firms with less than 5 employees is likely less than in the general SME population if one considers the profile of employer businesses and self-employed. For example, 35 percent of the firms in the sample used here reported more than five employees. Industry Canada (2003) reports that 42 percent of the 1.0 million Canadian business establishments (or employer firms) employ more than 5 people. This does not, however, take into account approximately 2.3 million self-employed individuals, 64 percent of which have no paid help.

5 Only 14 of the 18 criteria were entered into the principal component analysis. The three variables pertaining to employees (e.g., employee relations, employee productivity, creating employment) and one variable pertaining to external investment (e.g., investor relations) were not used as they were not relevant to non-employer firms. This is because most owners of non-employer firms responded that these scales were “not applicable”.

6 No additional factors with Eigenvalues in excess of 1.0 were identified; examination of the Scree plot also suggested that a four factor solution was reasonable. In addition, each of the four factors included scales that loaded on the factor with loads near or above 0.8. According to Stevens (2002), this is a desirable property in principal component analysis.

F1: *market acceptance* is commercial and incorporates five variables that correlate with the extent to which the business' products or services have gained acceptance including product or service quality, market acceptance, customer relations, environmental impact and operating performance.

F2: *personal-fulfillment* is associated with intangible, intellectual scales of spiritual well-being, pursuit of intellectual activities, etc. and is inherently personal. Variables included pursuing intellectual activities, spiritual well-being, maintaining professional autonomy, environmental impact and community relations. The scales that most closely relate to this factor pertain to the owners' personal, inner, feelings.

F3: *balance* differs from the second in that it reflects relationships in the business and household environments. The variables include maintaining personal relationships, work life balance, personal goods acquisition and customer relations.

F4: *financial outcomes* are again commercial. The variables that load highly on this factor included profitability, generating income, operating performance and personal goods acquisition.

These four factors appear to be intuitively sound and support the argument advanced by Sekaran and Hall (1989) regarding "multiple-role relationships" in determining criteria of success. Indeed, it appears that Canadian business owners perceive success as multi-dimensional. Statistically significant gender differences were also noted in the values that owners accord the various dimensions of success. Women business owners indicated statistically significant (at p-values of 0.063 and 0.022, respectively) and higher values (than men) to success criteria associated with *personal fulfillment* and *balance*. Whereas the weightings of these two factor scores were positive for women, the average factor scores for male business owners were negative. These findings are consistent with the previous results that suggests women business owners accord higher value to maintaining customer and personal relationships, spiritual well being and work life balance. These results also support arguments that women business owners are more likely than their male counterparts to value success criteria associated with the personal dimension. In addition, gender differences were noted in *market acceptance* (e.g., product or service quality, market acceptance, customer relations, environmental impact and operating performance) at a p-value of 0.102. Finally, no significant

gender differences were noted regarding success criteria pertaining to *financial outcomes* (e.g., profitability, generating income, operating performance and personal goods acquisition). These results support the argument that most business owners are concerned about their firm's operational results.

**Corporate managers:** Principal components analysis was also used to examine the underlying structure of 24 success criteria associated with corporate employment.<sup>7</sup> Two analyses were undertaken. The first employed a forced 4-factor solution. The 4-factor solution explained 48 percent of the variance in scores.<sup>8</sup> A second analysis used the traditional test for factor inclusion of an Eigenvalue greater than one. This analysis produced a 6-factor solution that explained 57 percent of the variance in scores. Since the six-factor solution captured more of the variance in success criteria, it was used in subsequent analyses. The factor loadings for both solutions can be found in Table 3. The 6-factor solution provides support for the hypothesis that success reflects personal and professional attributes and intrinsic and extrinsic attributes. Although some quadrants contain more than one factor, each factor maps onto one of the typology's quadrants. The items included in each factor are described below along with the quadrant in the proposed success typology that they represent.

**F1: organizational performance** includes employee relations, customer relations and image, product or service quality, employee productivity, organizational profitability, and investor relations (extrinsic — professional).

**F2: workplace culture** includes supportive work culture, reputation of organization, competent colleagues, professional autonomy, and employment flexibility (intrinsic — professional).

---

<sup>7</sup> The corporate and small business surveys differ in several ways. The corporate survey included success criteria related to “employment flexibility”, “working with competent people”, “supportive workplace culture”, “financial security”, and “opportunities to participate in community activities”. The small business survey included questions related to “firm profitability”, “product or service quality”, “market acceptance” and “operating performance”.

<sup>8</sup> The 4-factor solution did not precisely map the proposed success typology. Two factors appear to measure extrinsic professional criteria (F1 reflects aspects of organizational performance and F4 reflects financial rewards). Factor 3 reflects rewarding work and captures intrinsic professional criteria. The final factor (F2) reflects both extrinsic and intrinsic personal criteria (see Table 2).

F3: **balanced life** includes personal relationships, managing work/life demands, intellectual activities, dependent care/parenting, and spiritual well-being (intrinsic — personal).

F4: **financial rewards** include income, employee benefits, and stability of income (extrinsic — professional).

F5: **community impact** includes environmental impact, professional recognition (“e.g., industry reputation, respect”), and creating employment (extrinsic — professional).

F6: **personal well-being** includes personal health and being active in the community (extrinsic — personal).

To test for gender differences on the six factors, scales comprised of mean importance scores for the items loading highest on each factor were utilized.<sup>9</sup> T-tests on the mean values of the six scales were conducted to examine potential gender differences in the importance accorded to each. The results suggested no significant gender differences in the importance of organizational performance, community impact, personal well-being or financial rewards. There were, however, significant gender differences for two factors. Women placed greater importance than men on rewarding work (mean = 4.31 versus 4.19,  $p = .005$ ) and a balanced life (mean = 3.95 versus 3.80,  $p = .004$ ). Thus the findings suggest that women place a higher value than men on personal success criteria (intrinsic) but not extrinsic personal criteria. Interestingly, both of the factors which women rated as more important than men reflect intrinsic criteria – in both the personal and professional domains.

## **Discussion and Conclusions**

The above results indicate that multiple success criteria are important to small business owners and corporate managers. Both personal and professional and both extrinsic and intrinsic criteria were rated as highly important. A comparison of the small business and corporate factor solutions is informative. Four of the factors described in both samples groups (personal

fulfillment/personal well-being; balance/balanced life; financial outcomes/financial rewards; and market acceptance/organizational performance) appear to be similar in structure. These factors are also consistent with the conceptual model illustrated in Figure 1. Between the two samples, only one factor, *workplace culture*, was significantly different. This factor includes success criteria of supportive work culture, reputation of organization, competent colleagues, professional autonomy and employment flexibility. The factor speaks to the benefits of being employed in a large organization that affords employment flexibility and opportunities to work with many individuals. As such, the success criteria that load on this particular factor are generally not applicable to most small businesses, given the majority of respondents in this survey (68 percent) employ less than 5 employees. The next step in the research is to examine the relative importance of this factor, particularly among those managers and executives that are considering leaving their employer for self-employment or business ownership. Also, the findings regarding organizational performance are interesting. While research on entrepreneurs has found that the entrepreneur's evaluation of his or her success is related to firm performance (Lee-Gosselin & Grise, 1990; Ray and Trupin, 1989), research on corporate managers has not previously identified organizational performance as important criteria of success. The data also indicates that overall success, for both male and female managers, is strongly influenced by financial rewards. Finally, the research found some gender differences in perceived success. Female managers were more likely than male managers to value intrinsic criteria in both the personal and professional realms. Women business owners accord higher values (than men) to success criteria associated with personal fulfillment and balance. Important questions remain to be examined. It is not clear about the influence on perceptions on business owners' growth

---

<sup>9</sup> Several of the Cronbach's alphas were below .7. This reflects, in part, the small number of items in two of the scales. These low reliabilities may attenuate results.

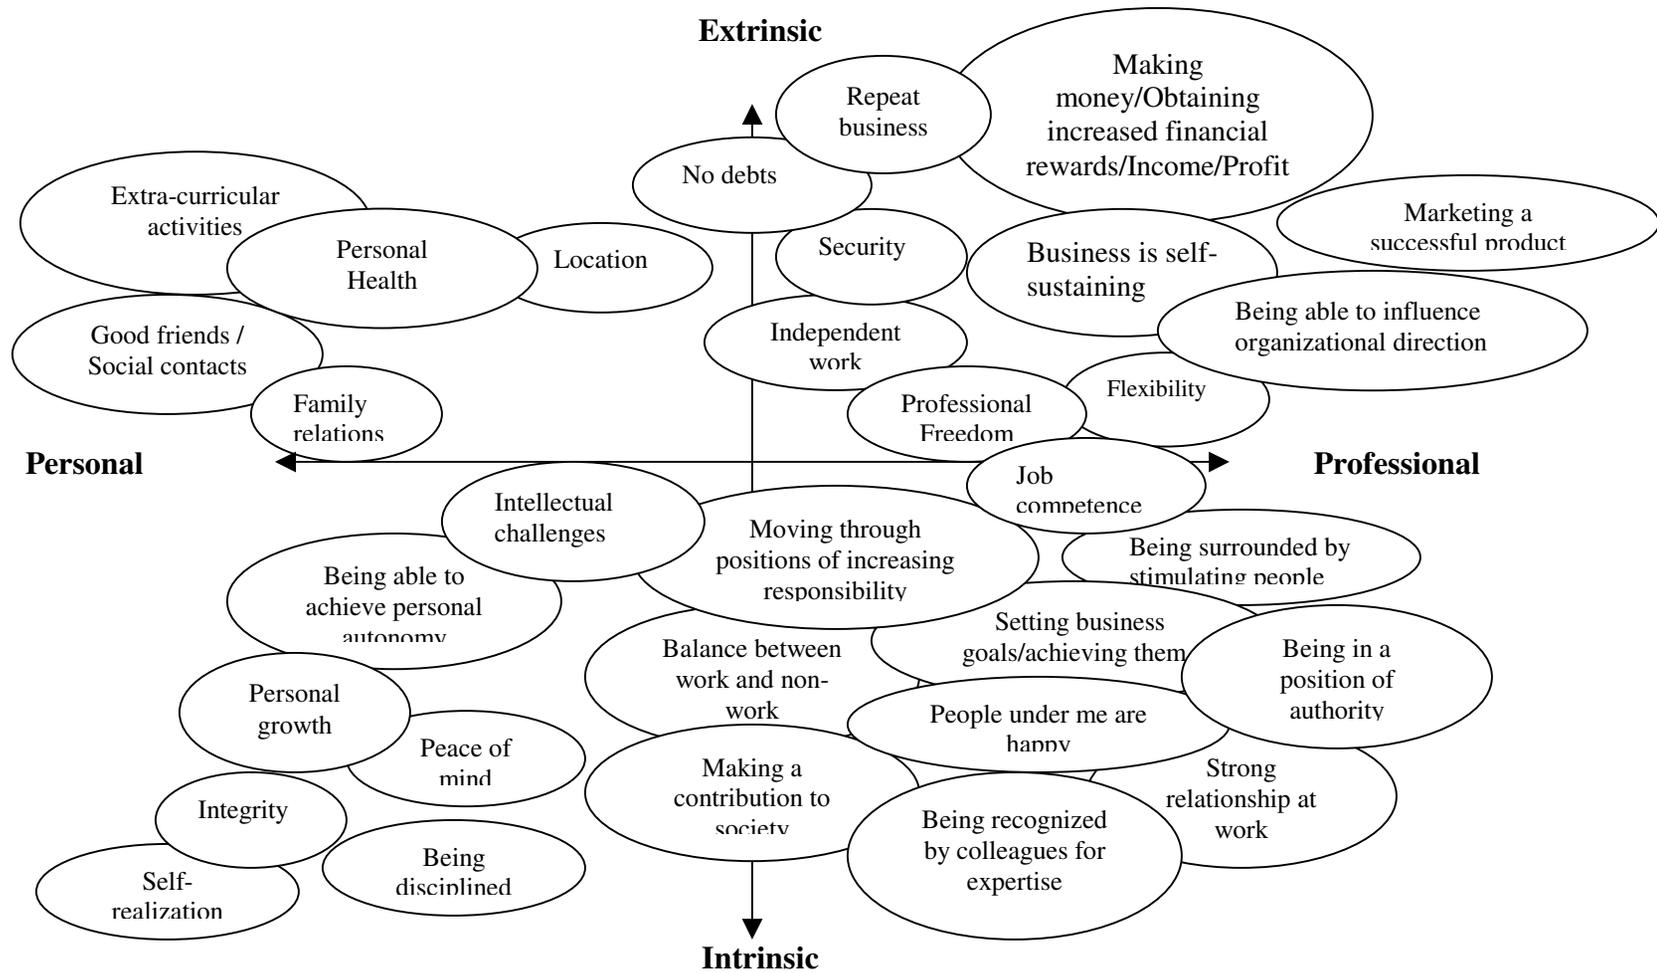

intentions and corporate managers' career aspirations. Work also remains to examine potential differences in perceived success across other personal attributes (e.g., age and business aspirations) and professional attributes (e.g., size and stage of firm, level within the organization). Finally, the research calls for further examination of the underlying structures of the factor solutions. As such, confirmatory factor analysis will be undertaken to further investigate the structure of the factor solutions between the male and female, small business owners and corporate managers. The next phase of the research will examine these associations.

## ABSTRACT

The purpose of the study is to recognise and describe university graduates' individual paths towards entrepreneurship. The focus is on individual's personal demographics and work history and their association with entrepreneurship. Our findings suggest that there are contingencies and distinct factors that have made or may make entrepreneurship an option to be considered regarding one's career and that various combinations of these factors form individual paths towards entrepreneurship. From personal demographics relevant are, in order of importance, age, type of education, number of degrees, gender and role models. Work history, however, outweighs personal demographics in significance. Several aspects emerge, which all are related to entrepreneurship: amount of working experience, variety of work, type of employment, quality and amount of work tasks, career advancement, experience on small firms and labor market status.

## INTRODUCTION

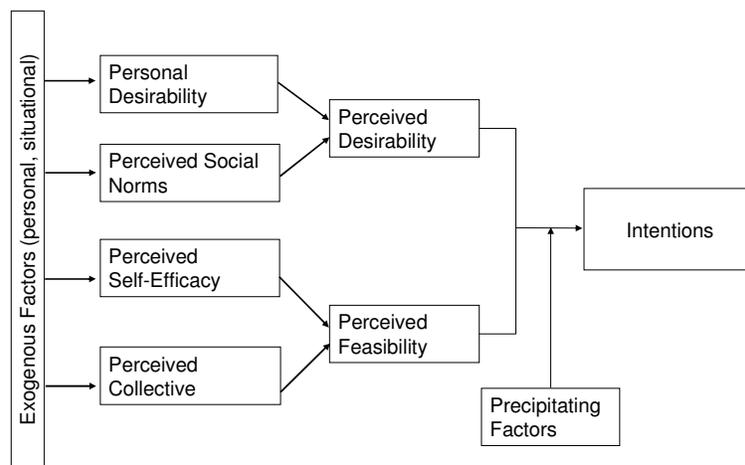

University graduates have traditionally not favored entrepreneurship as a career option. More obvious choices have been public sector tenure or managerial careers in large companies. Both public sector cutbacks, and the transformation of large companies into leaner, meaner machines with fewer layers, have diminished the attractiveness and significance of these paths to those with university degrees. Trends towards outsourcing, and also offshoring – moving facilities to lower cost countries – are increasing the amount of academic applicants in the job market. Entrepreneurship has been presented as one possible substitute career option. At present, of those with a university degree and employed outside the home, less than a tenth work as entrepreneurs in Finland. Conversely, of those with only obligatory basic level education, one fifth is self-employed. (Statistics Finland 2004) Entrepreneurial activity has long been seen to correlate inversely with level of education in Finland. Finnish university degree holders are less active in entrepreneurship terms than Europeans on average. In a recent survey of ten European countries Finland shared seventh place along with Sweden (3 % of respondents defined as entrepreneurs) leaving behind only France and Norway, whereas Italy and Germany scored best with a 10 % and 16 % entrepreneur share respectively (Kivinen – Nurmi – Kanervo 2002). From the economical or public policy makers point of view the advancement of entrepreneurship among academically educated is seen to be of particular interest, as it has been stated that highest potential for growth and survival is among entrepreneurs with university level degree (Arenius et al 2001; Arenius – Autio 2000; Ristimäki 1998).

The study sheds light on transfer from salaried employment towards entrepreneurship among academically educated individuals. It aims at analysing certain exogenous factors and their association with entrepreneurship. First, we examine personal demographics and their role in becoming an entrepreneur. Work history is then analysed to find out whether it differentiates between entrepreneurs and other academically educated people in paid work. Finally, we try to explore how these pieces of work history constitute individual paths toward entrepreneurship.

### ENTREPRENEURIAL INTENTIONS – SOME THEORETICAL INSIGHTS

The theoretical background of the study lies in the assumption that becoming an entrepreneur is intentional, planned behavior. Within the entrepreneurship domain of research the implicit idea originates from Shapero’s and Sokol’s (1982) model of entrepreneurial events, which has been revised by different researchers (for example Bird 1988; Boyd – Vozikis 1994). Another important theory in this respect is Ajzen’s (1991) social psychology based theory of planned behavior. These two approaches have been paralleled by Krueger and others (2000) and Krueger (2000), who has introduced yet another revised model of entrepreneurial intentions. Also Dyer (1994), in building a theory of entrepreneurial careers, has suggested in his model that there are a number of antecedents influencing career choice. They are labeled as individual, social and economic factors.

This study does not try to test those theories but rather builds on them, particularly the one introduced by Krueger (2000). According to this model, entrepreneurial intentions are based on an individual’s perceptions on different exogenous variables, which can further be divided into personal and situational factors (Figure 1). Exogenous variables can affect four types of perceptions related to entrepreneurship as a possible career choice: personal desirability of the event, social desirability (norms), self-efficacy and collective efficacy (see Krueger 2000).

**Figure 1 Intentions model (Krueger 2000)**

In this study, we concentrate only on certain exogenous factors. In addition, we focus on examining whether these variables are in association with entrepreneurship or not, thus the mechanisms of how they may affect on one’s perceptions, intentions and, finally, action are excluded from the study at this point. Moreover, we use the exogenous attributes as building blocks for different paths towards entrepreneurship. For this, exogenous variables have been divided into two groups, personal demographics and career history, which are further divided into a number of subgroups. The study is grounded in data, in a sense that the different

possible dependencies or paths have not been hypothesized in advance, but rather will be based on the results of the data analysis.

In earlier studies it has been noted that from personal demographics male and younger people tend to involve in or consider entrepreneurship as a career option more often than others. These findings have been rather unanimous across different countries (GEM 2005; European Commission 2004). As to the educational level it has been reported that there are country-specific variations in entrepreneurial activity (GEM 2005). In Finland education has a negative impact, i.e. the higher the education the lower is entrepreneurial activity (Statistics Finland 2004). At general (EU-)level, however, the differences may be rather low (European Commission 2004). In particular case of academically educated individuals, it has been discovered that the following attributes are related to entrepreneurs: male gender, older age and early personal interaction with entrepreneur family members (Korvela – Mäki 2002; Harju et al. 2004). The line (business, engineering, etc.) of education also plays a role. It has been found that entrepreneurial activity is higher among those faculties, which are – in a traditional way – providing, in effect, professional or vocational training (e.g. medicine and law) (Tonttila 2001).

Concerning the career history, the total number of years in paid work (Statistics Finland 2004; Harju et al. 2004) and the diversity of working experience (Hyytinen – Ilmakunnas 2004) as hypothesized by Lazear (2002) are related to entrepreneurial intentions in general. In addition, unemployment has been attached to entrepreneurship (GEM 2005) and this applies also in case of academically educated (Statistics Finland 2004). Earlier studies have also concluded that there may not be any association between wage level and entrepreneurial aspirations. On the other hand, unpaid over time has been reported to have a positive impact on these aspirations. (Hyytinen – Ilmakunnas 2004)

## **STUDY DESIGN**

### **Data Collection**

The study is based on literature review, analysis of statistics on entrepreneurial activity and a survey conducted among academics. The research population was defined as employees and entrepreneurs with academic background in either business economics or engineering. The sampling frame included the central, professional organizations for graduates in the aforementioned two fields. We used two types of sampling methods: total sample in case of entrepreneurs and stratified sampling for employees. The latter was based on four strata according to graduation decade, i.e. 1970's, 1980's, 1990's and 2000's.

The survey was conducted among approximately 4.000 academically educated employees and approximately 1.000 entrepreneurs. The data was gathered via email and Internet in February and March in 2005. We sent to each respondent an e-mail invitation with a link to a questionnaire. We worked jointly with the central corresponding member organizations and got a list of their members with an e-mail address. Entrepreneurs and employees were separated beforehand and both groups received respective questionnaires. The response rate was approximately 30 % among employees and approximately 35 % among entrepreneurs.

### **Measure development and data analysis**

As discussed earlier, individual paths towards entrepreneurship are examined here through two building blocks: personal demographics, education and career history. We operationalized *personal demographics* as: gender, age and social role models in terms of entrepreneurial parents or close friends as well as educational background i.e. business economics or engineering, and number of various degrees.

Career history, in turn, was first divided into seven topics based on typical categorizations used in career literature (see e.g. Haapakorpi 1994; Kivinen et al. 2002; Suutari 2002) and then a set of measures were designed to each of them. We measured the *amount of working experience* as total number of years in paid work. We decided to measure *variety of work* in terms of total number of employers, experience of different organization types (private, public government, public community and third sector, e.g. foundations and associations), work history in different industry types (seven categories ranging from manufacturing to services) and total number of employments in different industries.

The *type of employment* was operationalised into employment continuity (temporary or ongoing) and work-time (full-time or part-time). We chose the following items for measuring individual's *work tasks*: type and total number of different tasks (seven categories from secretarial to international tasks), experience in project work (yes/no), overtime work (none/compensated/non-compensated) and, finally, work tasks equivalence to one's education (subjective opinion in 1–5 scale). To capture *career advancement*, we measured different position types during one's work history (manager, expert, official, other), superior experience (yes/no) and salary (at the time of survey or immediately before entrepreneurship). *Experience on small firms* were measured in terms of organization size (four size categories), working in one's family-owned business (yes/no/no such business in family) and possible minority partnership in a (other than stock exchange) company (yes/no). Finally, we measured individual's *labor market status* at the time of survey or immediately before entrepreneurship in terms of ongoing or temporary paid work, full-time studying, unemployed and family or other leave.

For analyzing the data, we decided to use SPSS's binary logistic regression. Entrepreneurs were encoded into one group (value=1) and employees to another (value=0). In addition, we decided to exclude the part time-entrepreneurs from the analysis. This was due to the questionnaire design, which did not allow us to unambiguously measure the career history in paid work *before* becoming a part-time entrepreneur.

## **RESULTS / PATHS TOWARDS ENTREPRENEURSHIP**

The purpose of the study was to recognize and describe academically educated people's individual paths towards entrepreneurship. In the analysis we concentrated first on personal demographics and then on career history in paid work.

The results of the stepwise logistic regression indicate that personal demographics separate entrepreneurs from employees (also) in case of academically educated individuals. All of the examined measures played a role, while the highest prediction power was associated with age. However, the relationship was not linear. The likelihood for becoming an entrepreneur increases up to 45 years of age and declines after that. Entrepreneurial activity seems to be especially low among senior workers. The reasons behind this curvilinear relationship may lie in starting a family and lacking of work experience in one end and forthcoming retirement in the other end of the career path. The second most important demographic feature was found to

be the type of education. Odd ratio is three to one in favor of entrepreneurship if you have a degree in business management in comparison to engineering. Moreover, entrepreneurs possess more often multiple degrees than those in paid work. Gender (male) is also rather important, but comes only fifth in order. Finally, the results suggest that entrepreneurial role models are a pull factor towards entrepreneurship. The example of close friends is almost as important as that of parents. (Table 1)

**Table 1 Logistic regression on significance of individual's demographics in becoming an entrepreneur**

Next, we carried out a stepwise logistic regression on career history and its significance in becoming an entrepreneur. The results are introduced in the table below, including information on the model summary. The model is statistically significant and suggests that the relation between previous work experience and entrepreneurship is rather strong. It can be argued that if all the events, which are presented in the model, have occurred in one's career history there is approximately 50 % chance of one becoming an entrepreneur (see Nagelkerke's R square). The results indicate that all of the examined seven aspects of career history are of relevance for academically educated individuals. The amount of working experience is in curvilinear association to entrepreneurship, odds ratio being highest between 11 and 20 years of paid work. The finding is quite similar to that of age and entrepreneurship, discussed earlier. The natural interpretation is that at the age of 40 (plus/minus 5 years) one has already a certain number of years of paid work behind during which s/he has acquired skills and knowledge needed in running an own business and yet, there are many more years left before retirement.

The variety of work is significant in terms of the industry in a sense that becoming an entrepreneur is more probable for those academically educated who have been working in service sector. There are several possible explanations for this one industry standing out. The capital requirement for establishing one's own business is rather low in contrast to many other sectors, which reduces the financial risks. It may also be that while working in a service sector it is easier to discern a possible business idea than in some other branches. In addition, there may be good chances in service sector to be able to learn useful customer service skills or to establish potential customer contacts. Taken all these issues together, in services the threshold for discovering and realizing potential business ideas may be lower than elsewhere.

| N=1012; Model Sig. < 0,001; Nagelkerke R Square = 0,512; Hosmer and Lemeshow Test, Sig. > 0,05 |                |             |
| <b>Method of Analysis:</b>   |                |             |
| Binary Logistic Regression: Forward Wald   |                |             |

Type of employment is present in the model both in terms of continuity and work time. Contrary to expectations, perhaps, it seems that temporary and part-time work decrease probability of entrepreneurship. The possible reasoning is manifold: a person who has experienced such employment(s) may long for security, which s/he considers is easier to reach through paid work, or one's skills and know-how may not accumulate in atypical employments as effectively as in others. Also personal financial situation for investing to one's own business may be weaker if there are many periods of for example part-time work in the career. Or it simply may be that the type of employment is not an effect at all but a cause of a life style choice, for example a decision to concentrate on family care and work only part-time or temporarily.

Yet another aspect of career history that has significance in relation to entrepreneurship is work tasks (type, quality and amount). Probability of becoming an entrepreneur is highest among those academically educated, who have been working in sales and marketing during their career. Straightforward interpretation is that in this type of work tasks one will automatically learn beneficiary social skills and may also get access to potential customer contacts, learn to understand market demand and customer preferences and may thus recognize business opportunities perhaps easier than those in other tasks. Also, it could be that marketing tasks and entrepreneurial activity require similar characteristics, for example optimism or propensity to act. From this point of view, marketing tasks are not a prerequisite

or stepping stone for entrepreneurship, but a parallel act. Another issue, equivalence of work tasks to one's education, also stands out from the analysis. Again here, as in case of the type of employment, the association is negative in that inappropriate tasks decrease odds ratio for entrepreneurship. This, in a way, surprising finding suggests that know-how and skills needed in academic entrepreneurship accumulate only in work tasks, which quality corresponds the type and level of education. Concerning the amount of work tasks, overtime work is in association with entrepreneurial activity. If you have been working overtime, odds ratio is 5 to 1 in favor of entrepreneurship for compensated working and 12 to 1 in case of non-compensation. The direction appears to be reasonable: one may start thinking that instead of doing extra hours for some else, even without compensation, there might be higher chances for better earnings when working on one's own account. Transition to entrepreneurship can also be easier in a sense that the two may become alike in one's perception as to the length of work days i.e. paid work begins to be suggestive of entrepreneurship or at least the image of entrepreneurship. Concerning the project tasks, they do not seem to be in association with entrepreneurship. It may be that working in projects is so elementary to nearly every academic task that it alone does not differentiate between entrepreneurs and others. Or perhaps the question set up was a bit too loose, since we asked whether one has been involved in project type of work during her/his career. The situation might be different if we had concentrated specifically on project management tasks or on participating projects from beginning to the end and not allowing one to report other type project involvement. Fortunately, we are able to get back to this and narrow the definition in later analysis of the data, since we have also asked the respondents to describe in their own words the content of the project tasks in more detail.

From the examined aspects of work history, also career advancement is attached to entrepreneurship. Management and superior experience both increase the probability of being an entrepreneur. The explanation could be that managerial position develops many of the same skills that are also important in managing your own business, e.g. (strategic) planning, organizing, budgeting and understanding the business logic as a whole. Superior experience, in turn, probably enhances partly the same skills and also those of people management and delegation. Income level and being an entrepreneur are inversely related. The better incomes are the more probably one stays in paid work. One way of interpretation is the risk or uncertainty aspect i.e. if you give up above the average level earnings and start your own business, which does not pay off, in a way you loose more than in such case where your earnings are lower. Put it in another way, the better one's incomes are in paid work, the more successful the business (idea) has to be to receive the same financial status as in paid work. Slightly different perspective is to consider incomes as a pull factor towards entrepreneurship. If the main motive in becoming an entrepreneur is potentially high incomes, this factor is of less relevance for those, who already earn rather well in paid work.

Furthermore, our findings suggest that experiences on small firms during the career may be important for academically educated individuals in becoming an entrepreneur. Probability for entrepreneurship is higher for those, who have been working in micro (less than ten employees) or small companies (10–49 employees). The effects of organization size can be diverse: in smaller companies the work tasks may be more versatile than in others thus improving multiple skills, less hierarchical and specialized organization may also allow better chances for understanding the business logic. In addition, working in a small company may dispel prejudices or negative images attached to entrepreneurship, bringing out what is good in it or knowing the entrepreneur personally may act as a positive role model towards establishing an own business.

Finally, the logistic regression model indicates that academically educated individual's present status on the labor market is of importance. Entrepreneurship is more probable for those who are currently unemployed in comparison to those being in ongoing employment. It may, of course, be as a case, where entrepreneurship is foremost a matter of necessity rather than opportunity based act. On the other hand, one could argue the opposite, if we recall what has been discussed in the theoretical chapter above. In Finland as in many other western countries, the level of academic unemployment is rather low, which means that finding a new job is relatively easy. On these grounds, unemployment might be interpreted as a critical event, where there is an opportunity to break the inertia and to fulfill one's own dream of starting a business one day.

So far we have discussed about the different aspects of career history and their possible role in becoming an entrepreneur. We have been able to find out certain dependent variables that seem to increase the odds ratio for entrepreneurship. The question then arouses that are these findings individual paths towards entrepreneurship as indicated in the paper title or are they merely a description of one typical path? Our answer is 'partial yes' to both of these two viewpoints. On one hand, the statistical significances found in the analysis are generalizations and when they all exist in one's career history the entrepreneurial probability is in its highest. On the other hand, all of these dependencies rarely exist together. In the data there was only one entrepreneur who had undergone all but one of them. Thus, in our opinion each of the examined issues are pieces of career paths, and there are altogether 12 of these pieces or sub-paths, which can be combined in a numerous ways thus making each path somewhat unique. The individuality is present both in number and type of career path pieces. For some individuals there may be only two or three events that have occurred in their career in paid work before establishing own business while in some other cases s/he has undergone eight or nine of these 'entrepreneurially predictive' career sub-paths. Yet, there are other individuals with also eight or nine milestones behind them and they are still in paid work. This is introduced in the table below (Table 3).

**Table 3 Number of critical pieces of career paths, which increase the probability of being an entrepreneur**

| <b>Number of critical pieces of career paths</b> | <b>Share of entrepreneurs</b> | <b>Share of employees</b> |
|--|-------------------------------|---------------------------|
| Less than 3                                      | 3,8 %                         | 8,4 %                     |
| 3-4  | 6,6 %                         | 28,5 %                    |
| 5-6  | 29,1 %                        | 35,9 %                    |
| 7-8  | 46,0 %                        | 25,1 %                    |
| 9-10   | 14,2 %                        | 1,9 %                     |
| 11-12  | 0,3 %                         | 0,1 %                     |
| Total  | 100 % (n= 880)                | 100 % (n=289)             |

Thus, we do not believe that the career history is solely affecting the entrepreneurial choice, although we have been examining the topic in isolation from some other theoretically important insights. Also, different steps are important to different individuals. For one, working in a small company may be that crucial one piece in career path, while for the other this is not important or not enough, but needs to be combined with the managerial experience, before entrepreneurial intentions realize. Yet for someone else, other pieces of career path, like working in service sector, are critical from the point of view of entrepreneurship.

## DISCUSSION

The aim of the study was to examine and describe individual paths towards entrepreneurship among academically educated. We decided to focus on exogenous factors, specifically personal demographics and previous work history and their association with entrepreneurship as a career choice. The study was exploratory in nature, thus no preliminary hypothesis or proposition were set in advance.

To begin with, our findings suggest that personal demographics differentiate between entrepreneurs and others also among academically educated individuals. Significant factors are, in order of importance, age, type of education, number of degrees, gender and role models. The probability for entrepreneurship is highest if you are 36–45 years, have educational background in business administration, possess multiple degrees and are male with entrepreneurial parents and close friends. These demographics draw a picture of qualified, vital entrepreneurs indicating that entrepreneurship is not considered as a necessity in lack of other choices or a cooling of period among academically educated.

There is also a rather strong association between career history and entrepreneurship according to our data, suggesting that by understanding previous work experience we can learn a great deal of entrepreneurship. All of the examined aspects seem to be relevant in case of academically educated individuals. Typically they end up choosing entrepreneurship as a career choice after being in paid work for more than 10 but less than 20 years. The variety of work is significant in that those who have been working in service sector establish their own business more often than others. Atypical (temporary or part-time) employments, in turn, seem to decrease the probability of entrepreneurship. Also type, quality and amount of work tasks are of relevance. Experience in sales and marketing, equivalence between work and education and over-time work all increase likelihood for entrepreneurship. As to the career advancement, experience of managerial position and superior role both act in favor of entrepreneurship, whereas higher salary levels have the opposite linkage. Work experience in a small company during career also associates positively with the choice of entrepreneurship as does the present labor market status in terms of unemployment.

We are also suggesting that each of the above-mentioned elements of career history can be seen as a piece of path toward entrepreneurship. Different types or number of pieces exist or are relevant for each academically educated, thus there are numerous combinations of these pieces making every path unique. Some of the paths are probably more common than others, an issue of clustering which we will probably get back to later on in analyzing the data. Also, these elements of work history do not exist only among those who have chosen entrepreneurship, but also among those who are (still) in paid work. This indicates that work history does not solely determine one's path toward entrepreneurship. Instead, it seems to matter to some extent, but there are also many other important antecedents of intentions such as personal values and various situational factors (see e.g. Shapero 1982).

At this point, we would also like to discuss briefly about the impression of academically educated individuals' entrepreneurship, which comes across by examining their work history. Firstly, our interpretation is that, opportunity based entrepreneurship is emphasized instead of necessity among academically educated in Finnish context. Neither is entrepreneurship considered as some kind of casual work or hobby, but a serious career choice, which is heavily based on skills and know-how gained in paid work. Furthermore, the findings indicate

that the threshold towards entrepreneurship becomes lower, when there are features in paid work that are typically attached to entrepreneurship, such as longer working hours, multiple as well as managerial skills and experience in sales and marketing and customer service. Also, it seems that academic, all-around education does not provide for or individual's does not perceive it providing for enough skills and know-how to establish an own business soon after graduation. Instead, a number of years in paid work are considered necessary in order to gather more human, social and financial capital needed in entrepreneurship. Moreover, it shows that academically educated are often not interested in starting their own business unless they are pretty sure that there is enough grounds for successful execution of it. On the other hand, it could be argued that it is not always a matter of capability shortage as such, but newly graduated individuals may not recognize, how their university qualification can be turned into a profitable business idea. An implication for the public policy could be that it is possible to promote entrepreneurship by familiarizing individuals earlier, while still studying, with entrepreneurship and in this manner raise it to same level with other employment forms as a career choice. In practice this could mean, for example, that at university level, teaching methods would be organized in such a manner that they develop more entrepreneurial way of thinking. Education could also be organized so that it would give a more comprehensive idea of business logic, instead of teaching only narrow and separate aspects of it. Also, small business owners could be utilized in educational cases as speakers etc. in order to offer role models of how to turn academic know-how into business idea.

Finally, our analysis arouses at least as many new research questions as it has been able to answer so far. To capture a more thorough picture of the phenomenon, the examination should probably be enlarged to cover also other types of academic education in addition to business administration and engineering presented here. It would also be useful to compare the role of work history in becoming an entrepreneur between academically educated and those with other educational level. Also individual paths or pieces of such paths need to be studied further, since certain combinations or clusters are probably more common than others. Moreover, it would be of interest to make cross-national comparisons in order to examine, whether there are any national features or peculiarities between work history and the choice of entrepreneurship. In addition, it would probably be valuable to explore whether the work history is in association not only with the choice of entrepreneurship, but also with the success/growth or failure. Foremost, it would be of great importance to explore more thoroughly the mechanisms through which the work history and individual intentions and actions toward entrepreneurship converge – an issue, also we will try to shed some more light in further study of the data by analyzing how work history affects individuals' perceptions of desirability and feasibility (see Krueger et al. 2000) of executing entrepreneurial career.

Abstract

Do people have to be wealthy to become entrepreneurs? I reexamine the effect of initial wealth on the propensity to participate in a business start-up. Previous studies address this question using self-employment data. Self-employment surveys, however, treat respondents as either self-employed or wage workers and thus provide a poor measure of firm creation. In contrast, a recent survey of the establishment of new businesses reports that 50 percent of entrepreneurs engage in full-time and 20 percent in part-time wage and salary work. In this study, I develop a model of entrepreneurial choice where individuals can both hold outside paid jobs and be involved in start-ups. To evaluate wealth effects, I use a new data set that follows both entrepreneurs and start-ups. I instrument wealth with month-to-month changes in S&P and find that wealth does not affect the propensity to become an entrepreneur. Start-up owners devote a portion of their outside wage income to investments in their firms. Thus, wealth becomes less relevant for starting new businesses. This result suggests that people do not have to be wealthy before they can start a business.

Extended Abstract Paper

New businesses often rely on individual and household wealth as a source of start-up capital, financial security, or insurance for acquiring funds (Gartner et al. 2004). This seems to suggest that assets have a crucial effect on the level of entrepreneurial activity; but the literature offers mixed evidence. The seminal studies of Evans and Jovanovic (1989) and Dunn and Holtz-Eakin (1994) argue that entrepreneurs are liquidity constrained, and that wealthy people, who are better able to obtain substantial amounts of initial capital, are more likely to be involved in entrepreneurial activities. In a recent paper, however, Hurst and Lusardi (2004) show that wealth effects are significant only for the top 5 percent of the wealth distribution. In this paper, I reexamine the effect of wealth on the tendency to participate in a business start-up and argue that initial wealth does not significantly affect the propensity to become an entrepreneur.

The existing literature suffers from two major problems. First, previous studies address the question of wealth effects using self-employment data. Self-employment surveys, however, treat respondents as either self-employed or wage workers and thus provide a poor measure of firm creation. In contrast, a recent cross-national study on the level of entrepreneurial activity of

40 countries (Global Entrepreneurship Monitor, GEM, 2003 Executive Report) has established that 80 percent of those who implement a start-up also hold outside jobs. Thus, to answer the question of wealth effects, we need to use data that reflects the complexity of entrepreneurial activity.

The second major problem in the existing literature is that wealth is likely to be endogenous: what helps people become wealthy might actually be the same quality responsible for their unobservable entrepreneurial talent. Hence, one has to correct for this potential endogeneity. Blanchflower and Oswald (1990), Holtz-Eakin et al. (1994), and Hurst and Lusardi (2004) recognize this problem and propose a set of instrumental variables; however, the literature still does not seem to agree on whether wealth engenders self-employment. To deal with this problem, I instrument wealth with month-to-month changes in Standard & Poor, a source of assets variation that is exogenous to entrepreneurial decisions.

In this study, I propose a part-time entrepreneurship model, where new business owners can hold outside paid jobs. Start-up owners devote a portion of the outside wage income to investments in their firms. Individuals who spend relatively more time in outside jobs have more wage income, and respectively more savings and capital to invest in a start-up. Therefore, the opportunity cost of time spent in a start-up is not just the outside wage, but also the potential savings and investments that come with this wage. Thus, entrepreneurs will continue spending time in their new business until what could be produced for one more hour in the start-up is equal to the outside hourly wage plus the savings that this wage would have brought.

To evaluate wealth effects, I use a new data set that allows me to confront the two major problems discussed above. The Panel Study of Entrepreneurial Dynamics (PSED) is an extensive nationally representative survey of the establishment of new businesses that follows both entrepreneurs and start-ups. The PSED covers business creation from a start-up to the full development of an operating firm. The survey reports that 50 percent of entrepreneurs have full-time work and 20 percent have part-time wage and salary work outside the start-ups.

The PSED provides several innovations over previous empirical research. The data were specifically created to follow both nascent entrepreneurs and start-ups. Nascent entrepreneurs are selected based on three criteria: being involved in a start-up for the past 12 months, expecting to be at least partial owners of the business, and functioning in a gestation phase of the business. The third criterion determines whether "the start-up has a positive cash-flow that covers expenses and the owner-manager salaries for more than three months." Respondents with a positive cash-flow for more than three months are excluded. Start-ups are followed for a period of four years. In this way we can observe the effect of wealth and initial capital on the start-ups' performance and the rate of entrepreneurial survival.

I instrument wealth with month-to-month changes in S&P and find that wealth does not affect the propensity to become an entrepreneur and that people who already have jobs are more likely to become involved in entrepreneurial activities. Start-up owners devote a portion of their outside wage income to investments in their firms. Thus, wealth is shown to be not significantly relevant for starting new businesses. This result suggests that people do not have to be wealthy before they can start a business.

## **ABSTRACT**

This paper discusses the conclusions of some research projects undertaken at the University of Economics in Prague, aimed at the measurement of performance of SME. The aim of the initial project was to test some recommended methods and models and its practicality for SME. For this purpose, a small sample of just two companies was chosen. It has revealed that even companies certified according to ISO EN have the weakest point in marketing expertise and strategy creation.

The next stage started with the formulation of a new hypothesis. Which factors should be included in the evaluation of the future successfulness of a firm? How to define the development potential? To answer these questions, a much larger sample has been analyzed. Fifty companies were analyzed according to six components- strategy and planning, marketing, production processes and technology, quality and environment, logistics and human resource management. Several statistical methods were used to analyze the interdependencies between the main group factors and the six remaining determinants. The conclusions of the self assessment approach were used by placing the companies into four groups A, B, AB, and C, which express the development potential.

In the third stage the same questionnaire was used to examine 95 SMEs (heterogeneous group). The conclusions have proven that more than 50 % of companies do not have any mission and corresponding strategy. More than 30% do not perform marketing activities and do not practice CRM. Almost 50% of the sample companies' produce using licenses or by copying products. Only 50% of companies make use of their own R&D for the product innovations. Just 28 % underwent certification processes, 70% do not create integrated supply chains and logistic and almost 50% of companies do not have their MIS integrated. Motivational systems are not innovatively created.

## **INTRODUCTION**

The business environment can be characterized by permanent and quick changes. These changes are caused by increased global competition, increased intensity of changes in technology and better communication networks using the Internet. These factors influence the activities of all kinds of firms. But there are special problems that affect SMEs more than larger businesses:

- they have more difficult access to capital and conclusively they can't invest in technological advancement
- they have weaker position in acquiring state contracts
- they don't have enough financial means to have top experts on their payrolls
- the system approach to a product development is not generally practised
- they have to compete very often with dumping prices of multinational corporations

- they do not possess enough expertise to follow and interpret the impact of a steady inflow of new laws, regulations and prescriptions which create a difficult business environment in the Czech Republic. (They often have to hire a specialized consulting agency in order to obtain funding from the EU, because of complexities of the application procedure).

Regardless of these barriers, SMEs represent a formidable economic force, creating 37 % GDP of the CR and providing employment for 60% of the labour force. Some selected indicators can be seen from the (Table 1.)

*Table 1 here*

The critical role of managers consists in **continuous** assessment of the firms performance aimed at seeking steady improvement – **potential development**. Standard procedures of performance assessment, which have been used in the past, do not reflect new entrepreneurship approaches. The most frequent questions that address the evaluation of company's performance of contemporary management are the following: [1].

- **How well is the main company's process organized?**
- **How well is the innovation process managed and what is the position of the company's product, compared to the product trend? Does the company set the trend? Or is it falling behind?**
- **How good is the company's financial performance? Can it stand to the benchmarked values? Is the shareholders value increasing?**
- **How well does it stand in the eye of the customer? Does it satisfy the customer's needs?**

- **How intensive and well defined is its corporate social responsibility?**

The traditional methods of rating the company's performance have concentrated on measuring the benefits of cash inflows rather than providing an answer to the above mentioned questions. The professionals have reacted with the development and proposal of new models such as the **Balanced Scorecard** [2], and also proposing the European model of **EFQM - European Foundation for Quality Management** [3] and have therefore created a new paradigm for the measurement of performance. See - Figure 1 [4].

*Figure 1 here*

The faculty at the University of Economics in Prague have been considering this paradigm as a great challenge and have been working on the implementation of these new models for a considerable period of time. The research work follows a traditional financial analysis track and contemporary approaches (BSC, EFQM) with the aim of supplying the managers (especially those of SMEs) with effective methods for measuring performance and giving them the tools for future strategic decisions.

First of all, the research hypothesis has been formulated:

**“WHICH FACTORS SHOULD BE INCLUDED IN THE EVALUATION OF FUTURE SUCCESSFULNESS OF THE SME-HOW TO DEFINE THE DEVELOPMENT POTENTIAL OF A FIRM”?**

Shall we proceed according to BSC or EFQM model, or shall we develop our own model? The decision in favour of EFQM was partly influenced by the prospective entry of the Czech Republic into the EU and by expected support and subsidies for SME.

## **THE FIRST EXPERIMENTAL RESEARCH [5], USING EFQM - SMALL SAMPLE**

For the first pilot study project the EFQM model was used and a sample of two companies was acquired for implementation. The short description of the EFQM:

1. **Leadership (100 points)** - mission, ethical code of behaviour, delegation of authority, structure, relationship with customers, performance appraisal.
2. **Policies & Strategy (90 points)** – how the strategy was implemented. The overall work for supporting the information system. Effectiveness of market research and its use for market prognosis and consumer behaviour. Internal reporting system and its organization.
3. **Human Resources (90 points)** – planning, recruiting and skills development of employees.
4. **Partnership & Resources (90 points)** - partnership with suppliers and community. Effective use of financial resources, financial strategy, investment in technology, R&D.
5. **Processes (140 points)** - how well are the main processes organized? The detailed description of processes, parameterization of processes and its outputs. ISO 9001. Services and customers.
6. **Customer Satisfaction (200 points)** - quality, safety and reliability of a firm's product, customer loyalty, CRM.
7. **Results Concerning Employees (90 points)** - motivation and transparent options for promotion. Performance appraisal of individual's effort. Working environment
8. **Results Concerning Social Responsibility (60 points)** - *image* in the public, corporate social responsibility, environmental protection.
9. **Performance and Results ( 150 points )** - summarization of key results covering:

- Financial performance i.e., cash flow, liquidity, EPS, sales, revenues, net profit,
- Intangibles, expertise, knowledge - based progress etc.

### **TARGET COMPANY: AXIS LTD.**

Axis Ltd. is a company well established on the Czech market, belonging to the SME group, producing a broad spectrum of steel products - production of steel constructions, technological facilities, high pressure pots, reconstruction of machinery equipment, assembly of gas equipment, machine tool shaping etc.

The company was subject to a certification process in 1999 according to ISO 9001 norm, and gained the corresponding certificate. This research study has made use of a standardized questionnaire of EFQM, recommended by National Centre for Quality. The questionnaire consisted of fifty questions which were to be answered using a self assessment procedure. The answers had to follow four grade evaluations:

- A. Fully accomplished - excellent process or result, fully implemented.
- B. Considerable progress- giving enough space for improvement.
- C. Moderate progress - needs further research. Bringing good results if implemented.
- D. There are no measurable results. There are some good ideas which were not seriously reviewed or practiced.

The self assessment process has been implemented at the top and middle management levels of the company. The results of the overall evaluation can be seen on figures 2 and 3.

*Figure 2 here*

*Figure 3 here*

### **Conclusions:**

Managers of AXIS have to direct their attention to the improvement of customer satisfaction or to implement a system of CRM. The next recommendation would be to pay more attention to create a clear and effective strategy concerning main firm processes.

### **DEVELOPMENT POTENTIAL OF A COMPANY [6]**

In our paper, we define development potential as a set of tangible and intangible factors directly influencing contemporary and the future success of a company. Development potential in our interpretation is a vector of six components describing basic areas of a company's activities. Within each component, six characteristics follow. The model has been originally developed at the University of West Bohemia in the U-SME innovation project, supported by the Leonardo da Vinci programme of the EU [7]. It uses the following components:

- **Strategy and Planning:** strategic control system, mission and vision of a company. Awareness and sharing a vision by employees.
- **Marketing:** marketing costs can be today as high as 50% of total expenses. It is traditionally the weakest point of many Czech companies. The following factors were subject to analysis: market research, market positioning, competitor's analysis, and advertising.
- **Production Processes and Technology:** does the company follow its competitors or does it set up a trend? Is there an internal innovation centre, or does the firm make use of licences? How is the innovation process organized? How is the technological

development and its applications in products and production processes implemented?  
Although innovation is a central issue discussed in connection with the development potential, innovation itself is not a goal, but only a tool in achieving company goals.

- **Quality and Environment:** these are assessed in relation to EN ISO standards. Quality goals are measurable and consistent with the quality strategy. From a microeconomic point of view, the environment is treated as a public good or negative externality.
- **Logistics:** (Supply Chain Management) - complete system of planning, organising, realising and controlling the flow of goods. The role of outsourcing and its impact on lowering (increasing) costs.
- **Managing Human Resources. Support of MIS for Integration of All Informational Activities i.e.** approaches to information processing and use of internet technologies. Motivational systems, learning processes, company culture and knowledgeable management.

The contents of the components are based on a practice of benchmarking in leading Czech companies. Their structure corresponds to empirical findings published in professional readings.

The definition of the development potential and its measurement is difficult. It is not easy to generalise a procedure assigning it a universal quantitative value. Self-evaluation is once again an important aspect of the process and it reflects the maturity of the company management and its interest in improving their company performance. It follows the structure of the first above mentioned case, using EFQM.

The development potential assessment was performed in three steps. In the first step, the development potential of individual components was evaluated. In the second step, the overall assessment was determined and in the third step the classification of the company was done according to its overall assessment and put into one of the four categories (**C**, **AB**, **B**, **A**).

The classification of companies into the corresponding categories was done according to a set of European Standards – EN ISO 9000:2000, which specifies the rules and system terminologies and on the British norm BS 7000-1:1999, providing a manual for management of development processes and innovations in long time periods. The classifications of companies according to their development potential are shown in the following (Table 2.)

*Table 2 here*

Companies classified as **C** are not ready to implement development activities, to improve their performance and to better satisfy their customers. If they want to develop, they should first implement fundamental changes in their organization and other basic company processes.

Companies classified as **AB** are prepared to complete changes necessary for improving their performance, but must consistently improve their basic processes. Management training can help to achieve long-term goals. Companies classified as **B** can employ and further develop their potential and they are prepared to undergo a certification process according to corresponding ISO standards. Class **A** includes companies with the highest development potential, highly competitive, high performers successful in mid- and long-term horizon.

The definition of development potential and its components was followed by field research using the structured questionnaire. A sample used in the research consisted of fifty companies active in different industries in North Moravia and five companies from the Pilsen region. Field research in North Moravia was performed by the Faculty of Management of Tomáš Baťa University in Zlín in the second quarter of 2002 [7] and it was continued by the collection of data from more companies in both regions. Conclusions presented in this paper are based on data acquired from fifty companies from the following industries:

- 13 - rubber and plastics;
- 20 - machinery;
- 12 - steel and steel product;
- 5 - mechanical engineering;

Nine of these companies were classified as AB, twenty seven as B, fourteen as A. There was no company classified as C. The total average achieved in the four-point scale was 3.06.

The results were processed using one- and multi-dimensional statistical analysis. Financial performance was determined using data published in authorised databases. The following parts of the paper describe conclusions of statistical analyses.

#### Multidimensional regression analysis

In multidimensional regression analysis, the development potential was treated as a dependent variable, while its components were treated as independent variables. The resulting regression model is:

$$DP = - 0.0037 + 0.1809 * \text{Quality and environment}$$

- + 0.1683 \* Logistics
- + 0.1938 \* Marketing
- + 0.1488 \* Information systems and human resources
- + 0.1775 \* Strategy and planning
- + 0.1305 \* Production processes and technology

The analysis results can be interpreted as follows:

- None of the six components could be eliminated from the model.
- The relationship between variables is statistically significant
- The total development potential in the six component model is the most sensitive to the *Marketing* component.
- No correlation coefficient in the model has a value higher than 0.5. Mutual correlation of components was not found.
- Explaining power of the model is 99.5%.
- It is possible to use the following simplified models, which have the following explaining powers:

1 component – 79%

2 components – 89%

3 components – 95%

4 components – 98%

5 components – 99%

- The strategy component significantly influences classification of the development potential into classes.
- For the sample used in this paper it was not necessary to use weighting factors of components.
- The questionnaire has a high explaining power.

### **Conclusions:**

The development potential includes factors which can be influenced by the company owners and managers. They had a considerable effect on the financial performance and correlate with value creation. The relevancy of the selection of the development potential components was demonstrated by statistical methods.

Although **marketing** is the most sensitive factor, its values in our sample were the lowest. It confirms the general experience, that **Czech companies generally have a lack of marketing expertise and do not collect information about customer's behaviour.** (Confirmed also the by conclusions of the AXIS case).

**Production processes and the technologies** components achieve the highest values. For firms in our sample this component is of the highest importance. It was demonstrated that this component provides the best one-component estimate of the total development potential and its correlation with ROE is the strongest. **Companies having leading positions in technology and having high quality products, attract employees and satisfy their customer's needs.**

**Strategy and planning** component significantly influences classification of the companies according to their development potential, but its explaining power is low. It confirms that the **dependence between the performance measurement and the strategy is rather weak.**

Correlation analysis has proven to be a both-sided statistical dependence between the development potential and ROE. It indicates that, when DP is growing, the value of the invested capital by company owners is also growing. It was demonstrated that the company with a higher DP has the potential to satisfy its customers, owners and other stakeholders.

The process of the development potential assessment can be used by the management as a manifold tool in analysing ways that would lead to efficient implementation of the company goals and objectives. Firstly, the two-sided correlation between development potential and financial performance enables the creation of strategic plans aimed at developing all DP components. Secondly, the DP together with selected financial indicators can be a valuable tool in evaluating the company owner's ambitions and shareholders expectations. Its application could be productive also in benchmarking in the present case of a sufficient database for a specific industry.

Finally, we have to stress that; an important precondition for implementation of the DP assessment procedure is the understanding, learning and willingness of companies' management to practise it.

## **THE DEVELOPMENT POTENTIAL OF CZECH SME - ENLARGED SAMPLE.**

Enlarged Sample of SMEs and their characteristics:

The sample consists of 95 SMEs [8], which are described by following characteristics:

**Number of Employees:**

- a) 1 - 9
- b) 10 - 49
- c) 50 - 250
- d) N/A

*Figure 4 here*

**Sales in 2002:**

- a) < 250 mil. Czech crowns
- b) 250 - 1.450 mil
- c) more
- d) N/A

*Figure 5 here*

**SME by Industry:**

- a) Retailing
- b) Services
- c) Building
- d) Machinery
- e) Electronics
- f) Metal industry

- g) Chemical and pharmaceutical
- h) Food and beverages
- i) Agriculture
- j) Power engineering
- k) Wood processing
- l) Textile and clothing industry
- m) Transportation
- n) Insurance
- o) Other
- p) N/A- not filled in ( or performing more different activities )

*Figure 6 here*

**Production Is Aimed at:**

- a) Domestic market
- b) International market
- c) Both
- d) N/A

*Figure 7 here*

**THE EVALUATION OF DEVELOPMENT POTENTIAL OF SME USING THE SAME SIX COMPONENTS AS IN SAMPLE 2.**

In the third stage the same questionnaire was used to examine 95 SMEs (heterogeneous group). The same six characteristics correspond with categories used in the second research study were chosen.

**Mission and Vision, Strategy and Planning:**

- a) The firm concentrates on present situation and day to day activities
- b) The firm possesses written documents about future development for 1 to 2 years
- c) The firm possesses written documents about future development for 3 to 5 years
- d) N/A

*Figure 8 here*

**Marketing Activities:**

- a) Not performed at all
- b) Occasionally – only ( in case) if they are threats to our position
- c) Systematic market positioning

d) N/A

*Figure 9 here*

**Processes and Innovations (described by two characteristics):**

1. Product development

- a) Internal R&D
- b) Licensing
- c) Copying
- d) N/A

*Figure 10 here*

2. The initialization for product change:

- a) No initiative being undertaken
- b) Mainly from internal sources
- c) From external environment
- d) N/A

*Figure 11 here*

**Quality and Corporate Social Responsibility:**

- a) Quality monitoring – not performed systematically
- b) Quality regularly monitored, but analysis of corresponding incurred costs will not be performed
- c) Results of quality monitoring and incurred costs being subject of strict control and evaluation
- d) Firm gained certification and works according to its requirements

*Figure 12 here*

**Supply Chain Management and Logistics:**

- a) Firm keeps a steady and reliable set of suppliers
- b) A supplier will be chosen case by case
- c) Firm developed data base of suppliers with intensive interchange of information
- d) N/A

*Figure 13 here*

**HR and MIS (described by two characteristics):**

1. Motivational factors of employees

- a) The basic duty of an employee is to perform efficiently and obey orders
- b) There exists a sophisticated motivational system for employees
- c) The company management develops ( except of the existence of a structured motivational system ) a distinctive effort for creating a friendly working environment
- d) Team work is broadly practiced

*Figure 14 here*

## 2. Information system:

- a) The formalized and centralized IS does not exist
- b) The formalized IS for operational purposes exists, but does not provide pragmatic information for strategic management
- c) The well structured and integrated IS exists for all levels of management
- d) N/A

*Figure 15 here*

## **Conclusions**

The last phase of research is still taking place, so we can make some preliminary conclusions.

The same questionnaire has been used as in the previous stages as well as the same self

assessment technique, so the conclusions are fully comparable. It gives us a sample of 145 SMEs covering a broad spectrum of companies. The latest evaluation has brought evidence that more than **50%** of the companies do not create any vision and corresponding strategy (though we have proven that the dependence between performance measurement and the strategy is rather weak). More than **30%** do not perform marketing activities and do not practice CRM. Almost **50%** of sample companies produce using licenses or copying products. Only **50%** of companies make use of their own R&D for the products innovations. Just **28%** underwent certification processes, **70%** do not create integrated supply chains and logistic processes and almost **50%** of the companies do not have MIS integrated. The motivational systems are not satisfactorily composed. This set of preliminary conclusions gives us a clear direction of how can we proceed with further research in order to help SME in the Czech Republic to increase its competitiveness within an enlarged EU.

### **CHALLENGES FOR FUTURE RESEARCH:**

- **HOW TO IMPROVE PRODUCT DEVELOPMENT?**

The interviews and research conclusions have proven that the majority of SMEs need to learn a new method for product development.

- **THE PSYCHOLOGICAL FACTORS AND PERSONAL ATTRIBUTES NECESSARY FOR SUCCESSFUL MANAGEMENT OF SME.**

The Czech Business Schools will have to focus on the development of more courses, focused on entrepreneurs.

- **WHAT IS THE EXPERIENCE OF SUCCESSFUL SMEs WITHIN THE MOST DEVELOPED COUNTRIES? IS IT TRANSFERABLE?**

## **ABSTRACT**

Increasing pressures are beginning to be placed on privately-held businesses to meet stringent regulatory requirements of Sarbanes-Oxley (SOX) and Federal Sentencing Guidelines for Organizations (FSGO) regarding board use and ethical compliance processes. We studied 167 family businesses in two states to determine how extensive “best” governance practices were being actually utilized, particularly those related to boards of directors and ethical compliance processes.

Survey analyses indicate very mixed results, although a significant pattern exists, as expected, that larger family businesses were more actively using boards with independent directors, had formal written codes, and utilized more formalized ethical compliance processes. Given the critical importance of not only developing codes but also having effective compliance processes in place, the overall survey results suggest widely varying practices that may not yield desired results and may also expose the family business to unnecessary legal liability. Compliance processes need more active attention and this paper outlines the specific operational elements of effective compliance processes that will improve their application.

## **Introduction**

There are good business and family reasons for codes of ethics, conduct, and values. Codes can help define and preserve the family’s core values across generations (Aronoff and Ward 1996) and help build bottom-line performance when operationally expressed within the business (Aronoff, Astrachan, and Ward 1998; Ferrell, Maignan and Loe 2004; Miller 2002; Moran 2004; Sharma 2004). Continuing corporate scandals have, however, raised the importance of codes and other forms of corporate governance even further, and there is growing evidence that Sarbanes-Oxley (SOX) Section 406 regulations will increasingly be applied to privately-held businesses (Alford 2005; McDonagh 2005; Plant, Pratt, and McCann 2004). Among several provisions that already apply are calls for more independent and knowledgeable boards of directors with formal committees, particularly an audit committee, and formal ethical compliance policies and practices (Lander 2004).

As Alford (2005) and McDonagh (2005) note, there are several reasons why private companies must become more aware and compliant with SOX regulations. Large suppliers, insurance companies, and lenders are, for example, increasingly expressing expectations that their private company customers comply with such practices to get the best terms (Smoot 2004). Large public companies seeking to acquire private companies must also certify that the entire combined company after a deal is compliant with SOX within a limited time period, and any private company seeking to be acquired should have those practices well in place if a timely closure is

desired. Acquirers may be more willing to pay higher premiums for private businesses that demonstrated effective governance practices (Moscetello 1990) and meet SOX requirements. Whether this is the case or not may be an important emerging research question for family business researchers.

Private business owners also recognize that ethical codes and formal corporate governance processes make sound sense for growing businesses, and SOX, while arduous to comply with, provides a well-recognized, universal standard. Adopting such standards becomes important as family businesses move toward greater professionalism in management and systems (Dyer 1989; Flamholtz 1990; Sharma, Chrisman, and Chua 1997).

SOX regulations are relatively new and controversial in terms of their impact, but we have found much less attention given to the 1984 Federal Sentencing Guidelines for Organizations (FSGO). FSGO has been requiring privately-held businesses to develop and implement ethical compliance systems for nearly two decades (Desio 2004; Murphy, Castillo, Sessions, Steer, Hinojosa, Horowitz, O'Neill, Jaso, and Reilly 2003; United States Sentencing Commission 2004). The U. S. Sentencing Commission was created by Congress in 1984 to establish sentencing policies and practices for federal courts, including recommendations of the form and severity of punishment for offenders convicted of federal crimes. The most common offense for which organizations are sentenced under FSGO is fraud, followed by environmental pollution, money laundering, antitrust, and food and drug violations.

Of primary interest to family business owners is that the 1991 organizational sentencing guidelines apply to all organizations – publicly or privately held, corporations or partnerships (LeClair, Ferrell and Fraedrich 1998). In fact, according to research posted on the Sentencing Commission's internet website, 92.7 percent of convicted organizations in 1988, and 88.2 percent in 1989 (the most recent figures based upon ownership) were closely-held organizations – higher by far than publicly-traded organizations (5.8 percent) and non-profit institutions (0.6 percent) (<http://www.usc.gov/training/corpq&a.pdf>).

As Desio (2004) notes, "Criminal liability can attach to an organization whenever an employee of the organization commits an act within the apparent scope of his or her employment, even if the employee acted directly contrary to company policy and instructions." The organization can be fined, placed under probation, ordered to make restitution, and to publicly apologize for the offense.

Two factors that can mitigate the punishment of a company are the existence of an effective ethics program and the business's efforts to self-report the offense and cooperate with the authorities. Fines can be reduced up to 95 percent if the company can show it had an effective ethics and compliance program in place and that the violation was an unusual occurrence in an otherwise ethical business. On the other hand, the absence of an effective ethics program may cause the court to put the organization on probation. The Commission strengthened the criteria for an effective program in 2004 to reflect its experiences with organizations over the past ten years and to align with the Sarbanes-Oxley Act and other governmental initiatives (Desio 2004).

Given the importance accredited to family-supported ethical cultures and governance practices, we have found few recent large surveys of family businesses about their actual governance practices, including their operational use of ethical and behavioral codes (Gallo 2004; Hornsby, Kuratko, Naffziger, LaFollette, and Hodgetts 1994; McCann, Leon-Guerrero, and Haley 2001). It is not clear how family businesses are actually engaging in “best” governance practices such as the use of formal boards of directors, regular board meetings, use of outside directors, and formally developed and applied codes (Aronoff, Astrachan and Ward 2002; Sharma 2004). While advocated, do such prescriptions match the reality of family business in today’s increasingly stringent regulatory context?

## **SURVEY DESIGN & METHODOLOGY**

To explore these questions, two family business centers in Florida and Washington State surveyed 1497 family businesses in their states which yielded a usable sample of 167 family owned and managed businesses for an 11.2 percent overall response rate. Two closely-timed waves of requests for responses were made to yield this sample. These family businesses had been identified through several years of various contacts due to the two centers’ programs and periodic surveys. Respondents were identified as either the founder or the current leader of the business. Respondents were asked to complete a written survey to explore three broad research questions:

- What is the current state of practice regarding the development and application of codes of ethics, conduct, and values?
- Have these practices been influenced by SOX and FSGO requirements?
- Are other governance practices also associated with the use of codes, specifically regarding the use of boards of directors?

The survey contained 19 mixed scale questions. Categorical and scaled questions asked about the existence of a formal board of directors, current number of independent non-family board members, and whether the board meets regularly. Two open-ended questions encouraged respondents to list specific written or unwritten ethical values or beliefs that were important to their businesses and to relate specific instances where their codes had been operationally applied. Participants were invited to attach a copy of their own company’s codes of ethics if desired. Sixteen respondents did return documents such as mission/vision statements, guidelines, codes, or policy handbooks. Finally, we asked to what extent they had made changes in their business in response to SOX and FSGO. The full survey is in Appendix 1.

Demographic variables included the age of the business, number of employees, ownership and management structure, revenues, number of generations actively involved, and the primary nature of the business to test whether there were significant demographic relationships with ethical and board practices (See Table 1). Two-thirds of the sample was Washington State family businesses, but no significant demographic differences were found between states. Over one-half of the total sample had more than 25 employees and over five million dollars in annual revenues, 60 percent were over 25 years old, and 90 percent were family owned and privately held. 80 percent had two or more generations involved, and the sample represented a broad array of industries.

-- Insert Table 1 Here --

## **ANALYSES & RESULTS**

Summary statistics were first developed for all items and content analyses performed on the open-ended responses to identify patterns and themes among the values/beliefs listed, and among the situations or instances where codes had been operationally applied. We were particularly interested in the characteristics of those family businesses that were most likely to adopt board and code practices. It would be reasonable to hypothesize that larger, more established family businesses were most likely to have adopted such practices, and this relationship was tested.

Table 2 provides a descriptive summary of the overall responses obtained. The following results can be summarized:

- 57 percent had formal boards of directors with 63 percent of those with boards holding regularly scheduled meetings.
- 69 percent had no independent directors, and only 22 percent had two or more independent directors.
- 54 percent had written codes with 59 percent of those with codes having them apply to both the family and the business.
- 40 percent of those with codes had them written by the founder or family leader alone, and 39 percent had help from outside professionals.
- 94 percent of those without written codes still believe that there are clearly understood and accepted unwritten ethical values and behavior standards in their organizations.
- In terms of their code's application, 27 percent are only verbally communicated, 25 percent are communicated both verbally and in writing, 12 percent are expressed in formal policy/procedure manuals, and 34 percent are introduced in training programs and employee orientations.
- Importantly, only six percent were aware of or had changed their codes and their use in response to FSGO, and only two percent in response to SOX.

-- Insert Table 2 Here --

### **Boards, Codes and Demographic Relationships**

Standard parametric statistical analyses appropriate for mixed scale and categorical response data were then performed (Pearson correlations, ANOVA tests). Tables 3 and 4 summarize some of the statistically significant relationships among the variables that were found.

-- Insert Tables 3 & 4 Here --

As readily expected, there were significant correlations between gross revenues and: (a) business age, with older businesses having greater revenues; (b) type of ownership structure, where smaller revenue businesses were most associated with a family owned and managed structure; and (c) the number of generations active in the business, with predominantly first generation firms having smaller gross revenues. While some additional relationships among the demographic variables were suggestive, none were statistically significant.

Notably few significant relationships between the use of a formal board of directors and the demographic variables were found. The presence of a formal board and size of the business in terms of both number of employees and in terms of gross revenues were positively correlated ( $p \leq .01$  respectively). No other significant relationships were found between the presence of a formal board and business age, ownership/management structure, and number of generations involved. This finding suggests that at least in this sample the utilization or relative lack of utilization, of formal boards and associated practices effectively spans the gamut of firms.

### **The Use of Written and Unwritten Codes**

We found no significant correlation between the presence of a written code and business age, size in terms of employees, or number of generations. Business revenues and written codes were positively correlated ( $p \leq .05$ ). With this single exception, codes, like boards, were generally either absent or present across a broad array of businesses in this sample. There was a strong but not significant correlation between whether a family business had a written code of ethics and whether it also had a formal board of directors ( $p \leq .12$ ). However, there was a significant relationship between whether a business had a code of ethics and whether its board meets regularly ( $p \leq 0.01$ ) and the number of independent directors on the board ( $p \leq .05$ ). While the lack of a significant correlation between written code and board presence is intriguing, the associated board practices of meeting regularly and having independent directors suggests a strong positive relationship among governance practices, at least for larger family businesses.

As noted in Table 2, a surprising 40 percent of respondents reported that they developed their written codes by themselves, and 39 percent had used an outside professional to help them. Only 11 percent reported their spouse, a previous generation, or “other” person had developed their code. The founders or leaders apparently take it upon themselves to initiate and deliver at least a draft for consideration by the family, but the data clearly suggests that code development is not a widely-participative or collaborative task. We could not determine what type of professionals were involved from the survey data, but several conversations with family businesses close to the two centers conducting the research indicate that process consultants and lawyers have tended to be most widely used.

When no written code existed, as was the case for 46 percent of the sample, we asked whether there were specific ethical values or expectations regarding family member or employee behavior that were still understood and accepted. Ninety-four percent responded that they did believe they had specific unwritten ethical values and expectations that were understood and accepted. Table 5 summarizes in rank order the major values or beliefs provided as examples. Even when codes are not formally expressed, family business owners assume their values are known in the family and business.

-- Insert Table 5 Here --

### **Code Compliance Practices**

When asked how their codes were communicated, 27 percent reported that they were verbally communicated, 25 percent said they were communicated both verbally and in writing, 12 percent

have them formally written, and 34 percent formally expressed their written codes in employee training and/or orientation sessions. We used this variable as a measure of how highly developed compliance practices were among sample businesses. Sample businesses were viewed as increasingly compliant as their codes became less verbally communicated and more formally communicated in writing with their actual application in training and orientation classes for employees.

We found significant correlations between the two board practices – regular meetings and number of independent directors – and formalized code communication ( $p \leq .05$  and  $p \leq .01$  respectively). In addition, code communication and business size in terms of number of employees and gross revenues were both strongly correlated (both  $p \leq .01$ ). There was a clear pattern of the larger family businesses adopting code compliance practices that would objectively be considered acceptable to regulators.

Respondents were also asked if there were important opportunities or situations where they have relied on, referred to, or directly used their ethics and values codes, whether written or unwritten. While 38 percent chose not to answer this “yes” or “no” question, of those that did, more than 97 percent answered that they had done so in a variety of situations, most related to regulating specific types of employee behavior.

From an ethics compliance process perspective, it is interesting that over a quarter of respondents only verbally communicated their codes, yet 97 percent operationally used them. How much consensus there is across employees about the exact nature and meaning of those codes would be interesting to explore, since low consensus could obviously create undesirable outcomes when employees were held to those standards. In addition, verbally communicated codes do not meet the regulatory expectations set in either SOX or FSGO.

Finally, it was even more interesting that responses clearly indicated that only very small percentages of family businesses had responded to either SOX or FSGO regulations – only two percent and six percent of all those in the sample respectively. These results are actually not surprising given the very early stage of development of these regulatory trends toward private sector application.

## **SURVEY IMPLICATIONS**

Several important issues are raised by these results. In many respects, the results are initially disconcerting. We would have hoped, for example, that larger numbers of family businesses would have adopted such widely advocated governance practices as the use of written codes and formal boards of directors that met regularly and had at least some degree of independence. Family business researchers, consultants, and professionals have been calling for the adoption of such governance practices for years (Robinson 1982; Schwartz and Barnes 1991).

While these practices are generally found most frequently within the larger family businesses in this study, the overall use percentages -- 57 percent for formal boards and 54 percent for written codes -- indicate an undesirable level of utilization across the entire spectrum of sample businesses. This could be seen as a question of whether the glass is half empty or half full, since

these are still relatively large percentages. However, the increasingly stringent regulatory environment facing private businesses suggests a need for much more intensified work by family business leaders and the professionals serving them to meet these rapidly evolving expectations.

Nor does the presence of such practices actually say anything about their actual effectiveness in use. We did not try to directly assess ethical practices effectiveness, although past research regarding several such family business practices, including the use of boards, has indicated a positive relationship with competitive performance (e.g., McCann, Leon-Guerrero, and Haley 2001). We know from this research that significant percentages of family businesses are utilizing boards, although their independence is in question, judging from the limited number of independent directors utilized. There are a number of useful resources, including books and articles, about how to construct and manage effective boards of directors for family businesses (Aronoff and Ward 1996; Ward 1992; Ward and Handy 1988).

### **Creating Effective Compliance Processes – the Missing Element**

Many of the governance practices revealed in this research would not satisfy the growing demands of the regulatory and business stakeholders expecting well-defined and executed compliance practices. The family businesses in this study have developed codes and applied them in a variety of forms within a variety of situations. While many of them are utilizing effective compliance methods judging from the way they are communicating their codes, the larger pattern reveals uneven use in terms of their explicitness and the ways they are communicated and applied.

The widely varying practices revealed in this study mean that a significant percentage of family businesses may be criticized for unprofessional governance practices, finding them selves paying higher costs for insurance or accessing capital. At an extreme, it may mean being unnecessarily exposed to legal liability in cases covered by regulations. There are, of course, also the very important cultural reasons why codes are important to family businesses, as noted at the opening of this paper.

We found numerous references about how family businesses can professionalize their practices (Dyer 1989; Flamholtz 1990), but little in the family business literature about the compliance process or implementation stage of family business codes. For example, one of the most widely referenced resources on writing a code is that by Aronoff, Astrachan, and Ward (1998). While these authors very effectively focus on the code development stage, they leave off without focusing on the equally important implementation stage in which compliance process issues are addressed. Compliance processes need more active attention, and the specific elements of effective compliance processes consistent with both SOX and FSGO guidelines are described in Table 6 and Table 7.

-- Insert Tables 6 & 7 Here --

For the smaller family business these guidelines can represent formidable obstacles; a tremendous amount of time, effort, and even expense could be involved in assuring an effective compliance process. Smaller businesses will and, judging from the relatively high percentages

without codes in this study, have made trade-offs of benefits against implementation costs. The family businesses with written codes which are already communicating them in training and orientation sessions very likely appreciate the importance of codes for their impact on their business cultures and work practices, and there is now the added benefit of being much better prepared for regulatory reasons. As business scholars and professionals, we must continue to stress such practices at every opportunity when working with family businesses. Our work is far from complete in this regard.

**ANOVA Relationships with “How Code is Communicated”**

| <b>Variable</b>                        | <b>F</b> | <b>Significance</b> |
|--|----------|---------------------|
| 1. Business has Written Code           | 54.133   | .000                |
| 2. Code Applies to                     | 3.743    | .027                |
| 4. Presence of Formal Board            | 3.900    | .051                |
| 5. No. of Independent Directors        | 2.680    | .014                |
| 6. Board Meets Regularly               | 3.917    | .051                |
| 7. No. of Full-time Employees          | 2.600    | .038                |
| 8. 2003 Gross Revenues                 | 2.150    | .078                |
| 9. Business Age                        | .650     | .630                |
| 10. No. of Family Generations Involved | .530     | .663                |
| 11. Ownership Structure                | .680     | .568                |

**Table 5**  
**Major Values/Beliefs of Importance to Family and Business**

| <b>Rank Order of Values/Beliefs Listed</b>                         | <b>Number of Times Cited</b> |
|--|------------------------------|
| Honesty  | 60                           |
| Respect for others   | 40                           |
| Interpersonal behavior attributes (how one gets along with others) | 31                           |
| Integrity  | 31                           |
| Fair   | 27                           |
| Customer focus   | 24                           |
| Employee focus   | 20                           |
| Quality/excellence in product/service                              | 18                           |
| Don't lie, cheat, or steal   | 18                           |
| Golden Rule  | 14                           |
| Work ethic   | 13                           |
| Family focus   | 11                           |
| High ethical standards   | 10                           |
| Community service  | 9                            |
| Professionalism  | 7                            |
| Family sets example  | 7                            |
| Language standards (no profanity, etc.)                            | 6                            |

**Table 6**  
**Seven Elements of an Effective Compliance System**

1. Establish policies, plus procedures to achieve them (written codes, etc.).
2. Assign specific high-level person to be responsible and accountable for them.
3. Use care in delegating authority to appropriate person of high integrity.
4. Communicate them through training programs, publications, etc.
5. Utilize monitoring and auditing systems to detect illegal conduct and encourage reporting of criminal activity (audits, hotlines, etc.).
6. Consistently and quickly enforce the standards through discipline of offenders.
7. Respond quickly to offenses – take steps to prevent further similar offenses and modify the codes and policies as necessary.

**Table 7**  
**Practical Advice for Implementation and Compliance**

1. Don't Just Print, Post and Pray:
  - Thoughtful and effective codes provide guidance for making ethical business decisions.
  - Must be actual living documents encouraged and valued at the highest levels.
  - High-level executives need to model behavior and not tolerate exceptions.
  - Publicly restate code and publish it every year in the annual report.
2. Have a committee of independent non-executive directors on the Board who are responsible for code compliance
3. Staff training – at least annually
4. Evaluate ethics procedures
5. Establish “hot line” or “help line” for employees seeking guidance or facing unethical conduct
6. Publicly commit to being an ethical organization:
  - Be open about ethical standards and conduct
  - Post vision, values and codes of conduct on Web site for public viewing
  - All company board members, legal and accounting firms should sign the code and pledge support
7. Managing by Walking Around (MBWA) is good way for managers and supervisors to clearly and consistently communicate their ethical expectations and requirements.
8. Let employees know how they are doing regarding supporting the organization's mission, vision and ethical goals.
9. Build ethical conduct into the firm's systems -- Provide employees and customers with a written code of ethics and values
10. Share how the code applies to particular cases and actions Measure success – simple systems to measure the effectiveness of ethics initiative
11. Determine if employees are living the code -- reward those who do, remove those who don't
12. Keep the lines of communication open:
  - Ask questions to identify pitfalls before they occur.
  - Communicate openly and honestly.
  - Talk with employees at all levels...often!

## Appendix 1

# 2004 Survey of Ethics, Conduct and Values in Florida Family Businesses

The Florida Family Business Program at The University of Tampa invites you to participate in this survey of ethics, conduct, and values in family businesses. Please respond by June 25, 2004. For your convenience, a prepaid, addressed envelope is enclosed. If you choose, please attach any written codes of ethics, conduct, and values you believe may be of value in this research. If you have any questions or comments, please contact Wendy Plant at 813-253-6221, ext. 3782 or wplant@ut.edu. Thank you!

---

1. Do you consider your firm to be a family business?  Yes.  No.  
If no, please stop here and return the survey. Thank you for participating.
2. Does your family business have a written code of ethics, conduct or values statement?  Yes.  No.  
If no, please skip to question # 5.
3. If yes, is the written code of ethics, conduct, or values statement meant to apply to:  
 Family only.  Business only.  Both family and business.
4. If yes, who developed the written code of ethics, conduct, or values statement? Check the one(s) that best applies.
  - a.  Developed by myself
  - b.  Developed with spouse
  - c.  Developed with parents and/or children
  - d.  Developed by previous generation
  - e.  Developed with help of outside professionals (accountant, lawyer, consultant)
5. If you do not have a written code or statement, are there specific ethical values or expectations regarding family member or employee behavior that you still believe to be clearly understood and accepted?  
 Yes.  No
6. Whether or not you have written statements, please list below some of the unwritten ethical values, conduct, or expectations that you think are most important and valuable to your family and business?  

---

---

---
7. How have you communicated these ethical, conduct, and values expectations, whether written or unwritten, to employees and other family members not involved in their development?
  - a.  Do not have
  - b.  Only verbally communicated
  - c.  Both verbally communicated and written (e.g., vision mission statements)
  - d.  Formally expressed in writing (e.g., policy/procedures manuals)
  - e.  Both formally expressed and introduced in areas such as training programs and orientations

8. Are there important opportunities or situations where you have relied upon, referred to, or directly used your ethics and values, whether formal or unwritten? If yes, please provide a brief example (or attach additional pages):
- 
- 
- 
9. Have you become aware of and changed your code of ethics due to requirements in the *Federal Sentencing Guidelines for Organizations*? \_\_\_\_\_ Yes. \_\_\_\_\_ No.
10. Have you changed your code of ethics due to the *Sarbanes Oxley Act*? \_\_\_\_\_ Yes. \_\_\_\_\_ No.
11. Do you have a formal board of directors? \_\_\_\_\_ Yes. \_\_\_\_\_ No.  
If no, please skip to #14.
12. How many independent non-family members are on the board of directors? \_\_\_\_\_
13. Does the board meet regularly? \_\_\_\_\_ Yes. \_\_\_\_\_ No.
14. Approximately how many full-time employees are in your firm?
- |                           |                                  |
|---------------------------|----------------------------------|
| a. _____ 0 - 25 employees | d. _____ 101-250 employees       |
| b. _____ 26-50 employees  | e. _____ more than 250 employees |
| c. _____ 51-100 employees |                                  |
15. What were your 2003 gross revenues? (As with all data, this is confidential.)
- |                            |                             |
|----------------------------|-----------------------------|
| a. _____ Below \$5 million | d. _____ \$50-\$100 million |
| b. _____ \$5-\$10 million  | e. _____ Over \$100 million |
| c. _____ \$10-\$50 million |                             |
16. How recently was your family business established?
- |                                 |                                 |
|---------------------------------|---------------------------------|
| a. _____ Less than 10 years ago | d. _____ 50-75 years ago        |
| b. _____ 11-25 years ago        | e. _____ More than 75 years ago |
| c. _____ 26-50 years ago        |                                 |
17. How would you best characterize your family business ownership and management?
- |  |
|--|
| a. _____ Family owned and managed  |
| b. _____ Family owned and non-family managed                                 |
| c. _____ A combination of family and other ownership, and family managed     |
| d. _____ A combination of family and other ownership, and non-family managed |
| e. _____ Family managed but not owned by the family                          |
18. How many family generations are actively involved in the business at present? \_\_\_\_\_
19. What is the primary nature of your business?
- Retail
  - Manufacturing
  - Transportation/Distribution
  - Engineering
  - Construction
  - Agricultural Production
  - Tourism/Entertainment
  - Restaurant Industry
  - Professional Services
  - Technology/Communications
  - Health Care Services

# THE ROLE OF INTELLECTUAL CAPITAL IN OPPORTUNITY RECOGNITION OF ENTREPRENEURS

## Abstract

The study hypothesizes that intellectual capital of entrepreneurs enhances their opportunity recognition. The study investigated the population of metal- and ICT-ventures established in 1998 in three regions of Finland. The results of the study illustrated, first, that knowledge acquisition in opportunity recognition requires formal knowledge of a particular domain. Second, the results revealed that formal knowledge increases competitive scanning in opportunity recognition. Third, the results indicated that proactive searching in opportunity recognition is enhanced by prior management experiences, intrinsic motivation, and creativity of entrepreneurs. Fourth, innovative behavior in opportunity recognition needs strong intrinsic motivation, since it is internal, mental playing with ideas. In addition, management experience decreases innovative behavior. Last, management experience hindered collective action in opportunity recognition.

## 1. Introduction

Entrepreneurship has been defined at least as ownership of firms (Cuevas 1994), management of small businesses (Scott and Bruce 1987), innovativeness (Schumpeter 1934), networking (Larson and Starr 1993), organizing (Johannisson 1988), and making ideas work although the needed resources are not controlled (Stevenson and Jarillo 1990). One of the central definitions is presented by Kirzner (1979, 1981, 1997), who claims that entrepreneurship is about alertly recognizing and exploiting opportunities. Entrepreneurship is then a process of creating new businesses, in which an opportunity is recognized and then turned into a form in which it creates economic value by using own and others' resources and personal relations (see Bygrave and Hofer 1991; Gartner, Bird and Starr 1992; Christensen, Madsen and Peterson 1994; Muzyka, de Koning and Churchill 1997). Several recent studies have proposed that the focus of academic interest in entrepreneurship should be specifically in studying op-

portunity recognition and realization (e.g. Shane and Venkataraman 2000; Sarasvathy 2001; Dew, Velamuri and Venkataraman 2003; Davidsson 2003).

Shane and Venkataraman (2000) have argued that opportunity recognition is about creating new means-ends relationships between goods, services, raw materials, and organizing methods. Sarasvathy (2001) has put forward that in opportunity recognition is merely question of creating imaginatively various possible end-results based on given means. Thus, if opportunity recognition is seen as an artifact of problem solving, so the artifact is not possible to logically deduce because the “information space” is so complex that the best possible decision is impossible to “calculate” (see Mayer 1992). Opportunity recognition is like creating a game at the same time that you are playing it (as children’s games many times are) instead of trying to play the familiar game more efficiently (see Sarasvathy 2001). Thus, an opportunity is not an end-result of a logical process but merely a conglomeration of fragments that will have to be made sense of while the situation is developing. This implies that opportunity recognition is about creating a sketch or a rough illustration of the way a business is going to be created (see also Vesper 1991).

Based on the studies of opportunity recognition it is possible to see that certain intellectual capabilities characterize those entrepreneurs who are able to recognize opportunities (Christensen et al. 1994; Hills 1995; de Koning and Muzyka 1996; Hills and Shrader 1998; Erikson 2002; Baron and Ensley 2003; Davidsson and Honig 2003; Sternberg 2003; Ucbasaran, Westhead and Wright 2003). These entrepreneurs have experience-based skills in the domain where they work, their formal knowledge of the area is often high, they have previous entrepreneurial/managerial experience, their intrinsic motivation pulls them to seek opportunities, and they are able to creatively question the present business situation. Like Davidsson and Honig (2003) have argued entrepreneurs involve their intellectual capital in opportunity recognition in order to be able to create imaginary end-results, i.e. opportunities (see also Sarasvathy 2001).

The research on opportunity recognition is still in its infancy (Chandler, DeTienne and Lyon 2003) although it has been seen as one of the main activities involved in entrepreneurship (Gaglio and Katz 2001). Especially empirical studies are needed to develop the knowledge of the phenomenon (see Davidsson 2003). On the other hand, opportunity recognition is often seen as one-dimensional concept, although recent studies have shown that it consists of several distinct lines of behavior (Davidsson and Honig 2003; Delmar and Shane 2004). This has caused that we do not know how intellectual capital affects the different dimensions, i.e. different behaviors involved in opportunity recognition. In addition, intellectual capital has been often seen in opportunity recognition consisting of only domain knowledge, formal knowledge, and entrepreneurial/management experience (e.g. Davidsson and Honig 2003). Present study proposes that this is too narrow view and it neglects recent developments in the research on intellectual capital specifically. Sveiby (1998) and Rastogi (2000), for example, stress that the concept should besides knowledge include also motivation and creativity because these have been noticed to be important vehicles of processing the knowledge. Based on the above argumentation, the study examines how intellectual capital of entrepreneurs affects their different behaviors involved in opportunity recognition. This study proceeds so that it is presented first the theoretical background, second hypotheses, third the used methodology, fourth the results, and last conclusions of the study.

## **2. Theoretical Background of the Study**

Becker (1975) in his seminal study on human capital suggested that human capital strongly affects quality of behavior in business life. He defined human capital as consisting of experience-based and formal knowledge. Gimeno, Folta, Cooper and Woo (1997) widened this to embrace entrepreneurs as well. Sveiby (1998) and Rastogi (2000) changed the term and used instead of human capital the term intellectual capital because it more clearly shows that it is a question of cognitive, learned (and learn-

able) capabilities. Sveiby (1998) and Rastogi (2000) also pointed out that motivation and creativity should be parts of the concept because cognitive human information processing consists of besides knowledge storing also knowledge aiming and knowledge interpreting and re-interpreting.

Cooper (1981) stressed the importance of knowledge of the domain to be one of the main factors affecting opportunity recognition. The domain-specific experience is important in order to be able to alertly scan the market and find gaps that could be filled (see Kirzner 1979). Without the domain knowledge it is very difficult to interpret the information cues in the industry because the information processing of entrepreneurs is tied to existing knowledge structures, e.g. domain knowledge (Manimala 1992; Shane and Venkataraman 2000). Former experiences and knowledge of the area are required to see opportunities that others do not recognize (Kaish and Gilad 1991). The domain knowledge is needed to scan relevant information, give it appropriate meaning, and make good judgments based on it. Human beings do not just perceive information, interpret it, and act based on it as rationally as possible but are guided by the knowledge they already have acquired in their processes of perceiving, interpreting, and acting (e.g. Woo, Folta and Cooper 1992; de Koning and Muzyka 1996). Thus, less experienced entrepreneurs might miss relevant information, understand poorly what they perceive, and make decisions and actions that are unwise.

Cooper (1981) was the first to suggest that formal knowledge would help to use domain specific experience. Formal knowledge creates knowledge structures that do not have to be learned by trial and error but by education and training. It is suggested here that formal education and training are needed because this type of more general knowledge gives capabilities to examine issues in their entity. Experience-based knowledge as the only knowledge type could cause entrepreneurs to have a narrow view, which could sometimes be even dangerous because it might create biases and errors in thinking of entrepreneurs (Baron 1997, 1998; Zietsma 1999).

This is also argued by Shane and Venkataraman (2000), who proposed that two factors influence opportunity recognition: (1) the information an entrepreneur possesses, and (2) his/her cognitive capabilities. Here it is proposed that these are developed by the interaction of formal knowledge and domain knowledge. The importance of formal knowledge in the creation of excellence is clearly verified in the studies of expert problem solving (see Mayer 1992). First, every individual has a certain stock of information, and this information has an impact on behavior of a person, and also on opportunity recognition (Shane and Venkataraman 2000). Furthermore, such prior information is stored as mental schema to our minds, and these are like "road-maps" guiding our thinking, behaving, and discovering. This information we possess could be knowledge of cheap raw material, the latest research results of digital communication, values of customers, etc. Second, every individual processes information differently. Some are able to connect many kinds of old and new pieces of information into a new value-adding opportunity. What is here suggested is that this second ability is mostly in the form of formal knowledge and achieved through formal education.

The study done by Muzyka, Birley and Leleux. (1996) revealed that in venture creation investors appreciate leadership potential of the lead entrepreneur and the management team, industry experience, and track record of the leading entrepreneur and the management team. Birley, Muzyka and Hay (1999) indicated that investors trust management competencies of a leading entrepreneur and a team to hold in any investment opportunity. Furthermore, the authors stress that the leader capabilities of an entrepreneur are important to investors, i.e., the skills to build a team, inspire others, manage the winds of change, and think strategically of the whole business situation. Thus, it could be seen that entrepreneurial management skills are important in opportunity recognition.

Intrinsic motivation is in many studies seen to be an important inspiring factor in opportunity recognition. Cooper (1981) stressed that motivation makes skills, knowledge, and perceptions work together so that they are made use of in opportunity search. Without intrinsic motivation it could happen

that, although entrepreneurs were experienced and their expertise was high, success make them satisfied with the situation (Kaish and Gilad 1991). Thus, despite being skilled they are not any more internally motivated to search for opportunities. Sigrist (1999) claimed that an entrepreneur's own personal line is crucial. By this she means that subjective principles, ideas, and style of an entrepreneur lead him/her to create a unique kind of a venture. This underlines the importance of intrinsic motivation in the form of a personal way to do things. She also found that inner strength is needed in order to achieve goals because often entrepreneurs do not get enough social support. Thus, an entrepreneur must have a very strong intrinsic need to search for an opportunity and confidence to go on even though some might advise him/her not to. The above argues the motivational aspects to be powerful in opportunity recognition.

Gilad (1984) was the first to suggest opportunity recognition to happen due to creativity of entrepreneurs. His point of view is based on Kirzner's (see e.g. 1979) idea that entrepreneurs are more alert to opportunities in the market than others. Gilad (1984) sees that others than entrepreneurs overlook possibilities to establish a new business. The ability to discover inconsistencies by linking information cues requires creativity. Creativity in his case could be understood as seeing of links between many types of information and finding a solution that does not exist yet. Thus, creativity in opportunity recognition is not about routinely searching for the best solution from solutions that already exist – *"it is non programmable, non standardized, and unpredictable insight about the true nature of reality"* (Gilad 1984).

### 3. Hypotheses of the Study

#### **Hypotheses 1a–1e: Effects of Intellectual Capital of Entrepreneurs on Knowledge Acquisition in Opportunity Recognition**

Woo et al. (1992) indicated that lack of domain knowledge created cognitive barriers preventing the knowledge acquisition (see also Mayer 1992; Baron 1998). Shane and Venkataraman (2000) underlined as well the importance of domain knowledge in order to be able to acquire knowledge. De Koning and Muzyka (1996) studied the behavior of entrepreneurs who had been successful in finding several opportunities. What was illuminating was that entrepreneurs with domain knowledge knew how to acquire knowledge and what kind of knowledge they need. In addition, Hills and Lumpkin (1997) and Hills, Lumpkin and Singh (1997) indicated that entrepreneurs who had domain knowledge of the industry actively seek new knowledge. Gaglio and Taub (1992) showed in their experiment where entrepreneurs were asked to develop opportunities based on the data the researchers gave them that entrepreneurs were not willing to do that because they did not have real domain knowledge of the area. Thus, the following hypothesis is presented: **H1a:** The higher the domain knowledge of entrepreneurs, the more intense is their knowledge acquisition in opportunity recognition.

Cooper (1981) already considered formal knowledge to interact with domain knowledge in knowledge acquisition. Gaglio and Taub (1992) indicated that entrepreneurs used formal skills to make sense of the situation. This is supported by the study by Woo et al. (1992). Bhave (1994) also pointed out that formal knowledge motivates entrepreneurs to search the needed knowledge. Last, Sigrist (1999) illustrated how entrepreneurs used their formal knowledge to manage and control the knowledge acquisition of domain knowledge. This suggests that formal knowledge provides the frames and aim for knowledge acquisition. **H1b:** The higher the formal knowledge of entrepreneurs, the more intense is their knowledge acquisition in opportunity recognition.

Hills (1995) found that entrepreneurial/managerial experiences enhanced knowledge acquisition. De Koning and Muzyka (1996) pointed out as well that entrepreneurs who had prior experience in entrepreneurship and/or management acquired knowledge more frequently. In addition, Hills et al. (1997) and Hills and Shrader (1998) illustrated that entrepreneurs with prior entrepreneurial/managerial experience search actively new knowledge of opportunities. **H1c:** The higher the management experience of entrepreneurs, the more intense is their knowledge acquisition in opportunity recognition.

Kaish and Gilad (1991) suggested that entrepreneurs who achieved success lost their motivation to search new opportunities. Herron and Sapienza (1992) noticed that intrinsic motivation has a very important role in the knowledge acquisition of opportunities. They proposed that only after entrepreneurs are motivated to change their lives somehow and search for opportunities for their own business does knowledge acquisition start. Sigrist (1999) also stressed that intrinsic motivation "kicks" entrepreneurs to search opportunities. Drucker (1998), who has studied the sources of opportunities, has stated that entrepreneurs need full commitment to entrepreneurship before the gap finding is possible. Manimala (1992, 1996) illustrated how high-innovative entrepreneurs spent more time continuously searching for new opportunities, and what was important they were intrinsically motivated to do that. The study by Hills (1995) also revealed that knowledge acquisition was activated by the intrinsic need to find a business. **H1d:** The higher the intrinsic motivation of entrepreneurs, the more intense is their knowledge acquisition in opportunity recognition.

Gilad (1984) considered opportunity recognition to be creative behavior. He suggested that creativity is needed to acquire information and connect pieces of information to form a new opportunity. On the basis of this, it is argued that creativity enhances knowledge acquisition as it gives cognitive thinking tools to connect pieces of information that superficially look as if they do not have anything to do with each other into knowledge of an opportunity. Hills and Lumpkin (1997) illustrated how entrepreneurs spend quite a lot of time creatively thinking about the information they have received (see

also Hills et al. 1997; Hills and Shrader 1998). Hills, Shrader and Lumpkin (1999) go further and propose that opportunity recognition is inherently creativity of entrepreneurs. They see that in order for knowledge acquisition to happen creativity is needed. De Koning and Muzyka (1996) saw also that entrepreneurs used their creative capabilities to turn the complex information into the knowledge of the situation. **H1e:** The higher the creativity of entrepreneurs, the more intense is their knowledge acquisition in opportunity recognition.

### **Hypotheses 2a–2e: Effects of Intellectual Capital of Entrepreneurs on Competitive Scanning in Opportunity Recognition**

Long and McMullan (1985) found that entrepreneurs use their domain knowledge to scan the competitive arena. De Koning and Muzyka (1996) proposed that the experience of entrepreneurs made them actively scan the competitive environment in order to find gaps that are big enough for profitable business but not big enough to make big companies interested. Hills and Lumpkin (1997) propose that entrepreneurs see competitive scanning to be very important in opportunity recognition, and this to be affected by the level of domain knowledge. Christensen and Peterson (1990) suggested as well that domain knowledge is very important to able to understand markets and competitors in it. The above studies all propose that domain knowledge should increase competitive scanning. **H2a:** The higher the domain knowledge of entrepreneurs, the more intense is their competitive scanning in opportunity recognition.

Active competitive scanning of skilled entrepreneurs was noticed by Woo et al. (1992). Hills (1995) and Hills and Lumpkin (1997) have suggested that formal knowledge might affect competitive scanning positively. De Koning and Muzyka (1996) proposed as well that formal knowledge enhances competitive scanning. It is proposed that formal knowledge offers tools that could be used to analyze

more effectively the competitive arena. **H2b:** The higher the formal knowledge of entrepreneurs, the more intense is their competitive scanning in opportunity recognition.

Thakur (1999) proposed that management experience is needed in order to be able to scan the competitive arena. Hills et al. (1997) and Hills and Shrader (1998) also pointed out that prior experience of entrepreneurship and/or management is needed in competitive scanning. De Koning and Muzyka (1996), then, found that experienced entrepreneurs put a lot of effort into understanding markets. The positive effect of management experience on competitive scanning is also supported by the study by Christensen et al. (1994). **H2c:** The higher the management experience of entrepreneurs, the more intense is their competitive scanning in opportunity recognition.

Gaglio and Taub (1992) showed that entrepreneurs, who relied on their intrinsic motivation, put more effort into trying to understand competition. Manimala (1992) pointed out that intrinsically motivated high-innovative entrepreneurs scanned competition intensively. De Koning and Muzyka (1996) showed how entrepreneurs enjoyed the scanning of the competitive arena. This illustrates clearly how intrinsic motivation enhances competitive scanning. Hills and Lumpkin (1997) showed how entrepreneurs were internally eager to scan competition suggesting that intrinsic motivation would increase competitive scanning. **H2d:** The higher the intrinsic motivation of entrepreneurs, the more intense is their competitive scanning in opportunity recognition.

Hills et al. (1999) noticed that competitive scanning requires skills to creatively question the market situation. This is supported by Hills and Lumpkin (1997), Hills et al. (1997), and Hills and Shrader (1998), according to whom creativity plays an important role in searching for knowledge of a competitive arena and making competitive decisions. De Koning and Muzyka (1996) also pointed out that successful entrepreneurs use their creativity to find market niches. In addition, Sigrist (1999) and Shane and Venkataraman (2000) argue about the skills to link information into new solutions invisible to others, i.e. creativity to give possibilities of flexibly learning from customers, intuitively read market

dynamics, and impulsively react to situations. **H2e:** The higher the creativity of entrepreneurs, the more intense is their competitive scanning in opportunity recognition.

### **Hypotheses 3a–3e: Effects of Intellectual Capital of Entrepreneurs on Proactive Searching in Opportunity Recognition**

According to Cooper (1981), the knowledge of domain gives tools to search for future changes in a business environment. Peterson (1985), as well, underlined how experience is used to proactively position a venture in a business arena. Domain knowledge, thus, creates a kind of cognitive map, which could be used to build a vision of what will happen. It is probable that those who don't know the domain see the future just when it is already the reality. Hills (1995) also indicated this, suggesting that experience in the domain lead entrepreneurs rather to vision of what will happen than to what has happened. Rea et al. (1999) proposed that entrepreneurs construct visions of the future without exact information but merely on the basis of their experience. This is line with the study by Baron (1998), who revealed that entrepreneurs easily fix their eye on the future because their prior experiences advise them to do that. Regrets for past behavior are not leading anywhere. Last, the importance of domain knowledge is clearly shown by Martello (1994). He argues that opportunity recognition is serendipitous future scanning, in which previous experiences in the domain have a central role. **H3a:** The higher the domain knowledge of entrepreneurs, the more intense is their proactive searching in opportunity recognition.

Christensen and Peterson (1990) showed that what is needed besides domain knowledge is also general alertness, i.e. formal knowledge, to be capable to strategic thinking. This contains the idea that formal knowledge is needed to strategically see the future. Hills and Lumpkin (1997) found that entrepreneurs were able to transfer general opportunity recognition skills to different types of situations than

the domain they were familiar with. This also implies that more general skills to use knowledge are used to proactively search for future opportunities. Most importantly, Zietsma (1999) indicated that higher technical education significantly increased the likelihood of deliberate future scanning of opportunities. Herron and Sapienza (1992), as well, stress that formal skills affect positively proactive opportunity searching. **H3b:** The higher the formal knowledge of entrepreneurs, the more intense is their proactive searching in opportunity recognition.

Hills et al. (1997) and Hills and Shrader (1998) indicated that behavior that characterized opportunity recognition was proactive searching for future possibilities. What they also found was that these entrepreneurs had experience in entrepreneurship and management of ventures. This is supported by the study by de Koning and Muzyka (1996), in which they came to the conclusion that experienced entrepreneurs have a skill to vision the future. In addition, Kaish and Gilad (1991) showed how experienced entrepreneurs were able to interpret the information cues. **H3c:** The higher the management experience of entrepreneurs, the more intense is their proactive searching in opportunity recognition.

The study by Baron (1998) was interesting in respect of the motivational background of entrepreneurs searching for opportunities. It showed that entrepreneurs were intrinsically motivated to search for future opportunities. Entrepreneurs were not so much concerned with the past or even the present. Thus, intrinsic motivation for entrepreneurship turn they attention to the future and proactive behavior. Martello (1994) as well suggested that entrepreneurs are highly motivated to work in the field that interests them. At the same time they scan information cues in order to recognize future possibilities. Thus, intrinsic motivation pulls them to proactive searching, at the same time as they are working at other things in the field. In addition, based on the study by Hills (1995) it is possible to see how passionate interest in the domain makes entrepreneurs search for proactive ideas. **H3d:** The higher the intrinsic motivation of entrepreneurs, the more intense is their proactive searching in opportunity recognition.

According to Gilad (1984), creativity is the main cognitive vehicle of human beings in proactive behavior. Hills (1995) and Hills et al. (1999) also proposed that creativity enhances future scanning of opportunities. Christensen et al. (1994) put forward that capability to turn problems into possibilities is linked to the ability to strategically think of the future of the business. De Koning and Muzyka (1996) also suggested that creativity supports proactive behavior. **H3e:** The higher the creativity of entrepreneurs, the more intense is their proactive searching in opportunity recognition.

#### **Hypotheses 4a–4e: Effects of Intellectual Capital of Entrepreneurs on Innovative Behavior in Opportunity Recognition**

Hills (1995) showed that successful entrepreneurs, who were experienced in their field, created ideas actively. Further, Hills et al. (1999) argued that domain knowledge should increase innovative behavior. Manimala (1992, 1996), then, found that more innovative entrepreneur knew customers, dealers, supplier, and others dealing with the products and services in that industry better. Thus, domain knowledge enhanced innovative behavior. **H4a:** The higher the domain knowledge of entrepreneurs, the more intense is their innovative behavior in opportunity recognition.

Christensen and Peterson (1990) came to the conclusion that formal knowledge of a market or a technology might be the source of innovative venture ideas. This suggests that formal knowledge should support innovative behavior. Gaglio and Taub (1992) pointed out, when studying opportunity recognition of entrepreneurs and managers, that managers were more skilled innovators. This suggests that formal knowledge, which is arguably higher among managers, affects innovative behavior positively. Zietsma (1999) also found that both high-tech entrepreneurs (high formal knowledge) and managers (high formal knowledge) were good at innovating ideas. The reason for this might be as Shane and Venkataraman (2000) suggested that some are better at processing information than others. This

skill to process information is probably enhanced by formal education, which provides general thinking skills (see Mayer 1992). **H4b:** The wider the formal knowledge of entrepreneurs, the more intense is their innovative behavior in opportunity recognition.

Cooper (1981) stressed managerial experience to support innovative opportunity recognition. Thakur (1999) proposed that without managerial capabilities it would be difficult to create solutions that are useful and appropriate. Hills (1995), Hills et al. (1997), and Hills and Shrader (1998) studied entrepreneurs with prior entrepreneurial and/or managerial experience and found that they spend quite a lot of time playing with ideas. **H4c:** The wider the management experience of entrepreneurs, the more intense is their innovative behavior in opportunity recognition.

Gaglio and Taub (1992) noticed that entrepreneurs were intrinsically motivated in their innovative behavior. Manimala (1992) came to the conclusion that intrinsic motivation increased innovative behavior. The results reached by Hills (1995) suggested that internal motivation enhances innovative behavior. It is also interesting that internal motivation to work with other people enhances innovative behavior (Steyaert, Bowen and Van Looy 1996). **H4d:** The higher the intrinsic motivation of entrepreneurs, the more intense is their innovative behavior in opportunity recognition.

Gaglio and Taub (1992) proposed that entrepreneurs use their creativity to innovate ideas. Hills (1995) studied opportunity recognition of successful entrepreneurs and found out that they frequently try to innovate ideas. On the other hand, the entrepreneurs said that they use creative thinking as a tool for this. In the studies of Hills and Lumpkin (1997), Hills et al. (1997), and Hills and Shrader (1998) entrepreneurs also told the authors that they frequently use creativity in order to play with new ideas, i.e. to innovate. De Koning and Muzyka (1996) pointed out that entrepreneurs use their personal creativity to innovate new opportunities. **H4e:** The higher the creativity of entrepreneurs, the more intense is their innovative behavior in opportunity recognition.

## **Hypotheses 5a–5e: Effects of Intellectual Capital of Entrepreneurs on Collective Action in Opportunity Recognition**

De Koning and Muzyka (1996) pointed out that experienced entrepreneurs discussed intensively with their social context. The authors found that opportunity recognition was affected especially by expertise in the field and skills to communicate socially to find opinions, advise, information, and partners. In addition, domain knowledge created such self-confidence among the entrepreneurs that they were open to their own weaknesses and relied on other people. The above results show quite clearly how domain knowledge increases collective action because it gives such self-esteem that you do not have to know everything and that you are "allowed" to discuss with other people without the fear that they steal your idea, or think "what a silly thought". This common trust in others might be created through social conversations (Steyaert et al. 1996), in which parties together create domain knowledge, which then enhances further collective action. Hills and Lumpkin (1997) found that collective, social action with other people was one of the most important ways to look for opportunities in markets (see also Christensen et al. 1994). **H5a:** The higher the domain knowledge of entrepreneurs, the more intense is their collective action in opportunity recognition.

Burt (1992) has indicated that formal knowledge increases collective action. According to him, formal knowledge makes it possible to have higher positions in companies and hierarchies and., thus, better positions in a network structure. This, then, increases the collective action with information sources and not just with anybody. Manimala (1992) pointed out that highly innovative entrepreneurs developed their formal technical capabilities before they started to collaborate. This might mean that formal knowledge is needed in order to be ready for collective action. Hills et al. (1997) came to the conclusions that networking entrepreneurs were able to scan opportunities from a wide base. This suggests that networking entrepreneurs might have more general skills to process information than only in

the familiar context. This, again, suggests that formal knowledge might create more active collective action. **H5b:** The wider the formal knowledge of entrepreneurs, the more intense is their collective action in opportunity recognition.

Kaish and Gilad (1991) pointed out that although experienced entrepreneurs like to think themselves about their ventures they still gather opinions and actively discuss business issues with other people. Hills (1995) introduced that successful entrepreneurs, who had management experience, were active socially. De Koning and Muzyka (1996) also indicated that entrepreneurs with prior entrepreneurial/managerial experience discussed a lot with other people and even asked their opinions of questions in which they were not experts. Hills and Lumpkin (1997) proposed that entrepreneurial experience enhances network behavior. Last, Singh, Hills, Hybels and Lumpkin (1999) also showed how management experience produces intense collective action. **H5c:** The wider the management experience of entrepreneurs, the more intense is their collective action in opportunity recognition.

According to Manimala (1992) highly innovative entrepreneurs were intrinsically motivated and spend time discussing with their social relationships. De Koning and Muzyka (1996) also noticed that internally passionate and self-confident entrepreneurs were willing to discuss their venture ideas with other people. Last, Sigrist (1999) found that an own personal line of entrepreneurs supports interaction with external resource holders. **H5d:** The higher the intrinsic motivation of entrepreneurs, the more intense is their collective action in opportunity recognition.

Gilad (1984) suggested that entrepreneurs need creative capabilities in order to be able to see links between many types of information and that this information is achieved by collective action. Gaglio and Taub (1992) followed Gilad's (1984) ideas and indicated that those individuals who were more creative were also ready and willing to go in for social interaction. Hills (1995) also expressed the notion that entrepreneurs spent time thinking creatively about business ideas and taking active part in social dialogue (see also de Koning and Muzyka (1996). Rea et al. (1999) proposed that creativity and

social networking of entrepreneurs go hand in hand in opportunity recognition. **H5e:** The higher the creativity of entrepreneurs, the more intense is their collective action in opportunity recognition.

#### **4. Methodology**

The sample was drawn from Trade Register of Finland. The sample was defined by three criteria: First criterion was that firms must be established in 1998. Second criterion was that the regions of Jyväskylä, Oulu, and Vaasa in Finland were chosen. Third criterion was that metal- and information- and communication technology (ICT) firms were chosen. Metal- and ICT-industry sectors were defined and firms chosen based on the industry categories presented by Statistic Finland.

A questionnaire was designed based on the literature review (see Appendix 1). Factor analysis and the Cronbach alpha reliability coefficient were used to confirm the unidimensionality and inter-item reliability of constructs. The items were measured on a seven-point Likert-scale, where the choices ranged from 1 = strongly disagree to 7 = strongly agree. Measurement items, sources, and factor loadings are presented in Appendices 2 and 3. As a pilot test, three entrepreneurs from firms representing the population filled out the questionnaire. The main effect was that wording was changed to simpler and more exact. The three entrepreneurs in the pilot test were excluded from the sample. A total of 101 firms out of 213 firms returned the questionnaire.

In the data analysis was used structural equation modeling with AMOS-software. It is suggested that sample size in structural equation modeling should be counted so that there are at least five observations per parameter. In the present study there are in the hypothesized model 19 parameters and 101 observations, so the sample size is just enough (Schumacker and Lomax 1996).

The dependent and independent variables were operationalized in the following way: The dependent variables are knowledge acquisition, competitive scanning, proactive searching, innovative be-

havior, and collective action. Four items measured knowledge acquisition. The items were adopted from a study by Miller (1987). The items asked whether an entrepreneur gathered a lot of information on sales, gathered a lot of information on markets, did organized work to find an opportunity, and made forecasts about technological developments.

Competitive scanning was measured in the questionnaire by using three items (see Miller 1987). First, it was asked if the entrepreneurs had a strong proclivity for high-return projects, even though they involved high risk. Second, it was inquired in the questionnaire whether the entrepreneurs went in for bold and wide-ranging actions in opportunity searching. Third, it was asked whether the entrepreneurs tried to find original ideas.

Proactive searching was measured using three items (Miller 1987). The first of the measurement items asked whether the entrepreneurs did long-term planning. The second item asked whether the entrepreneurs tried to find an opportunity with high newness-value. The third question asked whether the entrepreneurs purposefully spent time on creativity.

Innovative behavior was measured through two items (Miller 1987). First, it was asked whether the searching is about trial and error with ideas and, second, whether entrepreneurs played and tried many different things. Two items also measured collective action. First, it was asked whether the entrepreneurs preferred to work alone rather than together with others. Second, it was asked whether the entrepreneurs negotiated and discussed a lot with other people.

The independent variables are domain knowledge, formal knowledge, management experience, intrinsic motivation, and creativity. Domain knowledge was measured by using three items. The first of them asks how similar entrepreneurs' recent customers are to the customers of the former employers of the entrepreneurs. The second item asks how similar the products of the entrepreneurs are to the former employers' products. Last similarity of suppliers is asked about. These questions are applied from the study by Gimeno et al. (1997).

Two items measured formal knowledge. These are, first, education of entrepreneurs and, second, technical skills of entrepreneurs. Phan and Lee (1995) and Gimeno et al. (1997) indicated these items to well reflect the knowledge of the theories, rules, knowledge etc. of the domain, i.e., formal knowledge of entrepreneurs.

Management experience was measured by using two items inquiring experience of managerial actions and entrepreneurial actions. The questions were adopted from Gimeno et al. (1997).

Five items measured the intrinsic motivation of entrepreneurs. The first item measures how strongly entrepreneurs wanted to show that they are able do it. The second item asked if entrepreneurs felt the situation as a challenge. The third question inquired how important it was that they were able to do work they enjoy. Fourth by it was asked how much entrepreneurs wanted to be respected by others. The fifth item measured the need to develop as a human being. These questions were adopted from the studies by Gimeno et al. (1997) and Kuratko, Hornsby and Naffziger (1997).

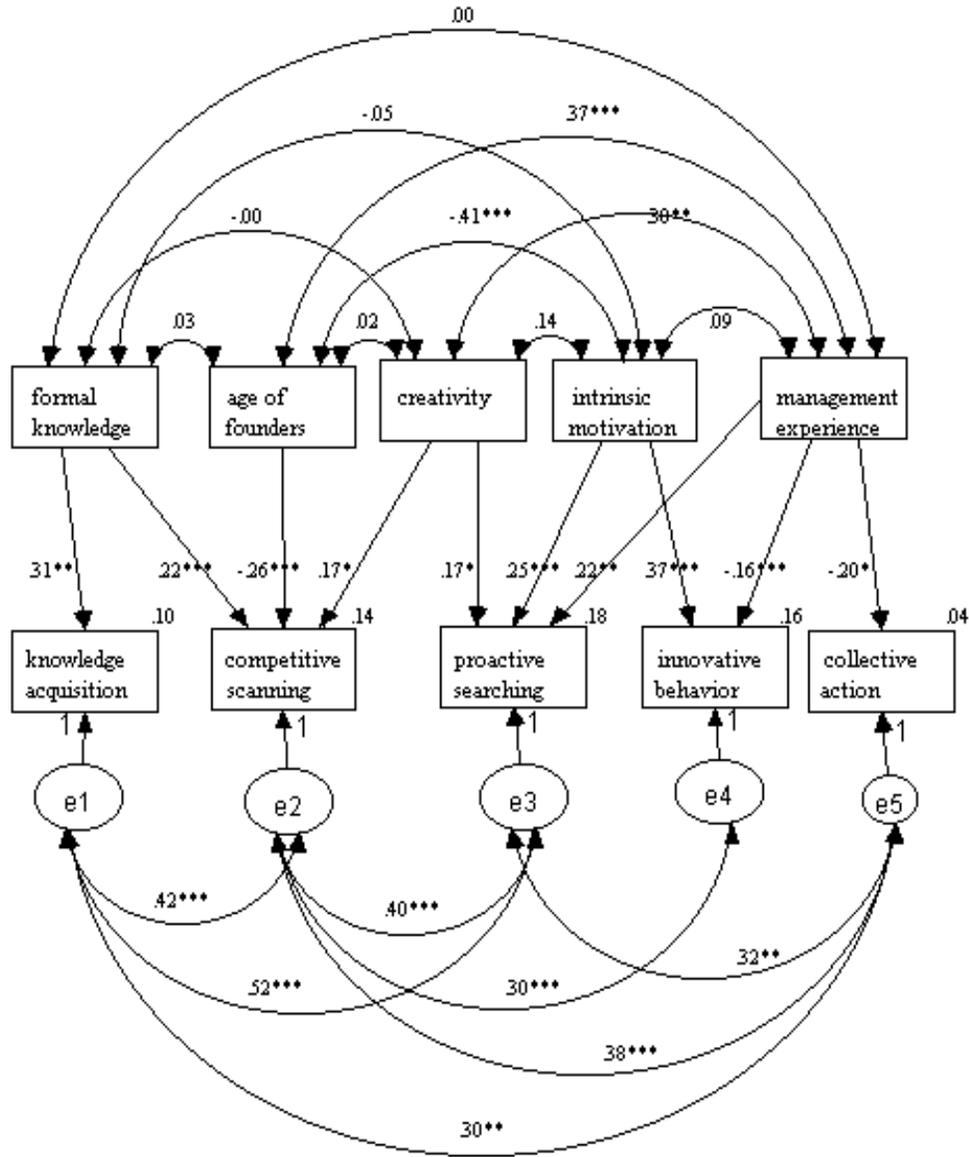

Five items measured creativity of entrepreneurs. First is asked how good an entrepreneur is when it comes to questioning normal ways of doings things. Second is asked how sensitive an entrepreneur is to seeing the kind of problems that others can't see. The third item asks how often new solutions come into an entrepreneur's mind though not necessarily wanted. The fourth item concerns originality of ideas. The last item asks if an entrepreneur has plenty of ideas. The questions are adopted from the studies by Kivikko (1977) and Vesalainen and Pihkala (1998).

The control variables of the study were age of founders, initial amount of capital, number of employees in the beginning, and radius of business in the beginning.

## 5. Results

The model was first run with the AMOS structural equation modeling program. The model was identified (see Figure 1). Second, error variances ( $e_1$ – $e_4$ ) were examined for negative or non-significant error variances. None of these types of results were found. Third, it was checked that none of the model coefficients were close or over 1 and standard error coefficients unusually large. Problems in respect of these issues are not to be expected. Third, multicollinearity of the exogenous variables was studied, and it was found that none of the correlations were above 0.80. Thus, multicollinearity should not cause trouble (Schumacker and Lomax 1996).

Knowledge acquisition in opportunity recognition was significantly affected only by formal knowledge of intellectual capital. This shows that formal education and -skills provide general abilities that could be used in turning pieces of information into useable knowledge. Knowing well the theories, rules, techniques, etc. of the domain offers tools to analyze the situation and create knowledge of the situation. Even though knowing the theories, rules, techniques, etc. is crucial in order to be able to analyze the situation, this type of knowledge is quite abstract to be used straightforwardly in real business-creating situations. Thus, entrepreneurs get involved in knowledge acquisition in opportunity recognition in order to combine both their abstract and empirical knowledge. Figure 1 illustrates the results with the standardized maximum likelihood parameter estimates for the paths.

Causal coefficients are standardized beta weights.  
 \*\*\*  $p \leq .001$ . \*\*  $p \leq .01$ . \*  $p \leq .05$ .

**Figure 1.** The effects of intellectual capital on opportunity recognition.

Formal knowledge affected significantly and positively competitive scanning. Thus, those who have learned the formal tools of thinking and had a thorough knowledge of the domain were able and willing to analyze competition and competitors and find more aggressively their own place in the competitive arena. Creativity also affected significantly and positively competitive scanning. This indicates

that by using creativity it is possible to understand the competitive arena in exceptional ways and see clues for opportunities that others are not able to see (Kirzner 1997). Creativity, thus, makes it possible to interpret the information from the competitive arena so that entrepreneurs perceive anomalies in the arena. Of the control variables, age of entrepreneurs influenced negatively competitive scanning. Thus, when the age of entrepreneurs rises, they do not analyze competition so actively. The reason for this might be that experience develops confidence in one's capabilities, and competitive scanning is set aside. Also it is possible that the age of entrepreneurs changes how entrepreneurs in general think about business and life as a whole. They are more willing to make room for others and less eager to compete.

It is interesting that management experience was used in proactive searching and not for knowledge acquisition or competitive scanning. Thus, management experience affected significantly and positively proactive searching. This result suggests that experience is used rather for intuitive future forecasting than for rational analyzing of the present situation. It is, thus, possible to suggest that management experience offers understanding of what has happened in the business before, what is happening now, and what will happen in the future. In this way by using management experience entrepreneurs are able to predict future trends and search proactively for opportunities. Intrinsic motivation also had a positive effect on proactive searching. This result could be interpreted so that searching for future opportunities requires more internal motivation from individuals than analyzing the present situation. Proactive searching of newness is about linking a complex set of weak cues, and to be motivated to do this demanding work, intrinsic motivation of entrepreneurs must be high. This result that intrinsic motivation do not support more rational analyzing, indicates that intrinsic motivation is connected more with intuitive searching for new possibilities than for rational information organizing. In addition, creativity enhanced significantly proactive searching. It is possible to propose that in proactive searching intrinsic motivation gives the enthusiasm, management experience the knowledge, and creativity mental information-processing tools.

Management experience affected significantly and negatively innovative behavior. This illustrates how experience decreases the flexibility of thinking and directs it to be close to prior experiences, thus affecting negatively questioning the present and innovating something new. This phenomenon is known as path-dependency, in which an individual stays in the path that is familiar to him/her in respect of his/her prior experiences (see e.g. Tversky and Kahneman 1974). Intrinsic motivation enhanced strongly innovative behavior. Research on creativity (e.g. Amabile 1997) has revealed that one of the most important factors supporting free play of ideas is the internal will of an individual to play for the sake of playing without any concrete and explicit goals.

Management experience affected as well significantly collective action. However, opposite to expected the effect was negative. This is an unexpected result because it would be reasonable to expect that the more management experience you have more willing and enterprising you are to work with others. But the above result indicates that instead through management experience entrepreneurs learn to count and make the decisions themselves and to keep others out of their opportunity recognition. This result, like results above, illustrates how prior experiences cause biases in thinking and overwhelming confidence in present knowledge.

### **The goodness-of-fit of the model and nested model tests**

The goodness-of-fit statistics in Table 1 below indicate a good fit between the hypothesized model and the data. The chi-square value of 20.55 with 18 degrees of freedom is not significant ( $p=.30$ ), indicating that the estimated and observed data matrices do not differ significantly. Further, the GFI value of 0.96 and the AGFI value of 0.88 indicate reasonable good fit between the model and the data. The AGFI value does not reach the recommended value of 0.90 (Schumacker and Lomax 1996) but is very close to it. Good fit is also supported by the NFI value of 0.92, which is clearly above the recommended 0.80.

The model fit was further assessed using nested model tests. The rival models are compared with each other in respect of the fit of the model to the data. Three rival nested models were compared: (1) the hypothesized model, (2) a null model, in which no relationships are posited, and (3) a saturated model, in which all the possible relationships are posited. As Table 1 shows, the null model does not fit the data because its chi square statistics indicate significant difference between the observed and estimated data matrices. Also GFI and AGFI values are clearly under 0.90 and NFI value under 0.80. The saturated model has a good fit between the observed and estimated data matrices. Also the other fit measures are acceptable. Nevertheless, the hypothesized model fits a little better. In addition, because the more parsimonious model (the hypothesized) fits better than the more complicated one (saturated), the more parsimonious model is chosen. The above results of the nested models increase the validity of the hypothesized model because the fits of both the simpler and the more complicated model were weaker than the fit of the hypothesized model.

**Table 1.** Structural equation model statistics for the intellectual model.

| Model           | Chi <sup>2</sup> | p   | df | GFI | AGFI | NFI |
|-----------------|------------------|-----|----|-----|------|-----|
| 1. Hypothesized | 20.55            | .30 | 18 | .96 | .88  | .92 |
| 2. Null         | 90.26            | .00 | 28 | .85 | .71  | .59 |
| 3. Saturated    | 4.45             | .22 | 3  | .98 | .84  | .90 |

## 6. Discussion

The prior studies of opportunity recognition have regarded formal knowledge to be less important than domain knowledge (see e.g. Hills 1995). However, formal knowledge has been widely seen to have an important role in knowledge acquisition as it gives more general analyzing tools to interpret informa-

tion (Christensen and Peterson 1990; Woo et al. 1992; Zietsma 1999). The results of this study were in line with the results of these previous studies. The results of the study pointed out, first, that knowledge acquisition requires formal knowledge of particular domain. This was also indicated by Woo et al. (1992) and Zietsma (1999). With formal knowledge entrepreneurs are able to analyze and synthesize information to create usable knowledge. However, the study disagrees with the previous studies as regards the idea that also domain knowledge, management experience, intrinsic motivation, and creativity should enhance knowledge acquisition. The results of this study suggest instead that knowledge acquisition is very rational, purposeful behavior that requires mostly formal abilities to analyze information and perhaps even strength to put aside the rest of the intellectual capital an entrepreneur possesses.

Prior research has strongly argued that domain knowledge of a particular profession should enhance opportunity recognition (e.g. Kaish and Gilad 1991; Woo et al. 1992; de Koning and Muzyka 1996; Hills and Lumpkin 1997). Shane and Venkataraman (2000) argue even that opportunity recognition is possible only when an entrepreneur has knowledge structures, i.e. domain knowledge, of that particular domain. Otherwise, entrepreneurs would not see what they should search for and what they should do with the information. Woo et al. (1992) indicated that less experienced entrepreneurs did not search because their lack of knowledge produced the bias that new knowledge is not important. This study revealed that the relationship is positive but at least here not significant. This might point out that experienced entrepreneurs in the domain rely on their existing knowledge and only fill the gaps they have. This suggests, as research on cognitive knowledge structures has revealed (Tversky and Kahneman 1974), that prior knowledge interferes and cause biases in thinking and behavior. Baron (1997, 1998) already indicated that this is possible in opportunity recognition. Thus, domain knowledge enhances opportunity recognition, but after some point, when domain knowledge is quite high, it starts to interfere with opportunity recognition because of the bias to think that it is known enough already (see Baron 1998). Hereafter, this study points out that domain knowledge might be important, as previous

studies have strongly argued, but it can also be dangerous when interfering with opportunity recognition behavior.

Second, prior studies have strongly argued competitive scanning to be based on domain knowledge, as it would offer the tacit knowledge of the area (Cooper 1981; Long and McMullan 1985; de Koning and Muzyka 1996; Hills and Lumpkin 1997; Kirzner 1997). However, this study revealed that formal knowledge is more important in competitive scanning than domain knowledge. The reason for this might be that knowing the business and actors there (domain knowledge) do not show where the anomalies are in the competitive arena. What is needed is also and especially formal analyzing- and technical skills to see where and what kind of gaps are going to open up.

The results also indicated that creativity is significant in competitive scanning. This was in line with previous results (e.g. Hills et al. 1999). It is interesting that creativity is significant but domain knowledge is not. This implies that tacit knowledge, or in other words alertness to connections between pieces of information that is needed, is involved in capabilities of entrepreneurs to process information in novel ways and not in knowing the business per se. This is also suggested by the fact that management experience was not significant in competitive scanning. This shows further that experience does not tell what kind the competitive arena is but that what is needed is ability to formally analyze it and willingness to creatively play with information to create in minds of entrepreneurs awareness of anomalies that are going to open. Interesting is also that intrinsic motivation is not so important, although it is proposed that competitive scanning is demanding emotionally (e.g. Herron and Sapienza 1992). This indicates that competitive scanning is not fun but hard work that must be done. Because it is an unpleasant job, it is thus possible that experienced entrepreneurs avoid it. Many times entrepreneurs even try to escape boring work and perhaps thus also avoid competitive scanning (see Kuratko et al. 1997). As a whole, in competitive scanning formal knowledge proposes the tools that are needed to understand the competition and creativity vehicles to see anomalies in this competition.

Previous studies have argued that proactive searching requires both domain- and formal knowledge (e.g. Woo et al. 1992; Christensen et al. 1994; Hills 1995). However, the results of the present study revealed that proactive searching is not about rational analyzing of information but merely intuitive visioning of the future. The results indicated that proactive searching is enhanced by prior management experiences, intrinsic motivation, and creativity of entrepreneurs. Proactive searching, which is more about abstract projecting of the future than rational and “hard” analyzing of the present situation, calls for knowledge of how an industry is developing in a larger frame (Hills et al. 1997; Hills and Shrader 1998). This knowledge is dependent on managerial/entrepreneurial experiences. In other words, if you have worked as a manager and/or an entrepreneur, it is probable that you have a vision of larger trends in that business, and thus you have also capabilities to forecast in some extent the future. However, proactive searching requires also strong intrinsic motivation to be able to explore the future. This is so maybe because proactive searching is largely based on intuitions, which are possible only if an individual is really internally motivated. Intuitions are not possible to create by force or necessity (see Manimala 1992; Martello 1994; Hills 1995; Baron 1998). Creativity is also necessary to be able to link weak information cues so that an entrepreneur recognizes future developments (Gilad 1984; Hills and Shrader 1998). Present study showed that although rational analyzing of the competitive arena and knowledge acquisition are very important in order to know what the industry stands for creative and intuitive visioning of future possibilities is the most crucial part of opportunity recognition. Thus, it should be underlined that, when capabilities to recognize opportunities are developed, serious time and effort should be given to developing creative and intuitive capabilities as well.

The results of this study indicated that innovative behavior is not enhanced by level of knowledge. Instead, innovative behavior is probably very natural to all human beings and thus it needs only intrinsic motivation to be turned on (Amabile 1997). Innovative behavior needs strong intrinsic motivation, since it is internal, mental playing with ideas. It is impossible if an entrepreneur does not enjoy it.

Innovativeness is hard to rationalize and thus it needs a pull from inside. Thus, this study agrees with Gaglio and Taub (1992) and Manimala (1992), who have suggested that innovative behavior in opportunity recognition requires a strong motivational ground. Management experience, again, decreases innovative behavior. This points very clearly how existing knowledge might hinder free play with ideas (Baron 1998). The fact that creativity does not enhance innovative behavior further shows that although innovative behavior is not about rational processing of information neither it is totally creative but has certain goals to obtain.

All the other variables besides management experience did not have any significant effect on collective action. Many studies have proposed that collective action is also a result of individual capabilities (de Koning and Muzyka 1996; Steyaert et al. 1996; Hills and Lumpkin 1997; Hills et al. 1997; Singh et al. 1999). However, this study proposes that collective action is merely learned in a social community and is thus a social phenomenon. Thus, in spite of intellectual capital, entrepreneurs can behave socially collectively dependent on how used they are to social behavior. Still, management experience hindered collective action. On the basis of this, it seems that managerially and/or entrepreneurially experienced persons want to control themselves the actions and decisions in opportunity recognition and keep others out. Perhaps experienced managers/entrepreneurs feel that somehow new opinions threaten their own opinions. On the other hand, management experience might create cognitive biases that cause managerially experienced entrepreneurs to trust themselves too much (Baron 1997, 1998). This shows again how dangerous experience can be if it is used in an inflexible way.

## Appendices

### Appendix 1. The survey instrument of the study.

| Name and company   |  |
|--|--|
| <b>I. INTELLECTUAL CAPITAL</b>   |  |
| First group of questions deals with your personal qualities in time you were establishing your company under the study. The questions/statements are presented on the left side and possible answers on the right side of the page. Please read the questions/statements carefully and CIRCLE the number that <b>best</b> suits for you.   |  |
| .....  |  |
| 1. Which one of the followings is closest to your formal degree of education at the time of you established your company?  | 1 = no formal education<br>2 = elementary school<br>3 = vocational school/high school<br>4 = engineering school, commercial institute etc.<br>5 = polytechnic degree<br>6 = university degree<br>7 = licentiate/doctoral degree  |
| .....  |  |
| 2. How much did you have work experience from your company's field of business at the time of you established your company?  | 1 = less than a year<br>2 = less than 2 years<br>3 = less than 4 years<br>4 = less than 6 years<br>5 = less than 8 years<br>6 = less than 10 years<br>7 = 10 years or more   |
| .....  |  |
| 3. What were your main objectives when you started your company? Mark a cross beside those which were important to you (in the box) and number 1 (on the line) beside that one which was the most important one.   | <input type="checkbox"/> ___ = I hadn't any specific objectives or goals<br><input type="checkbox"/> ___ = my objective was to have a company and my recent job at the same time<br><input type="checkbox"/> ___ = my objective was to create a job for me<br><input type="checkbox"/> ___ = my objective was to create a family company, which I could then hand over to my children in the future<br><input type="checkbox"/> ___ = my goal was to establish a company, develop it further, sell it for a good price, and enjoy the fruits of my work<br><input type="checkbox"/> ___ = my objective was to establish first one company, and then when its life-cycle would end, establish a new company<br><input type="checkbox"/> ___ = my objective was to establish little by little several companies and run them at the same time. |
| .....  |  |
| 4. How close the products of your company were to products of your prior employees*?<br>* Think the situation at the moment of your company's establishment as the situation of your company might have been changed.  | 1 = completely different<br>2 = quite different<br>3 = a little different<br>4 = neutral<br>5 = a little similar<br>6 = quite similar<br>7 = very much the same  |
| .....  |  |
| 5. What were your technical capabilities* in the line of business in which your company was at the moment of establishment?<br>*By technical capabilities is meant here for example medical doctor's knowledge when heart transplant is needed, mechanic's knowledge how to change piston rings and why those are needed in an engine, or construction supervisor's knowledge how humidity affects building structures and how this is eliminated. | 1 = no technical capabilities<br>2 = beginner<br>3 = trainee<br>4 = skilled worker<br>5 = skillful<br>6 = expert<br>7 = "world beater"   |

6. How much did you have management experience\* at the moment of your company's establishment?  
 \*By management experience is meant responsibility of decisions, responsibility of planning, implementing, and supervising of issues in an organization, and responsibility of instructing, educating, and developing his/her subordinates.
- |   |                      |
|---|----------------------|
| 1 | = less than a year   |
| 2 | = less than 2 years  |
| 3 | = less than 4 years  |
| 4 | = less than 6 years  |
| 5 | = less than 8 years  |
| 6 | = less than 10 years |
| 7 | = 10 years or more   |

7. How close the customers of your company were to customers of your prior employees\*?  
 \* Think the situation at the moment of your company's establishment as the situation of your company might have been changed.
- |   |                        |
|---|------------------------|
| 1 | = completely different |
| 2 | = quite different      |
| 3 | = a little different   |
| 4 | = neutral              |
| 5 | = a little similar     |
| 6 | = quite similar        |
| 7 | = very much the same   |

8. How much did you have entrepreneurship experience\* at the moment of your company's establishment?  
 \*By entrepreneurship experience is meant prior ownership or significant partnership in a firm in which you and your partners hold the power of decisions.
- |   |                      |
|---|----------------------|
| 1 | = less than a year   |
| 2 | = less than 2 years  |
| 3 | = less than 4 years  |
| 4 | = less than 6 years  |
| 5 | = less than 8 years  |
| 6 | = less than 10 years |
| 7 | = 10 years or more   |

9. How close the suppliers of your company were to suppliers of your prior employees\*?  
 \* Think the situation at the moment of your company's establishment as the situation of your company might have been changed.
- |   |                        |
|---|------------------------|
| 1 | = completely different |
| 2 | = quite different      |
| 3 | = a little different   |
| 4 | = neutral              |
| 5 | = a little similar     |
| 6 | = quite similar        |
| 7 | = very much the same   |

10. What were the important reasons for you to establish a company of your own? Please read the questions/statements carefully and CIRCLE the number that **best** suits for you. Choose only one number per statement. The scale for statements is the following: 1 = not important, 2 = little important, 3 = somewhat important, 4 = moderately important, 5 = quite important, 6 = important, and 7 = very important

|   | <i>not important</i> |   |   |   |   |   | <i>very important</i> |
|---|----------------------|---|---|---|---|---|-----------------------|
| a. I wanted to achieve high personal wealth.                  | 1                    | 2 | 3 | 4 | 5 | 6 | 7                     |
| b. I wanted to have appreciation.                             | 1                    | 2 | 3 | 4 | 5 | 6 | 7                     |
| c. I wanted to show that I can do it.                         | 1                    | 2 | 3 | 4 | 5 | 6 | 7                     |
| d. I wanted to develop as an individual.                      | 1                    | 2 | 3 | 4 | 5 | 6 | 7                     |
| e. I wanted to get higher incomes.                            | 1                    | 2 | 3 | 4 | 5 | 6 | 7                     |
| f. I wanted to enjoy the excitement of being an entrepreneur. | 1                    | 2 | 3 | 4 | 5 | 6 | 7                     |
| g. I wanted to do that kind of work I like.                   | 1                    | 2 | 3 | 4 | 5 | 6 | 7                     |
| h. I wanted to have more money.                               | 1                    | 2 | 3 | 4 | 5 | 6 | 7                     |
| i. I wanted to do work that offers personal challenges.       | 1                    | 2 | 3 | 4 | 5 | 6 | 7                     |
| j. I wanted to create a successful company.                   | 1                    | 2 | 3 | 4 | 5 | 6 | 7                     |

11. How you see your own creativity? Please read the questions/statements carefully and CIRCLE the number that **best** suits for you. Choose only one number per statement. The scale for statements is the following: 1 = I don't agree at all, 2 = I agree a bit, 3 = I agree somewhat, 4 = neutral, 5 = I agree quite a bit, 6 = I agree, and 7 = I strongly agree

- |   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|
| a. I have plenty of ideas.  | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| b. I search for new solutions even then when those are not needed.                      | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| c. I'm alert to see problems which are possible to solve by new solutions.              | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| d. My ideas are often very original.  | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| e. I'm good at questioning the used ways to do things.                                  | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| f. It is easy for me to find proposals for improvement.                                 | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| h. When a wall comes in my way I can find a detour from completely different direction. | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| i. I find special and surprising solutions to problems.                                 | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| j. When I see a new solution, new, additional solutions becomes to come in my mind      | 1 | 2 | 3 | 4 | 5 | 6 | 7 |

## 2. OPPORTUNITY RECOGNITION

Instruction: The early phase of a business before the actual business actions is possible to divide into three phases: (1) business opportunity recognition, (2) planning of business actions, and (3) formal establishment of a business. In the business opportunity recognition phase it is tried to recognize and create that kind of idea for a business that grabbing on that it would be possible to add new value to customers and earn profit to owners. In the planning phase, then, it is planned how this idea for business is possible realize. In the formal establishment the business is then actualized and formally registered by the laws of the country. These phases take place before the business earns any revenues. This study is interested in business opportunity recognition. By an opportunity it is meant here that kind of need in markets that, if this need is served by products and services of the business, it would create that kind of new value for customers that they are willing to buy products and services and by that way earn profit to the business. The above phases are, of course, overlapping in reality but I kindly ask you to think back what and how you did things when you tried to recognize an opportunity for your business. Questions are presented as statements (25).

Please read the questions/statements carefully and CIRCLE the number that **best** suits for you. Choose only one number per statement. The scale for statements is the following: 1 = I don't agree at all, 2 = I agree a bit, 3 = I agree somewhat, 4 = neutral, 5 = I agree quite a bit, 6 = I agree, and 7 = I strongly agree

- |   | <i>I don't agree at all</i> |   |   |   | <i>I strongly agree</i> |   |   |
|---|-----------------------------|---|---|---|-------------------------|---|---|
| 1. I gathered a lot of information on sales, tastes, technology etc. in order to recognize an opportunity.                  | 1                           | 2 | 3 | 4 | 5                       | 6 | 7 |
| 2. I did organized work in order to find an opportunity.  | 1                           | 2 | 3 | 4 | 5                       | 6 | 7 |
| 3. I gathered a lot of information on markets to recognize an opportunity.  | 1                           | 2 | 3 | 4 | 5                       | 6 | 7 |
| 4. I outlined things in a few years perspective when I tried to recognize an opportunity.                                   | 1                           | 2 | 3 | 4 | 5                       | 6 | 7 |
| 5. I used often experts to help me in opportunity recognition.  | 1                           | 2 | 3 | 4 | 5                       | 6 | 7 |
| 6. I tried very actively to sketch that kind of an opportunity that would be  | 1                           | 2 | 3 | 4 | 5                       | 6 | 7 |
| 7. I gathered a lot of information on competitors in order to recognize an opportunity.                                     | 1                           | 2 | 3 | 4 | 5                       | 6 | 7 |
| 8. I didn't plan that carefully my opportunity recognition but it merely just happened and developed in time by itself.     | 1                           | 2 | 3 | 4 | 5                       | 6 | 7 |
| 9. In order to recognize an opportunity I made a lot of forecasts about sales, profit, and nature of markets.               | 1                           | 2 | 3 | 4 | 5                       | 6 | 7 |
| 10. I gathered a lot of information on needs, plans, and opinions of customers in order to recognize an opportunity.        | 1                           | 2 | 3 | 4 | 5                       | 6 | 7 |
| 11. I played with and tried a lot of different and new types of ideas to the industry in order to recognize an opportunity. | 1                           | 2 | 3 | 4 | 5                       | 6 | 7 |
| 12. I had a strong proclivity for high-return projects, despite high risk, rather than for low-profit, low-risk projects.   | 1                           | 2 | 3 | 4 | 5                       | 6 | 7 |
| 13. I purposefully spent time on creativity when I tried to recognize an opportunity.                                       | 1                           | 2 | 3 | 4 | 5                       | 6 | 7 |

|   | <i>I don't agree at all</i> |   |   |   | <i>I strongly agree</i> |   |   |
|---|-----------------------------|---|---|---|-------------------------|---|---|
| 14. I planned far ahead (for example 3 years) already from the phase of opportunity recognition.  | 1                           | 2 | 3 | 4 | 5                       | 6 | 7 |
| 15. I made forecasts about technological developments that would be important to my products and services of my company in order to recognize an opportunity. | 1                           | 2 | 3 | 4 | 5                       | 6 | 7 |
| 16. I preferred to work alone rather than together with others in order to recognize an opportunity (reverse).  | 1                           | 2 | 3 | 4 | 5                       | 6 | 7 |
| 17. I made forecasts about future investment needs in order to recognize an opportunity.  | 1                           | 2 | 3 | 4 | 5                       | 6 | 7 |
| 18. I tried actively to recognize an opportunity that would be growth oriented and innovative rather than thoroughly tried and secure idea.                   | 1                           | 2 | 3 | 4 | 5                       | 6 | 7 |
| 19. I did often organized work to find and evaluate markets, new products, new technologies, etc. in order to recognize an opportunity.                       | 1                           | 2 | 3 | 4 | 5                       | 6 | 7 |
| 20. I tried very actively to recognize an opportunity that would beat competitors rather than let all flowers bloom.  | 1                           | 2 | 3 | 4 | 5                       | 6 | 7 |
| 21. I used often information technology to assist me in my opportunity recognition.   | 1                           | 2 | 3 | 4 | 5                       | 6 | 7 |
| 22. I went actively in for bold, wide-ranging actions in opportunity searching rather than accepted too cautious and thoroughly studied ways of doing things. | 1                           | 2 | 3 | 4 | 5                       | 6 | 7 |
| 23. I liked a lot to negotiate and discuss with other people in order to recognize an opportunity.  | 1                           | 2 | 3 | 4 | 5                       | 6 | 7 |

**Abstract**

In 2003, the Small and Medium Enterprise Center (SMEC) at the Lahore University of Management Sciences undertook a survey of 650 SMEs in the manufacturing sector of Pakistan. This paper presents key findings from the survey. Our results show that firms in the SME sector of the country in general revolve around the owner/entrepreneur. Analysis was done to identify what characteristics of the owner/operating head affect the SME performance. Sales increase/ decrease, sales per employee and investment plans were the performance indicators selected for the analysis. The results showed owners' education, media related habits, use of information technology, number of investors and

generations in business have a significant relationship with the health of the firm. Another key finding of the study was that the SME sector lacks formal systems for employee appraisal & training and quality control. Less than half of the SMEs had bank accounts. Only a handful of firms were into exports. Thus another interesting follow-up question studied was what company/business characteristics have a significant relationship with performance? Our results show positive relationship between firms' performance and whether or not they have formal HR, QC and financial systems in place. Additionally, we also found a positive relationship between firms' performance and percentage of goods exported, number of products produced, number of customers, amount of sub-contracting and whether or not they had better machinery.

## **1. INTRODUCTION**

Like the rest of the world, in Pakistan the small and medium sized enterprises (SMEs) have come under “public policy limelight” (Schlogl 2004) in recent years. Several authors (Bernice et al 1997; Neck 1987) have identified SMEs as source of significant employment potential, revenue generation and technological advancement. The Government of Pakistan established a Small and Medium Enterprise Authority (SMEDA) in 1998 with the aim of developing its burgeoning SME sector. After major setbacks in the larger industrial sector in the mid nineties, most commercial banks in the country have setup specialized departments to cater for the SME sector's financing needs. This followed the establishment of a national SME Bank to finance this sector, considered

crucial to the national economy. Additionally, almost all major international donor agencies (e.g., ADB, World Bank, ILO, UNDP, and others) have started major initiatives in the SME sector of Pakistan within the last five years. While economic development policy makers generally identify the employment potential and the number of firms as major reasons for focusing on this sector, this shift in focus has been even more profound in Pakistan.

According to SMEDA, SMEs constitute nearly 90 percent of the all business enterprises in Pakistan; employ 80 percent of the non-agricultural labor force; and their share in the national GDP is around 40 percent. A major challenge for most policy researchers in the SME area is the virtual non-existence of scientific data on this sector in the country. The only available sources of data are Census of Establishments (Government of Pakistan, 1988) and Directory of Industrial Establishments (Government of Punjab, 2002). Although much of this “official” data have serious credibility issues, some parts of it, like the number and location of establishments, is considered reliable by most standards.

The Small and Medium Enterprise Center (SMEC) at the Lahore University of Management Sciences undertook a survey in 2003 to “gauge the health” of this sector. A field survey of 651 firms in 10 national districts was conducted. These 10 districts were selected as they are home to over 50 percent of the SMEs in the country. (Census of Establishments – GoP, 1988). The survey questions focused on SME characteristics, characteristics of their owners, and the overall firm performance issues. It was aimed at identifying factors that significantly affect the health of the firm. This paper provides a summary of our key findings from the study.

In Section 2 we present the methodology; Section 3 gives the demographics/description of the data; in Section 4 key findings from the data are presented; in Section 5 we describe two of the research questions posed by the key findings (presented in the previous section) and subsequently analyzed in section 7 and 8; in Section 6 we describe the success indicators selected for the analysis and the results from the study of relationship between owner characteristics and the health of the firm; in Section 7 characteristics of better performing firms are presented.

## **2. METHODOLOGY**

The definition of SMEs vary from country to country as they are defined by a wide variety of criteria, more notably the number of employees and annual turnover. SMEs are generally considered to be non-subsidary, independent firms (OECD 2002).. Verhees and Meulenberg (2004) define a small firm as “a firm that is run and is controlled under the direct supervision of the owner.” Pakistan does not have a working definition of SMEs yet<sup>1</sup> and enterprises employing up to 99 persons constitute over 95 percent of all enterprises in the industrial sector and nearly 78 percent of non-agricultural labor forces.

---

<sup>1</sup> The Government of Pakistan has recently set up a task force to formulate a comprehensive policy for SMEs. The objectives of the task force include developing a uniform definition for SMEs in the country. <[www.pakistan.gov.pak/ministries/contentinfo](http://www.pakistan.gov.pak/ministries/contentinfo)>

For the purpose of this study, a market research firm [AcNeilson (Pakistan) Ltd] was employed for data collection because they had a well-established network for (random) data collection and quality assurance across the country. Target organizations included all manufacturing firms in the SME sector that had a total workforce in the range of 7 - 100. The market research firm conducted interviews of the executive heads (CEO, Chairman, MD, GM etc.) of target organizations and information related to different functions including finance, human resource, marketing and production, was collected. This paper is based on part of the data collected.

According to the Census of Establishments (1988), there are 72 geographic districts in Pakistan and more than 50 percent of SMEs in the country are located in the ten districts, namely: Karachi, Lahore, Faisalabad, Multan, Hyderabad, Sialkot, Gujrat, Shiekhupura, Gujranwala and Quetta. Furthermore, 25 percent of SMEs in the country were in Karachi, Lahore and Faisalabad districts. It was decided to sample 100 SMEs each, from these three districts, and 50 SMEs each from the other seven districts. The total sample size for the study was 651 firms.

Depending upon the sample size, 10 to 20 areas were randomly selected in each district of Pakistan. The market research firm conducted 5 interviews in each area. Areas were selected using the following publications; Punjab Directory of Industrial Establishments (for districts in Punjab) and the Chamber of Commerce listings, Jamal's Yellow Pages and Stock Exchange listings (for Karachi, Hyderabad and Quetta).

An area was selected by generating a random number corresponding to the page number of the specific publication. The 10<sup>th</sup> address on that page was selected. This address (and the corresponding company) gave the starting point of that area where around 5 interviews could be conducted. In case the company had moved, or become bankrupt, the surveyor would still use that address as a starting point for five interviews. If the surveyor was unable to find any SMEs (manufacturing) in the area, the market research firm replaced that area with another randomly selected area using the same technique.

### **3. SAMPLE CHARACTERISTICS**

#### **3.1 Industry Sectors**

A detailed sector-wise breakdown of the study sample of manufacturing SMEs is provided in Table I.

Table I about here

#### **3.2 Organization Size**

The survey results showed that about 50 percent (327/651 firms) of the firms had between 7 to 10 employees. SMEs having 11 to 25 employees were about 36 percent

(237/651) of the total while the firms having 26 to 96 employees were about 14 percent (87/651 firms) of the total.

### **3.3 Type of Organization**

In our survey about 61 percent firms were sole proprietorship, 29 percent firms were family partnership, 6 percent firms were non-family partnership and 4 percent of the firms were private limited.

### **3.4 Age of the Organization**

Within our data the breakup of firms (in percentages) established over the years, is as follows; about 15 percent of the SMEs were established between 2001-2003, 38 percent between 1991-2000, 26 percent from 1981-1990, 20 percent between 1947<sup>2</sup>-1990 and only 1 percent before 1947.

## **4. KEY FINDINGS**

### **4.1 SME Owner**

#### Owner as Decision Maker

According to the results of the survey, the owner runs the show at most of the SMEs. About 82 percent of the company owners are the operating heads of their companies as well. A high percentage of them (about 98 percent) handle decisions related to human resource, marketing/distribution/sales, production, finance/accounts and legal/governance issues in their companies themselves. More than 96 percent of the owners take strategic decisions themselves while 89 percent of the owners take decisions regarding day-to-day affairs, showing a high level of control.

#### Employee Profile

The average number of total employees in an SME is about 17; out of which about 98 percent are males. It is not surprising in a conservative and developing country like Pakistan, where the skill/literacy rate in women is extremely low. Note that (see Table II) the owner is the only “executive”, which further explains the key role of the owner in SMEs.

Table II about here

#### Education Level of the Owner

About one quarter of the SME owners had graduate degrees (see Figure). About 66 percent were either matric (grade 10) or above while only 8 percent of them were illiterate.

Figure about here

#### Generations in Business

---

<sup>2</sup> Pakistan came into being in 1947.

The results show that about 65 percent of the SME owners were entrepreneurs. About 28 percent of the SMEs were established by the fathers of the existing owners while the rest were setup by their grand parents or great grand parents.

#### Family Connections

A very high percentage of SME owners-operating heads belonged to families with multiple people having their own businesses. About 47 percent of the owners have relatives that own some other business.

#### Information Gathering Habits and Computer Usage

The survey results showed that a high percentage of the company owners/operating heads were regular in watching TV and reading newspapers. About 74 percent of the owners/operating heads watched television regularly (at least 2 days a week). Similarly 76 percent of them read newspapers/magazines at least twice a week. Studies by Hankinson (2000) and Hankinson, Barlett and Ducheneaut (1997) of the SMEs in UK showed that owner-managers there as well were quite regular in keeping themselves abreast of the surroundings using TV, newspapers/magazines, radio etc. As expected a low percentage (only 15 percent) of owners/operating heads of SMEs in Pakistan use computers for their office work, mostly for writing letters, e-mails, Internet, accounts/finance and making bills.

### **4.2 Human Resource**

#### Department Wise Breakup

The survey results show that human resource of the SME sector (manufacturing) in the country is concentrated in the production area. On average, there are about 16.25 employees in an SME and about 14.2 of them work in the production department. This result indicates that beside the operating head of the company there was only one other employee (on average) for all the other departmental functions. A reason for that, as stated by Hankinson (2000), could be “I have to do everything” mentality. As a result it appears that owners-operating heads in the manufacturing sector (SMEs) take care of all the other functions that is QC, Marketing, Finance, HRD, and Procurement etc.

#### Education

The survey results verified that employees working in the SME sector in the country are not that educated. About 15 employees (out of 16) are either matric (grade 10) or below.

#### Turnover

The average employee turnover was 27 percent in 2002. Out of 651 firms, 229 either did not keep any record of hiring/firing, or they were recently established. For the rest of the firms (422), average number of employees hired was 4.5, average number of employee fired was 1 and on average 3 employees themselves left the firms in 2002.

#### Training

Employees in the SME sector do not get formal training, and external training is virtually non-existent. On average, executives in about 56 percent of the firms, skilled/technical

workers in 49 percent of the firms and unskilled labour in 61 percent of the firms get no formal training at all (see Table III for details).

Table III about here

#### Performance Appraisal

The results show that human resource systems in most SMEs lack formal appraisal mechanism for their employees. In case of executives 68.5 percent, in case of skilled/technical workers 63.7 percent and in case of unskilled workers 66.4 percent of the respondents did not have any regular system of increments for their employees.

### **4.3 Markets/Contracts**

#### Sales Trends

The results of the survey show that in 2002 the performance of SMEs was generally poor; only 17 percent of the firms indicated increase in sales (18.7 percent on average) over the last year and 58 percent of the firms showed decrease in sales (34.1 percent on average). SMEs did not seem to be too optimistic about their future in 2003, as about 49.3 percent expect their sales to be stagnant, 20.9 percent expect decrease in sales (26.6 percent on average) while only 29.8 percent expect an increase in sales (22.3 percent on average).

#### Competition with Large scale Sector

Firms in the SME sector do not seem to operate in markets served by large firms (Eden, Levitas and Martinez 1997; Christensen 1997; Carson 1985). Only 3.5 percent of the firms said that their competitors had more than 100 employees (large firms). Among the rest about 58.6 percent of the firms said that their competitors have less than 15 employees and 37.9 percent said that their competitors' employees are in between 15-99.

#### Marketing Function

Market Information: According to Verhees and Meulenber [2004], in small firms "*market intelligence is based mostly on secondary data or on personal contacts*". Our analysis shows that formal systems for market data/information collection are almost non-existent in the SME sector of the country. Only 3.3 percent of the firms ever had proper marketing research conducted.

Subcontracting: The data shows that only 20 percent of the firms subcontract. For the firms that sub-contract, the percentage of cost-of-goods-sold emanating from the vendors is 24 percent of total.

Where in the Value Chain?- Out of the firms that sell in the local market, 46.3 percent firms sell their goods through wholesaler, 16.3 percent through retailer, 8.3 percent through distributor and 28.8 percent sell directly to the end user.

#### Supply Chain Management

Relationships/Partnerships: Out of 651, 159 firms (24.4 percent) sell their goods to some other manufacturer, about 80 percent (521 out of 651) sell their goods in the local market and 4.8 percent (31 out of 651) export their products. About 19 percent of total sales of the SMEs are to some other manufacturer, 75 percent of the sales are from selling goods in the open market and only 4 percent are in the forms of exports. On average about 62 percent of total sales of the SMEs were to two biggest clients (37 percent and 25 percent) and the SMEs have been in business with them since last 10 to 11 years.

The sample results indicate that SMEs purchase about 83.8 percent of their raw material from open market, 13.7 percent from some other manufacturer while only 2.5 percent is imported. Raw material purchased from open market, specific non-family source and a specific family source is on average 80.5 percent, 15.3 percent and 4.2 percent respectively.

Joint buying of raw material with competitors or with other firms in a similar line of production is almost negligible (1.06 percent of the total purchase only, in terms of rupees). Similarly the raw material purchased directly from a competing firm or from other firms involved in a similar line of production is on average 1.8 percent only (in terms of rupees).

Customers/Clients: SMEs had an average of about 25 current customers each and the average number of new customers attracted by SMEs was about 4.

#### **4.4 Productivity and Technology**

##### Machine and Technology

Each SME has about 10 machines (on average) and about 4 workers per machine. The age-wise breakup of average number of machines in SMEs is as follows: machines less than 5 years old: 2.2, 5-15 years old: 4.1 and more than 15 years old: 3.4 machines. More than 84 percent of the machinery is imported while only 16 percent is locally manufactured. The average estimated value of machinery is equal to Rs 1,187,366. The average cost of machinery as percentage of annual sales is 30 percent, indicating that on average SMEs investment on machinery is about one third of their annual sales.

##### Quality Control Procedures

Results of the survey indicate lack of formal quality control systems at most SMEs. Only 24.4 percent firms have proper quality control system, 66.9 percent of the firms perform informal quality control while no quality checking is performed by 8.7 percent of the respondents.

##### Production Cost Function

In 2002, average sales of the surveyed SMEs were Rs 4,058,725<sup>3</sup>. The sales per employee were Rs 190,793. However, the sales data was given by only 21.8 percent (142 firms) of the firms. Average expenditure (in 2002) on raw material was Rs 1,840,590, expenditure on utilities was Rs 624,292 and expenditure on labour was Rs 545,974. About 63 percent

---

<sup>3</sup> During the period of this study, the exchange rate for Pakistani rupee varied from Rs 55-60 per US dollar.

of the respondents said that the property on which the firm was built was self owned or company owned while 37 percent of the respondents had rented the property. Average price of the self or company owned land was Rs 2,628,984 and average monthly rent paid by SMEs was Rs 10,857.

#### Value Added per Employee

The average value added per employee<sup>4</sup> of the sample was Rs 39,431 (111 firms).

### **4.5 Finance/Trade Credit**

#### Investors

Results of the survey show that most of the SMEs are single person ownership firms. About 68 percent (445/651) of the firms had only 1 large investor (>10 percent share) in the company, 21 percent had 2 investors and the rest had more than two investors.

In SMEs having more than one large investor (31.6 percent of the total), about 78.7 percent of the large investors (>10 percent share) were close relatives (sibling, spouse, children or parents), 14.4 percent were non-family members and 6.8 percent were distant relatives (uncles/aunts, cousins, nephews) of the owner.

#### Short Term Loans

Only 46.5 percent (303 firms) of the firms relied on loans to arrange running finance for their business. Among the firms that take short term loan about 60 percent of their total working capital need was fulfilled through personal investment or investment through other family sources. The contribution of commercial banks was about 19 percent only.

#### Long Term Loans

Only 33.2 percent of the firms (216 firms) acquired loans for fixed/long term investment. For the firms that take loans for fixed investment about 73 percent of their long term financing needs is contributed by investment through personal and family sources while commercial banks contribute only 16 percent of the total requirement. According to Hankinson (2000) and Hankinson, Barlett and Ducheneaut (1997), SMEs in UK also tended to avoid external finance for investment purposes unless it was absolutely necessary.

#### Funds Management

Fund management practices in the SMEs sector of the country seem to be highly informal in nature. About 49.3 percent (316) of the firms have a bank account and only 43 percent of the payments received by SMEs are by way of checks. The average time since these SMEs have a bank account is nine and half years. Unbiased audits are conducted by only 15.8 percent of the firms to evaluate the financial situation of their firm. Average time since these firms have been conducting unbiased audits is almost 9 years.

#### Planned Investment in Equipment and Machines

---

<sup>4</sup> (Sales – Expenditure on raw material – Expenditure on utilities)/Total number of employees

About 79 percent (513) of the SMEs have no intention of making any investment on fixed assets other than building). Out of those who intend to make any investment in the future on fixed assets (other than building); 126 firms are planning to invest Rs 770,238 in 2003 (on average) while 101 firms are planning to invest Rs 1,886,782 (on average) in 2004-2006.

The firms that are not interested to make any new future investment are about 56 percent of the total. About 14 percent of the firms cited expensive inputs, 13 percent of the firms cited expensive utilities/electricity and 10 percent of the firms cited expensive labour as the foremost reason for not making any new future investment.

#### Ease of Obtaining Bank Loans and Rates Charged

The SMEs think they will have to pay annual interest on loan of about 10.7 percent to the banks. The respondents also feel that on average it will take 84 days to get the loan after the application. About 59 percent of the respondents think that they will have to show personal land / money as security for the loan while 38 percent think that assets of the company will act as security for the loan.

#### **4.6 Governance**

For giving a boost to their businesses 29 percent of the firms wanted reduction in electricity/utility charges and about 13 percent said that taxes should be reduced.

According to 51.8 percent SMEs, tax department was among three government organizations with whom the owner/operating head had to spend maximum amount of time and 46.1 percent SMEs said that WAPDA<sup>5</sup> was among three government organizations with whom the owner/operating head have to spend maximum amount of time.

Responding to the question on ways to improve SMEs health, 29 percent of the respondents said the government should reduce the electricity/utility rates, 13.2 percent said that the taxes must be reduced/removed, 7.8 percent said that loans must be given to small businessmen, 5.6 percent said that loans should be given on low markup rate and 4.3 percent said that the price of raw materials should be reduced.

#### **5. RESEARCH QUESTIONS STUDIED**

The descriptive presented in the previous section provided interesting insights that were used to explore answers to two questions;

- 1- Owner Characteristics and the Health of Small and Medium Enterprise: One of the important finding of the study was that firms in the SME sector of the country in general revolve around the owner/entrepreneur. About two thirds of the owners were the entrepreneurs as they themselves setup the business. More than two thirds of the SMEs in the country were single ownership firms. Among the rest

---

<sup>5</sup> Water and Power Development Authority is the national utility company.

about three fourth were family (close relatives) partnership firms. About two thirds of the company owners do business on their own property. Hence an interesting follow-up question was; what characteristics/traits of the owner have a significant correlation with performance in the SME sector?

- 2- Characteristics of Successful SMEs: Another pattern quite obvious from the data was that most of the SMEs do not have formal HR, quality control, marketing and finance systems in place. Only 50 percent of the SMEs had bank accounts. About 5 percent were into exports. There is limited long-term relationship building with the suppliers. Thus another interesting follow-up question was ‘what company/business characteristics have a significant relationship with performance?’

## 5.1 Performance Indicators

SMEs in Pakistan (like in most developing countries) are quite wary of sharing data on sales or profitability with any stranger. In our pre-testing of the questionnaire very few firms gave any response to the question on pre-tax profits. Hence it was decided to drop this question from the survey. However, a number of other questions were included that give a similar indication of a firms performance. Out of those, three performance parameters: sale per employee, increase/decrease in sales over the last year and investment plans on fixed assets (other than building) next year, were selected as indicators of a firm’s performance. These parameters were a) the most comprehensive in the whole list, and b) had enough data size.

### Sales Increase/Decrease

For our analysis we defined better performing firms as those having greater than or equal to 10 percent (74 firms) increase in sales (in 2002) over the last year. Low performing firms were defined as those whose sales showed greater than or equal to 20 percent decline (278 firms) in sales. The total sample size constituted of 352 firms. This variable is a measure of growth/expansion of the firm. A problem with this measure is that many companies might not have reported an increase in sales (although we had not asked them for the exact amount) out of mistrust for the surveyor.

### Sales/Employee

We had sale per employee figures (Rs) for 142<sup>6</sup> firms (21.8 percent firms). The average sale per employee for these 142 firms was Rs 190,793. For our analysis an SME was considered healthy if its sale per employee was more than Rs 190,793. This variable measures the efficiency of the firm. A problem with this measure is that a company can have higher sales/employee and still be non-profitable.

### Investment Plans

---

<sup>6</sup> We used sales per employee as one of the health indicators although we had a response rate of only 21.8 percent. However, the readers should not expect a bias as we compared the average number of employees for the firms who gave their sales figures (Mean 16.26: SD 16.3) with those who did not (Mean 17.96: SD 14.66). As seen from above numbers the results were not much different

The response rate to this question was 99.2 percent. About 15.3 percent firms intend to make investment on fixed assets (other than building), while the rest (547 firms: 84.7 percent) do not intend to make any investment. Investment plans were assumed to be a measure of owner's confidence in the firm's future; the authors recognize that at times firms make investments even when the current performance is not good.

## **6. OWNER CHARACTERISTICS AND HEALTH OF THE FIRM**

While this topic has been studied for employees in the large-scale sector in Pakistan (Raja 2004), similar studies has not been done on the SME sector. In the United Kingdom work has been done by Hankinson (2000) to identify key factors in the profiles of small manufacturing firm owner-managers. A similar study by Hankinson et al. (1997) also identifies key factors in the profiles of small-medium enterprise owner-managers. However, both these studies ran short of identifying key factors in the owner characteristics of high performing firms. We segregated the better performing firms from the low performing firms, on the basis of the health indicators. Then we analyzed (using statistical tests) how the different personal characteristics of the owner/manager of the better performing firms were from those of the low performing firms. At the onset, it was hypothesized that ownership/manager factors such as the education level, their ability to use technology, and being an informed owner have a direct impact on the health (performance) of the firm. Sales/employee, increase/decrease in sales, and investment plans of the firm were taken as surrogates for the health of the firm.

### **6.1 Performance/Health Indicators Vs Owner Personality**

As stated earlier, analysis was done between the three health indicators (increase/decrease in sales over the last year, sale per employee and plans of making investments on fixed assets, other than building, in 2003) and different characteristics of the owner. A summary of significant results is given in Table IV.

Table IV about here

Based on literature review as cited above, and the analysis of data gathered during our research the following hypothesis were developed and subsequently tested.

Hypothesis 1: (Education) Firms which show better performance have better educated owners.

Hypothesis 2: (Family Ownership and Business Connections) Owners of the firms showing better performance are better connected than others.

Hypothesis 3: (Using Computers for Office Work) The use of computers by owners/mangers is more common among better performing firms.

Hypothesis 4: (Watching TV and Reading Newspapers/Magazines) Owners/managers with above average firm performance are better informed than others.

Hypothesis 5: (Number of Large Investors) Number of investors has an impact on the health of the firm.

## 6.2 Results

The results showed that education, media related habits, use of information technology, number of investors and generations in business have a significant relationship with the health of the firm.

Results by testing hypothesis 2 were quite interesting. It is generally believed that people in “business families” have a better chance at doing well in business. Our survey showed that 67 percent of the respondents were entrepreneurs (first generation in business). The health indicator of sales per employee showed that the SMEs setup by the fathers of the existing owners have performed better in 2002 while according to the health indicator of increase/decrease in sales, the SMEs setup by the fathers and grandfathers of the existing owners performed better. Sales per employee is basically a measure of a firm’s efficiency while increase/decrease in sales is a measure of a firm’s growth. The results suggest that an entrepreneur is basically involved in business growth; he does not focus on efficiency. The second generation in business has to prove itself to the family, so they focus on business consolidation and efficiency improvement. For the third generation (in business) business expansion again becomes the center of attention, as the business actually might have shrunk during the years their fathers were running the businesses.

Results from hypothesis 5 suggested that firms owned by two investors were more efficient in 2002 as compared to single ownership firms or firms having more than two owners. Thus collaborating with another partner seems to have a positive impact on a firm’s performance in the SME sector. On the other hand, the performance of SMEs owned by three or more investors was poor (indicated by health indicators of sales per employee and plans of investment). Hence it seems “too many cooks spoil the broth” in the SME sector.

A relationship could not be established between the health indicators and caste (ethnic background) of the owner, owner’s relatives’ occupation, and whether the relatives of the owner owned some other business or not.

## 7. CHARACTERISTICS OF SUCCESSFUL FIRMS

Based on the descriptive data presented in section 3, the authors also analyzed the characteristics of successful SMEs. At the onset it was postulated that SMEs having formal HR, Marketing, Quality Control and Financial systems in place would show better performance as compared to others. The health indicators used for the study were sales increase/decrease, sales per employee and investment plans on fixed assets other than building (see Section 5 for details). Analysis was done between these three health indicators and different characteristics of the firm. A summary of significant results is provided in Table V.

Table V about here

## **7.1 Hypothesis Tested**

Hypothesis 1: Firms that show better performance have formal HR systems in place. The literature in the field of HRM emphasizes the importance of well-motivated, highly skilled work force as a determinant of a small business's ability to remain competitive (Hodgetts and Kuratko, 2001; Longenecker, Moore, and Petty, 2000). Our results also showed that regular system of increments for employees and formal training programs for skilled/technical workforce have significant positive relationship with the performance of SMEs.

Hypothesis 2: Firms that show better performance conduct proper marketing research. Proper marketing research was conducted by only 3.3 percent of the respondents; thus the sample size was too small to show statistically significant relationship with performance.

Hypothesis 3: Firms that show better performance have Quality Control procedures in place.

Formal Quality Control procedures showed a positive relationship with the health of the firms.

Hypothesis 4: Firms that show better performance have formal financial systems in place. Having bank accounts, conduction of un-biased audits and a high percentage of payments being made through checks (as opposed to cash) showed positive relationship with the health of a firm.

The results also showed a positive relationship between firm size and performance. One interpretation could be that greater the firm size more is the need to have formal systems in place.

Hypothesis 5: There is positive relationship between performance and exports. Our results showed that better performing firms exported a significantly higher percentage of goods as compared to others.

Hypothesis 6: Firms that show better performance have partnerships

We also observed a positive relationship between firm performance (as indicated by the health indicator of investment plans) and sub-contacting. Positive relationship was also seen between the investment plans of a firm and purchase of raw material from specific source.

Hypothesis 7: Firms that show better performance have better machinery

The results showed that better performing SMEs had newer machines and a high percentage of machinery was imported. According to Berry, Rodriguez, and Sandee (2001) technological upgrading (which also includes better machinery) is one of the mechanisms for raising productivity.

Comparatively more efficient firms had more number of machines and consequently significantly higher value of machinery.

Hypothesis 8: Multi-product SMEs show better performance

The results showed that better performing firms offered/produced a larger number of products. This result points towards the concept of economies of scope achieved by the multi-product enterprises (Panzar and Willig, 1981).

## **7.2 Other Findings**

The analysis showed that price of land on which the SMEs were built was more for better performing firms. It needs to be tested but this result might be indicating that efficient firms are in 'clusters' thus the price of land on which they are built is relatively higher.

The better performing firms had a larger number of customers and a higher percentage of them competed with medium sized firms.

Table VI shows the relationship between the performance of a firm and the selling channel of the firms selling in local market (and not to original equipment manufacturers).

Table VI about here

When we analyzed firm performance in terms of percentage of goods sold to wholesaler/distributor and retailer/end user we observed seemingly conflicting relationships for the three success criterion. Growing firms ( $\geq 10\%$  increase in sales) and expanding firms (having plans of investment in 2003) sell more to the retailer/end user (56% and 64% of their sales in local market) while efficient firms (above average sales per employee) sell more to the wholesaler/distributor (63% of their sales in local market). These results show that owners of SMEs focusing on growth and having plans of investment are more market oriented, that is, a high percentage of their sales are directly to the retailer/end user; while firm owners focusing on efficiency are more operations oriented and a high percentage of sales are through wholesaler/distributor.

## 8. CONCLUSION

The SME Pulse survey is the first attempt in Pakistan to collect scientific data on the SME sector. An important finding of the study was that firms in the SME sector of the country in general revolve around the owner/entrepreneur. About two thirds of the owners were the entrepreneurs as they themselves setup the business. More than two thirds of the SMEs in the country were single ownership firms. Based on these results hypothesis were developed to analyze what characteristics/traits of the owner have a significant correlation with performance in this sector. The results showed that owners' education, media related habits, use of information technology, number of investors and generations in business have a significant relationship with the health of the firm.

The results also showed that SMEs' total investment on equipment/machinery is only about one third of their annual sales. Most of the SMEs do not have formal HR, quality control, marketing and finance systems in place. Only one half of the SMEs had bank accounts. About 5% were into exports. Hence another interesting question studied was what company characteristics have a significant relationship with performance? Our results show positive relationship between firms' performance and whether or not they have formal HR, QC and financial systems in place. Some of the other factors that showed significant relationship with SME performance were percentage of goods exported, number of products produced, number of customers, amount of sub-contracting and whether or not they had better machinery.

Lastly, various indicators suggest an overall negative trend in performance within the SME sector warranting the need for in-depth study for the underlying causes for a decline in this key sector of Pakistan's economy.

# **TURNAROUND STRATEGIES FOR DECLINING ENTREPRENEURIAL FIRMS: THE EFFECTS OF PERFORMANCE AND RESOURCES**

## **ABSTRACT**

Growth has been described as the essence of entrepreneurship. Organizational ecologists theorize an inevitable progression from growth through maturity, revival, and eventually decline. During the organizational life cycle entrepreneurs choose between growth, stability, or retrenchment strategies to overcome deteriorating trends in performance. Using survey data, this study tests a contingency model of strategic choice for declining entrepreneurial firms in the U.S. Small Business Administration database. The results indicate entrepreneurs choose growth strategy when their perceptions of resource availability and past financial performance are both high and when both are low, indicating entrepreneurs remain aggressive when faced with adverse conditions.

## INTRODUCTION

Many firms experience deteriorating financial performance resulting from market erosion and maladaptive decisions by management. Managers respond by selecting corporate strategies that redirect their attempt to improve their firm's competitive position. Previous literature has described strategic choice employed by declining firms to reverse negative trends of performance as turnaround strategies (O'Neill, 1983; Pant, 1991; Pearce and Robinson, 1992). Turnaround strategy is a form of retrenchment strategy which focuses on operational improvement when the state of decline is not severe. Other possible corporate level strategic responses to decline include growth and stability. Exploring other options is particularly important for entrepreneurial firms because of their predisposition to growth and innovation. Managers' strategic responses are often contingent on internal and external factors that are historical and anticipated. Researchers have developed and tested several theories on the significant factors affecting strategic responses by managers in declining multinational corporations. Tan and See (2004) suggested that strategic choice is a function of organizational slack, size, and management's perception of external factors controllability. One of the more prominent historical factors affecting strategic choice is the severity of the financial deterioration (Hofer, 1980; Robbins & Pearce, 1992). Researchers have also established a link between corporate diversification strategy and resource constraints, but the contingent effects of the level of deterioration and limits to resource availability on strategic choice have not been addressed adequately (Penrose, 1959; Ackoff, 1970; Hofer and Schendel, 1978; Hitt and Ireland, 1985; and Wernerfelt, 1984).

The current study extends previous research by proposing and testing a contingency model that suggests the likelihood that entrepreneurs will choose growth or retrenchment

strategies when faced with deteriorating performance depends on their perception of resource availability and historical financial performance. This paper first discusses literature related to decline, corporate strategy, and resource-based theory. Next, hypotheses are presented and tested for the effects of performance and resource on strategic choices. The findings should help entrepreneurs understand at which combined levels of historical performance and resource availability are growth, retrenchment, or stability strategies most appropriate.

## **LITERATURE REVIEW**

Two basic theories have dominated the management literature on organization failure. A deterministic perspective in classical industrial organization and organization ecology literature suggests that managers are constrained by exogenous industrial and environmental constraints and therefore their strategic choices have limited impact. A more voluntaristic perspective in organization studies and organizational psychology literature suggests that managers' actions and perceptions are the fundamental cause of organizational failure (Mellahi & Wilkinson, 2004).

From the ecological perspective Cameron, Sutton, and Whetten (1988) described organizational decline as a two stage phenomenon. The first stage of decline occurs when an organization's adaptation to its domain or microniche<sup>1</sup> deteriorates. The second stage occurs when the organization's financial and human resources begin to diminish. Both stages of decline indicate that the organization has become less adapted to its microniche and is less successful at exchanging its outputs for new inputs. Weitzel and Jonsson (1989) characterized decline as the opposite of successful adaptation to the environment. They suggested that organizations enter the state of decline when they fail to anticipate, recognize, avoid, neutralize,

---

<sup>1</sup> Microniche is defined by Cameron, Sutton, and Whetten (1988) as the product or market domain of the firm.

or adapt to external or internal pressures that threaten the organization's long-term survival. Additionally, Levy (1986) defined decline as the inability of the decision makers to heed the warning signals of the need for change. For the purpose of this paper, decline is defined as a trend of deteriorating financial performance.

According to population ecologists, strategic decisions differ as the company evolves through the stages of the organizational life cycle (Hanks, 1990). Entrepreneurs focus on survival during the start-up phase, and their strategy is limited to making their product or service innovation successful. During the growth phase entrepreneurs adopt competitive strategies that can require retrenchment. In the decline stage growth is negative, products are obsolete or have limited potential, and the organization is inefficient or bureaucratic. Decline is often preceded by ineffective or short-lived attempts at revival where entrepreneurs focus on internal changes that can be made by reallocating limited resources (Holt, 1992).

Research from the voluntaristic perspective suggests that managers make distinctive choices. Tan and See (2004) identified two main strategies taken in a declining Asian manufacturing industry: offensive strategic reorientation and defensive strategic shift. They found that firms adopting defensive strategic shift attributed decline to uncontrollable factors, are under greater severity of decline, have a lower level of slack and are smaller in size (Tan & See, 2004). Mone, McKinley, & Barker (1998) offered a contingency framework that predicted a firm responds either innovatively or conservatively to decline, based on constraints on an organization's capacity.

The strategic response to decline is expected to differ for entrepreneurial firms for a number of reasons. Although there are no indisputable definitions of entrepreneurship, one common denominator is that entrepreneurs create incremental wealth and assume major risks in

terms of equity, time, and career commitment (Ronstadt, 1984). Because they have assumed a personal risk, they are likely to have a different strategic response than the manager of a multinational firm when faced with the loss of their life savings as well as their reputation. Also entrepreneurs tend to be leaders who are emotionally involved in a venture, think strategically to create opportunities, and provide the inspiration for sustained momentum (Holt, 1992). Asian firms of varied size, often function as owner-managed, and are given more discretion and are more inclined to debt financing, even as the firm grows into publicly-held ownership (Burton, Ahlstrom, & Wan, 2003).

According to the theory of disequilibrium and chaos, entrepreneurs periodically introduce innovation, thereby creating disequilibrium (Stevenson & Harmeling, 1990). In the decline stage, they often have difficult transitioning from the visionary and aggressive competitor role of founder to the role of professional turnaround managers. When faced with the reality that the failure may be attributable to their poor management, they may resort to the more familiar aggressive role of innovator (Bruno & Leidecker, 1988). If they fail to make the transformation, either the venture suffocates or the entrepreneur does not survive the organizational evolution (Holt, 1992). A more recent study (McCarthy, 2003) suggested that the experience of crisis gave rise to a more rational, planned approach to the strategy-making process.

The other difference for entrepreneurial firms, when compared to large diversified corporations, is financial resource limitations. Strategic alternatives available to small firms are limited to internal changes that are made through the reallocation of limited resources. Despite resource constraints, however, entrepreneurs still tend to focus on growth and diversification. Growth through diversification, tends to preoccupy entrepreneurs, despite lack of evidence to suggest it is a successful strategy in the decline stage. From their perspective, growth may be

necessary to establish an image, increase the firm's asset base, meet competition, improve profits, satisfy the founder's need to head a large organization, or has become essential for survival (Holt, 1992).

Most prior research in the strategic management literature has focused on turnaround strategy when firms are in decline (Schendel, Patton, and Riggs, 1976; Hofer, 1980; Hambrick and Schechter, 1983; O'Neill, 1983; Pant, 1991; Pearce and Robinson, 1992). According to Wheelen and Hunger (2001) turnaround strategies are a form of retrenchment that emphasize the improvement of operational efficiency. The two principal types of turnaround strategies, contraction and consolidation, are used when a corporation's problems are not pervasive. However, researchers have largely ignored the possibility that firms may choose a growth strategy or stability strategy when experiencing declining performance.

The most common growth strategies are diversification at the corporate level and concentration at the business level (Wheelen & Hunger, 2001). Ramanujam and Varadarajan (1989) defined diversification as the entry of a firm into new lines of activity, through internal development or acquisition. Internal development can take the form of investments in new products, services, customer segments, or geographic markets including international expansion. Diversification can also be accomplished through external modes such as acquisitions and joint ventures. Concentration can be achieved through vertical or horizontal growth. Vertical growth occurs when a firm takes over a function previously provided by a supplier or a distributor. Horizontal growth occurs when the firm expands products into new geographic areas or increases the range of products and services in current markets. Much of the empirical research for large firms has focused on diversification strategy, however.

Previous researchers have established a linkage between decline and diversification by suggesting that poor financial performance affects the choice of diversification strategy. Burgelman (1983) maintained that the creation of new ventures is often stimulated by deteriorating performance in existing businesses. Ramanujam and Varadarajan (1989) also suggested that a diversification strategy is a likely response to poor financial performance.

International geographical diversification has also been linked to strategic choice for small firms in difficulty. Specifically, firms that are already involved in foreign business will grow internationally in response to declining performance (Chen & Martin, 2001). Tan and See (2004) proposed that firms with organization slack will choose a more offensive strategic orientation.

Prior studies have proposed that strategic choice for declining firms is contingent upon past financial performance trends. For example, firms substantially below financial break-even may initiate asset reduction strategies, while firms operating near break-even may implement revenue generation or cost reduction strategies (Hofer, 1980). Robbins and Pearce (1992) also linked strategic choice for declining firms to financial performance. They suggested that as severity of decline increased, retrenchment strategies should progress from cost reduction to asset reduction strategies. Consequently, this paper proposes the following:

H1: Perceptions of past financial performance influence small firms' choice between growth and retrenchment strategies.

The resource-based view of strategic management has received a great deal of attention recently as a perspective for understanding firm growth. Penrose (1959) established the conceptual foundation of the resource-based theory of the firm, maintaining that resource constraints are a limitation to growth created by the need to balance goodwill, excess capacity and organizational slack. The growth of the firm is limited only in the long run by its internal management resources (Penrose, 1959). Total managerial services that a firm requires at a point in time are partly constrained by the necessity to run the firm at its current size. Additionally, it is partly constrained by the requirements for expansionary ventures (Mahoney & Pandian, 1992). Although new managerial recruits increase the growth potential of a firm, training new managers and their integration into the work force occupies the time and effort of existing managers and thus temporarily reduces the managerial services available for expansion.

Resource availability has been suggested as a predictor of strategy choice, particularly in regards to diversification (Penrose, 1959; Ackoff, 1970; Hofer & Schendel, 1978; Hitt & Ireland, 1985; and Wernerfelt, 1984). The traditional concept of strategy suggests organizations establish competitive advantage by effectively evaluating their resources and focusing those resources on the generation of rent<sup>2</sup> (Andrews, 1971 & Ansoff, 1965). Therefore, it is the resources of the firm that limit market choice and profit expectations (Wernerfelt, 1989).

Penrose (1950) classified resources into the following: land and equipment; labor (including worker's capabilities and knowledge); and capital (organizational, tangible, and intangible). Subsequent research by Hofer and Schendel (1978) suggested that a firm's resource profile combines the following resources and capabilities: (1) financial resources (e.g., cash flow, debt capacity, new equity availability); (2) physical resources (e.g. plant and equipment, inventories); (3) human resources (e.g. scientists, production supervisors, sales personnel); (4) organizational resources (e.g. quality control systems, corporate culture, relationships); (5) technological capabilities (e.g. high quality production, low cost plants). Grant (1991) later added a sixth type of resource, intangible resources (e.g. reputation, brand recognition, goodwill). Since it is expected that growth strategies require resources for execution, the following hypothesis is offered:

H2: Perceptions of resource availability influence small firms' choice between growth and retrenchment strategies.

In addition to this link between resources and growth strategies, resource constraints have been associated with poor financial performance among publicly-traded firms. D'Aveni (1989) linked decline and resources by defining decline as a pattern of decrease over time in a firm's financial and managerial resources. He concluded that firms may delay or avoid bankruptcy by adopting a growth strategy to support a resource deficient firm. In other words, the strategy choice of a firm with poor financial performance is dependent upon the availability

---

<sup>2</sup> Rent is defined as return in excess of a resource owner's opportunity costs (Tollison, 1982).

of resources. Chen & Martin (2001) found that the propensity to diversify internationally was contingent on managerial resources specific to foreign experience. As mentioned before, an entrepreneur's strategic alternatives are limited by the availability of resources, thereby precluding some complex strategic alliances or large acquisitions. It can also be concluded that the result of a trend in poor financial performance is resource constraints. Therefore, this study proposes a joint effect of resource constraints and financial performance on strategic choice as follows:

- H3: The perceptions of resource availability will moderate the effect of perceptions of past performance on small firms' choice between growth and retrenchment.

## **METHODOLOGY**

### **Sample**

The sample for this research was derived from the United States Small Business Administration's (SBA) database of small businesses that contract with U.S. federal agencies. Firms included in the database conform to the small business standards of the SBA for their respective Standard Industrial Classification Code.

A questionnaire was developed and tested using a pilot study of ten entrepreneurs, and revised based on their feedback. The questionnaire was then randomly distributed to 400 firms in the database with a cover letter to introduce entrepreneurs to the purpose of the study and assure confidentiality. Using a basic definition of an entrepreneur as one who creates incremental wealth and assumes major risks (Ronstadt, 1984) respondents were included in the survey if they were a founder, as well as a current majority owner and a primary manager, based on a survey question. There were 138 complete and usable instruments returned for an acceptable response rate (34%) for limiting the effects of selection error (Yu & Cooper, 1983). The sample was further stratified by considering only firms that indicated their most

recent performance period was stagnant or declining, resulting in a final sample of 88 firms. The final sample was compared to the 50 firms eliminated from the study, finding no significant differences in terms of size or industry. As categorized in the database, the proportion of respondents by industry were as follows: professional service (22%), non-professional service (23%), construction (17%), commodities (14%) , and manufacturing (24%). The average size in terms of employees was 35.

### **Measurement of variables**

Consistent with McDougall and Round (1984), strategic choice was measured on a binary basis, as growth or retrenchment strategy anticipated during the next twelve month period of performance. Strategy was coded “1” when they chose a growth strategy (acquiring another company, establishing a new market, or joint venturing with another company). Strategy was coded “0” when they chose a retrenchment strategy (turnaround, divestment, or liquidation), (Wheelen & Hunger, 2001). The 20 firms choosing stability were eliminated from the study to ensure better interpretation of the results.

Limited theory exists for developing a measurement scale for manager’s perceptions of resource availability. Although objectives measures are more popular, Venkatraman and Ramanujam (1986) found a high degree of correlation between perceptual and objective performance measures and concluded that perceptual measures are acceptable operationalizations of business economic performance. Therefore, this paper measures resource availability based on entrepreneur’s perceptions. In keeping with Hofer and Schendel (1978) and D'Aveni (1989), the resources considered were: (1) availability of debt financing; (2) availability of equity financing; and (3) availability of labor. Response options were coded on a Likert-like scale of 1 to 5, with “1” being not very available to “5 being very available. A Cronbach alpha (coefficient = .73) calculated the internal consistency estimates of reliability for the four items and their relationship to the resource availability factor. The

sum of the scores for the three items represents the degree of resource availability perceived by the entrepreneur, with scores ranging from 3 to 15.

Financial performance was measured by asking the respondent whether sales and profits increased, remained the same, or decreased each year over the past three years. Again, perceptual measures are an acceptable substitute for objective measures of economic performance (Venkatraman & Ramanujam, 1986). For both measures of performance—sales and profit—an upward trend was coded three (3), a stagnant trend was coded two (2), and a deteriorating trend was coded one (1). A Cronbach alpha (coefficient = .83) calculated the internal consistency estimates of reliability for the six items and their relation to the performance factor. The scores were summed for sales and profit trends for each year over the three year period, resulting in a potential range of 6 to 18.

Size and industry are often used as control variables to limit confounding effects. In this sample the effects of size are limited since all firms are classified as small in their respective industry. Research indicates that the change in total market sales may have an impact on business difficulties (Chen & Martin, 2001). In this study, industry effects are limited because firms in the sample derive an average of 28% of revenue from U.S. Federal Government procurement, and are therefore not included as a control variables.

### **Analysis**

Since the dependent variable, strategic choice was measured dichotomously (growth or non-growth), a hierarchical logistic regression model was used to determine if resource availability and financial performance have a joint influence on strategic choice. The following logistic regression equation (in linear form) suggests the relationship of the variables tested in the preceding hypotheses.

(a) Strategic Choice =

$$a + \beta_1 \text{ Resource availability (R)} + \beta_2 \text{ Financial Performance (P)} + \beta_3 \text{ R*P} + e$$

In this model, strategic choice represents a positive binary variable of growth or retrenchment. The signs of the parameter estimates are expected to be positive for the main effects and the interaction term.

## RESULTS

Table 1 provides means, standard deviations, and correlations for the variables used in this study. An analysis of the data indicates that none of the variables exceeded acceptable thresholds for skewness (2.0) and variance inflations factors (10.0) suggesting no problems with normality of data or multicollinearity that would violate assumptions for the general linear model (Lomax, 1992).

-----  
insert Table 1  
-----

Table 2 shows logistic regression analysis results for the full and reduced models.

-----  
insert Table 2  
-----

In the reduced model, the perception of financial performance coefficient is not significant and the perception of resource availability coefficient is negatively significant ( $p < .05$ ) and large, relative to its standard error. The full model includes the main effects as well as the interactive term, which is a cross-product of financial performance and resource availability perceptions. In the full model, the main effects coefficients are negatively significant ( $p < .05$ ) and large in relation to its standard errors. The results support Hypothesis 3, which proposes that the interaction of financial performance and resource availability perceptions significantly impacts the selection between a growth or retrenchment strategy. In moderated regression equations, a significant interaction term indicates that two or more lines fit the data better than a single regression line. This is demonstrated in Figure 1, since the slope of the curve is not zero.

-----  
insert Figure 1  
-----

In linear regression the  $R^2$  would indicate the additional variance explained by the interaction term. This analysis calculates a pseudo  $R^2$  in keeping with Aldrich and Nelson (1984). The interpretation of a pseudo  $R^2$  is similar to the traditional  $R^2$ , providing a measure of the quality of fit for the model. The change in  $R^2$  (.0318) between the reduced and full models is significant ( $p < .05$ ), indicating that the interaction term adds significantly to the explanation of strategic choice.

Since there is a significant relationship between the moderator (resources) and both the predictor (performance) and dependent variable (strategy), the model is a quasi-moderating relationship (McArthur & Nystrom, 1991). In other words, resources moderate the form of the relationship but not the strength. In addition to the interpretation of the sign of the interaction, the form of the interaction can also be interpreted. A series of simple regression models were created by entering different values for the moderating variable, resource, in the interactive multiple regression models (Simerly & Li, 2000). Using Cohen and Cohen's (1983) guidelines, one standard deviation above, at, and below the means were used as the high, medium, and low values, respectively, to plot the interactive effects of resources and performance with respect to strategy. Substituting a range of low-low to high-high response values of performance and resource availability into the unstandardized regression equation, a symmetrical curve results, suggesting that firms are likely to choose a growth strategy at very low and very high levels of combined financial performance and resource availability (Figure 1). Specifically, the graph indicates that firms with low performance perceptions (1 through 3) and low resources ("1" on the x axis) will choose a growth strategy (above 1 on the y axis). As resources increase with respect to low performance perceptions (2-3), the likelihood of choosing a growth strategy diminishes. When performance perception is moderate (4-6) the slope nears zero, indicating limited preference for either growth or retrenchment. When performance perceptions are high (7-9) the likelihood of choosing a growth strategy increases as resource perceptions increase (7-

9). Specifically, firms with high resource and performance perceptions are likely to choose a growth strategy (9).

## **DISCUSSION AND CONCLUSION**

The purpose of this study is to develop a contingent perspective of strategic choice for small entrepreneurial firms in decline. The results indicate the choice between growth and retrenchment strategies depends on the interaction between perceived performance and resource availability. Specifically, entrepreneurs are likely to choose growth if they perceive high levels of past financial performance and perceive that resources are available to support their strategic plan. The symmetrical nature of the interaction of the main effects suggest an interesting phenomenon, however. Firms are also likely to choose a growth strategy if they perceive a very low combination of financial performance perception and resources availability. Although counter intuitive, this supports previous findings that entrepreneurs remain aggressive in their strategy choice, even when performance and resources are poor (Staw, Sandelands, & Dutton, 1983). Small business owners, by definition are risk takers, and may see growth as their only alternative to severe decline. These results support D'Aveni's (1989) finding among public firms that resource deficient firms near bankruptcy choose growth strategies. These findings also support Burgelman's (1983) contention that deteriorating performance stimulates efforts to create new ventures. Similarly, diversification strategists have suggested a curvilinear relationship between the relatedness of diversification and performance. If a firm allocates new resources and capabilities to a similar business, the likelihood of performance improvement is increased (Wheelen & Hunger, 2001).

One possible limitation of this study is the representativeness of this sample of entrepreneurs which contract with U.S. federal agencies. Since the study did not control for the

degree of public versus commercial market base, this study may not be generalizable to all firms. Secondly, this research does not consider the success of implementing a growth strategy as a response to financial decline. Future research could examine the effects of trends on the strategic choice of entrepreneurial firms in decline using objective financial data, although it is difficult to obtain from privately-held companies. Also, limiting strategic choice to a dichotomy improves the interpretability but lessens our understanding of stability strategy as a discrete choice. Although not directly measured as part of the dependent variable, Figure 1 suggests that firms with moderate performance perceptions (4-6) may choose stability strategies which are implicitly represented by zero on the y axis. Finally, using only declining firms and eliminating firms choosing stability strategies reduced the sample, but the power was still sufficient for a study of this nature (Cohen & Cohen, 1983). Although a mean difference comparison between declining firms and the non-declining firms related to strategy choice did not produce significant results, future research may investigate why not.

In conclusion, this study suggests there is merit to analyzing how strategic variables interact in periods of decline. It also should encourage the use of a resource-based approach for predicting how entrepreneurs respond to deteriorating financial performance. Although decline is not always the most popular subject, understanding the context of aggressive or passive strategic choices should help explain the behavior of entrepreneurs, when things get tough.

# INTEGRATING MARKET KNOWLEDGE INTO R&D – TYPOLOGY OF CHALLENGES IN YOUNG BIOTECHNOLOGY FIRMS

Maija Renko

Florida International University, College of Business, RB 230, 11200 SW 8<sup>th</sup> Street, Miami FL 33199. Tel: 305 348 7156. E-mail: [maija.renko@fiu.edu](mailto:maija.renko@fiu.edu).

## ABSTRACT

Inspired by technology management literature and Austrian economics view on entrepreneurial opportunity discovery, this study looks at the dissemination of market knowledge in young technology ventures. Austrian economic theories emphasize the role of idiosyncratic knowledge, especially market knowledge, in entrepreneurial opportunity discovery. Also, previous research has directed attention to the importance of customer knowledge in research and development (R&D). However, little is known about processes employed by small and young technology firms to disseminate market knowledge within firm and to integrate market knowledge into their research and development efforts. This study addresses the research gap with a qualitative research approach. Based on interviews conducted in 85 research intensive, small, young biotechnology ventures in the USA and in Northern Europe, challenges that these firms face in integrating market knowledge into their R&D operations are identified. Even though most of the challenges are identified on the firm level, some of them reflect peculiarities of the biotechnological product development (industry level) or interaction between scientists and business people (individual level). The results suggest that technology ventures face challenges in integrating market knowledge into R&D because of (1) excessive focus on technology instead of e.g. asking future end users of products for their opinions on product features; (2) excessive focus on meeting development milestones instead of visioning end products in the markets one day; (3) forgetting the development of internal communication channels especially in the times of rapid growth; (4) failing to understand the different goals and mental models of scientists vs. business people.

## INTRODUCTION

As economic growth is increasingly driven by knowledge intensive industries, academics have become increasingly interested in the role that knowledge plays in the innovation process as well as in entrepreneurial opportunity discovery. According to Hammond and Summers (1972), knowledge reflects the extent of a subject's accurate detection of a task's properties. Thus, a manager who can correctly identify customer preferences and competitors is deemed knowledgeable about customer preferences and competitors (Marinova 2004). Day and Nedungadi (1994, p. 32) note that "the two most salient features of a competitive market are customers and competitors." When delineating the domain of market orientation construct, Narver and Slater (1990) build on customer knowledge, competitor knowledge, and interfunctional coordination. In this research, the term "market knowledge" implies knowledge about customers and competitors.

The purpose of the current study is to identify the bottlenecks that hinder market knowledge dissemination in high technology SMEs. More specifically, the focus is on integrating market

knowledge into R&D. Based on a qualitative research approach, I develop a typology of barriers that prevent this intelligence dissemination.

## **THE IMPORTANCE OF MARKET KNOWLEDGE FOR NEW VENTURES**

Austrian theories emphasize the role of idiosyncratic information in entrepreneurial behavior, especially in opportunity discovery (Hayek 1945; Shane 2000, Denrell et al. 2003). Seeking information, investing in human capital, and systematically searching through promising ideas are not entrepreneurial acts in themselves, but they can create an environment where entrepreneurial insights are more likely to be generated.

Entrepreneurs need to discover opportunities if they are to start new businesses. The fundamental questions of entrepreneurship research evolve around why, when and how some people are able to discover opportunities, while others cannot or do not? (Shane & Venkataraman, 2000). In today's competitive business environment also firms – and not only individuals - need to continually identify new opportunities beyond existing competencies if they are to survive and prosper. Prior knowledge of a particular field provides individuals the capacity to recognize certain opportunities (Venkataraman, 1997; Shane, 2000) In the same lines, firms tend to innovate in the areas where they already possess knowledge. A firm obtains information about entrepreneurial opportunities by mutual interaction with other market participants (Hayek, 1945). However, such information is dispersed unevenly among firms in the market. Owing to the variation in the information acquisition process, firms gain differential access to external information. Thus, they have different capabilities to see new markets and potential uses for existing (technological) knowledge and to understand their customers' needs and respond to them through new product development. It is for both of these purposes – i.e. market seeking and NPD - that firms generate market intelligence. However, frequently top management in small high technology firms is heavily biased towards technical disciplines such as science and engineering (Knight, 1986). Marketing and general management skills are often significant areas of weakness within small high tech firms, where entrepreneurs tend to over-emphasize the purely technological side of their business and neglect other key strategic issues (Knight, 1986; Oakey, 1991). This may lead to ignoring market intelligence generation, dissemination, and responsiveness to markets, which, in turn, may jeopardize the long term innovativeness and entrepreneurial spirit in such ventures.

Studies of entrepreneurship and technological innovation have much in common when explaining sources of information about entrepreneurial opportunities and new product ideas (Freeman, 1982; Scherer and Perlman, 1992). Opportunities are created in the process of technological innovation because of the change in existing resources, whether the change is disruptive or incremental (Utterback, 1994). If entrepreneurs discover information about these opportunities, they will capitalize upon the opportunities because the new combination of assets will result in profits. (Soh, 2003). Let us now look at market knowledge and its role more specifically in the context of technological innovations, i.e. new product development.

## **MARKET KNOWLEDGE AND NEW PRODUCT DEVELOPMENT (NPD)**

Two major reasons have been advanced in the new product development (NPD) literature to explain why listening to customers and partnering with them in NPD is beneficial (See e.g. Campbell and Cooper, 1999). Firstly, customers can provide major inputs which improve the quality of innovation. Second, especially in the settings of industrial markets and high technology products, close partnerships with customers during product development may provide access to resources that the manufacturer lacks in-house.

Recent research suggests that the degree to which a firm is involved in new product activity depends on the extent and nature of its market orientation (Athuene- Gima, 1996; Hurley & Hult, 1998; Frambach et al. 2003) and that market orientation and innovativeness are rather complementary than conflicting concepts (Slater and Narver, 1995; Becherer and Maurer, 1997). A central theme of the innovation- and NPD literature is that information gathering and analysis are critical to the successful development and execution of innovative strategies and new product development (Barringer and Bluedorn, 1999; Matsuno et al. 2002). In relation to market orientation of a firm – when understood as market intelligence generation, dissemination, and responsiveness to it in a firm (Kohli and Jaworski 1990) – innovativeness could be seen as “a consequence”. On the other hand, R&D and innovativeness have often been contrasted to marketing and market orientation in a firm (Christensen 1997; Hamel and Prahalad 1994). These contradicting views on the importance of market knowledge as a part of NPD may arise because of multiple reasons. It may be that the role and importance of customer input in NPD is dependent on the stage of the process (early vs. late stage NPD) as well as the nature of the product being developed (disruptive vs. continuous innovations).

## **CHALLENGES IN NEW VENTURES**

Harris (1999) divides the literature that has addressed barriers to developing market orientation<sup>1</sup> into two categories. Firstly, there are studies which focus on types of employees or employee behaviors. Secondly, other studies concentrate on systems and structures.

New technology ventures are often started by scientists or technologists that hold patent rights of inventions with commercial potential. E.g. Changanti & Sambharya (1987) have shown that the orientation of organizations is hugely dependent upon the commitment and abilities of top management. Messikomer (1987), Kelley (1990), and Gummesson (1991) have extended this argument to all levels of an organization; everyone in an organization is a potential barrier to the development of market orientation and, thus, to the dissemination of market intelligence within a firm. Since the principal barrier to market orientation development is the values, beliefs and assumptions of an organization (Messikomer 1987), technology oriented organizational culture in young technology firms is one potential challenge for integrating market knowledge into the whole organization, and especially to research and development of new products.

Focusing on systems and structures, Ruekert (1992) statistically analyzed the link between recruiting, training and reward processes, and market orientation of a firm, concluding that there was substantial empirical evidence to suggest direct associations. Jaworski and Kohli (1993) found that top management emphasis, reward systems, centralization, and connectedness each affect market intelligence generation and its dissemination as well as responsiveness to it in

organizations. Furthermore, interdepartmental conflict was found to affect intelligence dissemination.

Overall, the literature identifies numerous complex and interrelated challenges for the sourcing and integration of market information into all key functions of an organization. In the following, I report on a qualitative empirical study that has been conducted among young and small biotechnology ventures to find out about the challenges these firms face when trying to integrate market intelligence into organizational process, most notably R&D.

### **EMPIRICAL STUDY: METHODS**

The empirical study reported here is an integrated part of a study conducted to find out about market orientation in small biotechnology firms. The results reported here concentrate on the dissemination of market knowledge with a focus on marketing/business development and R&D interface, whereas the data collection was carried out to understand the larger concept of market orientation in the firms. Interview questions have been developed based on existing literature and pilot case studies of six biotechnology firms in early 2003. The unit of analysis in this research is the firm, and informants are company CEOs. Based on the pilot studies and existing literature, I concluded that there is a great variety of issues technology SMEs even in the same technological field face in the integration of market knowledge to their R&D activities. Consequently, instead of employing existing scales in the evaluation of these issues, I decided to take a more qualitative approach, use open ended questions, and let the respondents construct their answers themselves.

Empirical data was collected via face-to-face CEO interviews in small, young, and research intensive biotechnology firms in the US, Sweden, and Finland in 2003-2004. In each geographical area, biotechnology organizations' member listings have provided the basic directory, from which the populations of interest have been identified. The firms included in the study are independent, R&D based biotechnology firms with 250 employees or less, service firms excluded. Personal, one- to two-hour structured interviews were conducted in 85 such companies in Pennsylvania (n=13), Florida (n=19), Bay Area, CA (n=27), Finland (n=19), and Sweden (n=7). The first ten interviews also served as a pilot test for the questionnaire. Face-to-face interviews increase the validity of data collected. They are also probably the only way to reach the smallest firms, from which scarce secondary data is available. The mean size of these sample firms is 38 employees, and 81 per cent of firms employ 50 people or less. An average firm was six years old at the time of the interview. Most of the drug discovery and development firms do not have products on markets yet, whereas most of the medical devices firms typically do. This is due to the nature of product development in the two fields; pharmaceutical product development and testing is a process that requires typically 12 to 15 years. Table 1 below shows the key demographics of the firms included in the study.

---

**Table 1 here**

---

### **RESULTS: CHALLENGES IN INTEGRATING MARKET KNOWLEDGE TO R&D**

To understand the distribution of market knowledge within the study firms, I asked the managers to elaborate on “How would you describe the relations between people working in marketing/sales in your firm and other “departments”?” and “What kinds of challenges are there when you try to integrate the market intelligence into your R&D?”. The answers to these questions basically reflect three critical aspects of market knowledge on a firm level. In addition, some interviewees took an industry- or individual approach in their answers. Table 2 below summarizes the challenges in integrating market knowledge into R&D in the organizations studied.

---

**Table 2 here**

---

On the level of an organization, there are three kinds of challenges that prevent integration of market knowledge into R&D. Firstly, biotechnology companies are typically started by scientists or technology enthusiasts, which is reflected throughout the early years of operation of these firms. Some of the companies still operate in universities’ premises and are run by professors or ex-faculty. This naturally leads to excessive focus on technology and solving technological problems without devotion to business development and acquiring market knowledge. As suggested by Berry (1996), there is a continuum along which small high tech firms progress as they grow, from initial beginnings which are based on the internal technological competencies, towards an outward orientation focusing upon marketing issues.

Secondly, in most cases a small firm focusing on technology research and development does not have the resources to commercialize innovations to global end user markets. For distribution, commercialization and often also development of the innovation, these firms partner with larger companies. Often, the deals at this stage take the form of licensing deals. Many of the young, small biotechnology companies do not think they should worry about the marketability of the end product; instead of integrating end users views to product development, these small firms solely focus on meeting the milestones specified in the licensing deals and leave marketing and commercialization issues to the downstream licensing partners.

In addition, promising small, technology intensive firms grow rapidly over their early years of existence. Even if the growth in personnel is well planned out – which it often times is not – the growth brings along challenges for communication within the firm. Dissemination of market intelligence can initially be handled through informal meetings and “hall-talk”, but as the company grows there is more need for formalized channels of knowledge distribution.

Challenges do not only arise on the level of an organization, but also on the level of individuals interacting. In small biotechnology firms the “departmental” friction arises between individuals involved in R&D work – typically scientists – and those trying to make a business out of that science. At the very early stages of company development the two functions are actually carried out by the same people, focus being on science. Later on, when dedicated business development and marketing personnel is added to the team, the communication between them and the scientists presents challenges. Even though most interviewees described the relations between the two functions as “close” and “integrated”, they also identified challenges in communication and integration.

Finally, the field of biotechnology itself was mentioned by some interviewees as a challenging arena for combining market knowledge into R&D. The long product development time scales of medical products – especially pharmaceuticals - and scientific uncertainty of this development are reflected in the role that market knowledge gets in these firms. Overall, the less developed the product concept of the firm, the more difficult it is to talk about rigorous market research and knowledge. At an extreme, it may well be that the company does not initially know the potential its technologies have when applied into commercial purposes. When the goal of product development is not clear, it is naturally very difficult to gain knowledge of the markets for that product.

## **CONCLUSIONS AND IMPLICATIONS**

Small, young technology firms face a variety of barriers that hinder the integration of market knowledge into R&D. The typology developed in this paper reflects the various loci of these barriers. On the level of an organization, there are three kinds of challenges that prevent integration of market knowledge into R&D. Firstly, biotechnology companies are typically started by scientists or technology enthusiasts, who compose the top management team. These individuals do not typically emphasize the importance of market intelligence and its integration into research and development activities. Secondly, instead of taking products all the way to end markets, small and young biotechnology firms often aim at licensing their products to larger firms, who will take care of commercialization and distribution in the end. Thus, like suggested e.g. by Ottosson (2003), these firms do distinguish between customers and end-users and do not always see the need to integrate market knowledge that concerns end users into their R&D. Third, rapid growth of some technology firms over their early years of existence presents challenges; as the company grows, so does the need for formalized channels of knowledge distribution. Communication between scientists and business people in a firm often presents challenges because of the different mental models and goals of the two groups.

In addition to the organizational challenges, the field of biotechnology as such has a number of features that make it challenging for firms to integrate market knowledge into their R&D. Most importantly, the medical research and development process is a highly regulated one, and especially development that involves clinical trials is a long and expensive path. Because of the long time scales typical for biotechnology R&D, a reactive approach to, for example, competitors' actions is rather impossible. If a drug discovery company has proceeded to preclinical or clinical trials with an interesting new therapy, there are already numerous patents and probably years of scientific work behind the new therapy. Rapid, reactive responses by competitors are rather impossible.

So what is the take home message from this study to small firm managers? Initially, considering the science driven nature of biotechnology business, one is tempted to assume that market knowledge has a very limited role in small biotechnology firms. However, even though some researchers have even suggested that customer knowledge impedes innovation (Christensen 1997; Hamel and Prahalad 1994), growing body of literature on new product development suggests that innovation is achieved by combining technological knowledge with understanding of markets (Cooper 1988; Stevens et al. 1999). Even the early stages of pharmaceutical product

discovery and development are influenced by market considerations, typically channeled to firms through professional networks (Takayama & Watanabe, 2002). This study has identified bottlenecks that prevent the integration of market knowledge into research and development. Based on the study, technology venture managers that want to integrate market aspects into their companies R&D should be aware of the following traps: (1) excessive focus on science and technology instead of e.g. asking future end users of products for their opinions on product features; (2) excessive focus on meeting development milestones instead of visioning end products in the markets one day; (3) forgetting the development of internal communication within a firm especially in the times of rapid growth; (4) failing to understand the different goals and mental models of scientists vs. business people.

The research results reported in this paper is of interest for future researchers that want to study technology management, especially new product development, or entrepreneurial opportunity discovery. For those interested in NPD processes, the categories presented here can be further defined and empirically validated with a quantitative research design. For those interested in opportunity identification and innovativeness within existing small firms the results of this study raise following kinds of questions: If understanding markets as well as technology is critical for identifying opportunities, then how can firms identify opportunities if the two domains of knowledge within firms are separate? Do companies that are better in integrating market knowledge and technological knowledge also identify more entrepreneurial opportunities? And who are the entrepreneurs within existing small businesses – scientists, business people, or both?

THE LEADERSHIP STYLE OF WOMEN ENTREPRENEURS:  
AN ALTERNATIVE MODEL OF  
SUCCESSFUL MANAGEMENT PRACTICES

Mary Riebe

Center for Women Entrepreneurs and Entrepreneurship Education  
Metropolitan State University, Minneapolis, Minnesota

This study is based on the qualitative, comparative research, in which interviews were conducted with twenty-seven women business owners in three countries all of whom had founded and successfully grown their businesses into firms with annual sales exceeding half a million dollars. The findings of this research are also supported by three decades of working closely with women business owners in several consulting and educational settings.

This paper expands upon the earlier findings by more deeply examining the management philosophy and business practices that emerge from the experiences and successes of these successful, growth-oriented women entrepreneurs. The similarities among these women's leadership styles were constant across business size, industry, gender makeup, longevity, or the owner's age, educational level, previous work experience, or country. The only common factor shaping those responses is gender.

The findings suggest that these successful women more closely resemble those of other studied women entrepreneurs than the conventional "male" business model. The success of these women in motivating and retaining employees and in growing their companies demonstrates a highly successful alternative to the dominant model of running a company.

## **Introduction**

Internationally, women now account for 25-30% of all business owners and are starting businesses at twice the rate of men. This research contributes to our current knowledge regarding women entrepreneurs by examining growth-oriented women business owners, a largely overlooked category that has been ignored in the relatively small body of research on women entrepreneurs, which has focused almost exclusively on sole proprietors and owners of start-up and small companies. (Out of the thousands of research articles on entrepreneurship published between 1976-2000, a review by Greene, Hart, Gatewood, Brush, and Carter [2003] found only 173 specifically addressing women entrepreneurs, and few of those investigating management practices.)

This paper is based on an extensive research project in which I conducted in-depth interviews with twenty-seven women entrepreneurs in three countries--the United States, Ireland, and Finland--all of whom had founded and successfully grown their businesses into firms with annual sales exceeding half a million dollars. These countries were selected because they have

seen great increases in the number of women entrepreneurs, and the dollar amount because it represents the average revenues of male-owned businesses but of less than 10% of women-owned businesses. These interviews were guided by a set of 38 questions that explored the respondents' personal and professional backgrounds and a variety of issues germane to starting and growing a business. The findings of this research are also supported by three decades of working closely with women business owners in several consulting and educational settings, most currently as director of a university-based Center for Women Entrepreneurs.

In addition to offering new data regarding a significant but understudied population of entrepreneurs, this research offers new evidence relevant to the findings of both sides in the ongoing dispute among those scholars in the field who argue that women demonstrate a distinctive management style and those who claim that there are few actual empirical differences in the leadership practices of men and women business owners.

As I have reported earlier, the study found that in terms of character traits and attitudes, these successful women entrepreneurs more closely resemble their male counterparts than they do women owners of smaller businesses or women managers more generally (Riebe, 2001, 2003a, 2003b). These traits include similar propensities for risk-taking, achievement, autonomy, persistence, confidence, internal locus of control, and central life interests. In contrast to recent research describing women in business and the professions as ambivalent about ambition and success (Fels, 2004), the growth-oriented women in this study are very focused, resilient, determined, and self-confident.

When asked why they had started their businesses, their responses differed significantly from those of both men and women business owners queried in other studies. Unlike male entrepreneurs, none mentioned money or attainment of measurable financial goals, and only two indicated that they were motivated by family or personal issues—one by the death of a spouse and one because of a stress-induced illness—a finding quite different from earlier studies of the population of women entrepreneurs in general, among whom a desire to better balance work and home life has been found to be a major motivator. In contrast, they cited personal values, dissatisfaction, and situational pressures as driving their decision. These included their passion for the field, desire for independence, ethical differences, being bored or stuck in a corporate structure, discrimination against them as women, previous business closing, invitation to partner, and being unable to find anywhere they wanted to work.

In exploring their leadership philosophy and actual business practices, however, I discovered that these successful women more closely resemble those of other studied women entrepreneurs than the conventional "male" business model, and that they in fact attribute much of their success to those very practices. Their answers support the findings of scholars who have observed that women "think differently, manage differently, and define success differently" than their male peers (Center for Women's Business Research, 1994). (For fuller descriptions, see Weeks, 1994; Eagley & Karau, 2002; Eagley, Johannesen-Schmidt, & van Engen, 2003; Eagley & Johannesen-Schmidt, 2001; Fondas, 1997; Robinson & Lipma-Blumen, 2003; Entine & Nichols, 1997.) In Riebe (2003b), I have described the primary characteristics of this management approach as being (1) collaborative, (2) community-oriented, and (3) values-driven.

## Findings

This paper expands upon those earlier-reported findings by more deeply examining the management philosophy and business practices that emerge from the experiences and successes of these successful, growth-oriented women entrepreneurs. This particular set of subjects makes an especially good sample for examining this female management model, because as founders of their own companies, they have had full control over the organizational structure and work culture of their workplaces; this was not something they had inherited, but could shape from the beginning and maintain as their companies grew. Furthermore, the similarities among these women's leadership styles were constant across other possible explanations, such as business size, industry, gender makeup, longevity, or the owner's age, educational level, previous work experience, or country. In other words, these characteristics were true in companies with 50 employees or 500, in stereotypically male or female industries, in companies founded in the 1960s or the 1990s, in Helsinki or Boston. One could not guess the size, industry, age, or nationality of the women's company from their answers to my questions regarding their management philosophy and practices; the only common factor shaping those responses is gender.

Although most of the women did not have a formal education in business (although two had MBAs), all had experience working in other companies, most as managers, and thus they did not adopt their management style out of ignorance of the predominant model. In fact, they all reported making a very conscious choice when founding their companies to create a workplace environment that was different from the conventional business model with which they were familiar. As such, their philosophy constitutes both an explicit and implicit critique of that conventional model, one that their success should encourage us to take seriously.

In fact, to the extent that these women's past work experience influenced their vision of the workplace environment they wanted to create, it most often served as a negative example:

*In their jobs, I don't sweat the small stuff. At my previous company you would get called in if you were ten minutes late, which is the craziest thing I've ever heard of. They know what they need to do. (R1)*

*I know what it was like to work for someone else. If I had been treated the way I treat my staff, I would have died for my boss. I think that you can be very, very human. (R6)*

*I don't like the formality of business. I don't see that as existing here. My door is open all the time. Anybody can walk in or out, and likewise I can walk around and talk to everybody here. We don't have names on doors, and you don't have to go through my secretary to see me. I don't believe in that. I didn't like it when I worked for companies where it happened. (R10)*

In fact, many of the respondents noted that they had started their businesses in order to create a workplace in which they themselves could be authentic and productive. As one put it,

*It wasn't money. I think it really was to create a place for myself that I felt comfortable and exercise a lot of parts of myself. I could create the kind of environment that I really wanted to get up and go to work to everyday. (R14)*

Not surprisingly, some of their reported discomfort with the prevailing model was explicitly linked to their experience as women, but most was related to ethical issues and frustrations working within bureaucracies that, while not necessarily gender-specific, have been described in other studies as particularly discouraging to women in large organizations (Hewlett & Buck, 2005; Fels 2004). Thus their answers may serve to further explain or illuminate not only the behavior of female entrepreneurs, but also current research on why so many women managers are leaving their careers behind.

As noted earlier, the respondents also demonstrated a values-based approach to business that integrated their personal and professional commitments and values. These findings demonstrate that their workplaces were designed in large part to extend to employees the same values and desires that had led the subjects to begin their businesses in the first place. Among the conscious practices described by virtually all of the respondents was giving their employees a great deal of appreciation and recognition:

*There is one message I have to give to everybody. No matter how little you are, you are terribly important in any organization. And you must believe that you are, because that stimulates you to move a little farther. (R11)*

*Very strong feeling about respect. Respect the differences. I've been working very hard to make sure the unsung heroes are recognized. My employees gave me a bell. It's hanging in the warehouse, and people are supposed to ring the bell whenever anything good happens. I'm always complaining that it doesn't ring enough. The successes are the little things. The big things are easy. (R13)*

They also described offering their employees a good deal of flexibility, in terms of both time and task, and considerable trust in the form of independence and autonomy, all of which they had reported as chief among their motivations for starting their own businesses.

*One of the principles established early on was that employees should have a lot of flexibility. (R3)*

*I do expect them - because I'm not here very much - I expect them to run the show around here. Everybody does their own thing. If they have a problem, they talk with each other. We have fun. They have their own hours. If they are working on an area they don't like, I ask them what they would prefer to be doing. (R1)*

*I think we have a totally different work environment. We're here because we want to be. Willing to be accountable and take the risk. I delegate all kinds of responsibility. If somebody tells me they need a new computer, we get a new computer. I just write out the checks. (R2)*

*Absolutely. It's informal, the way we dress. We have flexible time. Particularly the creatives; they need to be managed differently. They need to have time away. I believe we've created a nice environment here, and I do it by modeling. The last two months, I leave for rehearsal every afternoon. I think that's a bigger impact than anything I could say. (R4)*

*If they want to have a role that is different, I try to give it to them. If they want to be free one day, I say okay, we'll arrange it. (R22)*

In their interviews, the subjects also described their management style and the working relationships within their businesses as equalitarian, collegial, and empowering. Many described their management philosophy as a team approach:

*I have a management team that reports to me who are top-notch, and we operate as a team. I don't make a lot of decisions myself anymore. (R14)*

*We work together as a team. It's very much based on team effort. I think that came from my involvement with Junior Chamber. Everyone worked as a team. There was never an issue about status or positions or matters, and I took it from there. (R9)*

*I think it's important to be part of a team. (R11)*

*We all work together. I've got a really good team. There's no sort of management system here. (R12)*

Many of the women used images of family and friendship to describe their management approach, as in the following comments:

*Oh, sure! It's not easy for people to come down at lunchtime, so we feed everyone. It's a homey feeling. We've got beds here. We work late. It's a family, I think, here. It's fun to be a part of it. (R15)*

*We have always tried to make the restaurant like we want – like a home for the workers. (R26)*

*Every day I think it is essential to go to each of them quietly, not publicly, to say "Hi, how are you? Any problems? How are you feeling?" You can kind of get into them that way. There might have been a horrible customer, they might have said the baby was up all night and have not gotten any sleep. But going and making them feel important, and they know it. I think it's important to be part of a team. (R11)*

*We try to keep it almost a family-type business. Everybody is as important as the other person. Nobody's more important. I don't want to tower over everybody: 'I'm the owner,*

*and I'm doing this.' That isn't the way I am. We can do this business together, and everybody's more important. (R15)*

*I don't know what my philosophy is. We do go on little trips. I take their kids to pantomime. We feed them. I think very strongly that you have to treat your staff well. (R12)*

An important element in the relationships they described as having with their workers is reciprocity. The women's heartfelt awareness of their interdependence was also reflected in a more participatory and democratic work and decision-making process.

*I really like to know them, their names, their values. I want them to know I care about them. We all help each other – I help them, they help me. (R23)*

*You only get back what you put in. (R12)*

*I try to be as fair as possible, and I try to manage them the same way I hope they are managing me. It is not easy, but a simple rule. (R24)*

*You have to have good people around you. You've got to have people to support you. You can say you're an owner of a business, but you didn't do it alone. I guess that's probably my advice - don't think you can do it for yourself, because you can't. (R15)*

Three of the respondents described this lack of hierarchy in almost identical terms:

*I have, yes. I consciously went out of my way, first and foremost, to get top-class staff and then give them their lead. I would try to create that environment where there's no boss. Okay, maybe you lead by example. I would never ask anybody to do something I wouldn't do myself. They know that. (R8)*

*My main one would be we're constantly on a friendly basis but not on a social basis. Most importantly, I don't ever ask my employees to do anything I wouldn't do myself and that goes down to office maintenance and upkeep. I think it's worked well. (R9)*

*Never ask them to do anything I wouldn't do myself. I see the people that have committed themselves to this company. They're involved with the company, and if this company can reward them for their loyalty and effort, they can share in the profits and share in what we have to offer, and I'm going to help them do that. (R10)*

While all the respondents were clearly successful leaders, a number explicitly rejected what they saw as the traditional role of boss, as in the following:

*We try to keep it almost a family-type business. Everybody is as important as the other person. Nobody's more important. I don't want to tower over everybody: 'I'm the owner,*

*and I'm doing this.' That isn't the way I am. We can do this business together, and everybody's more important. (R15)*

*I'm not the boss type at all. I mean I am not a very good manager. If I don't have a good friendship relation with my employees, it doesn't function. (R21)*

As the above excerpts from the interviews demonstrate, the subjects of this study spoke of their workers in personal terms, as family, friends, team members, partners, and equals, and described their management styles in terms familiar from earlier research claiming a distinctively female leadership style. Yet other scholars have challenged the validity of such self-reports, questioning whether they reflect actual practices in the workplace. Most recently, in a study of the management practices of men and women business owners subtitled "Gendered Rhetoric versus Business Behavior in Small Firms," Cliff, Langton, and Aldrich (2003) argue that although the women spoke of their management practices in more stereotypically feminine terms and men in more stereotypically male terms, their actual policies and practices were largely the same.

But before dismissing these women's descriptions as simply a matter of self-presentation, it should be noted that they all went on to describe a wide variety of specific practices through which they went out of their way to recognize and reward employees, to invite a more democratic and participatory work style, and to create a comfortable work environment that values workers as whole persons. This included deliberately trying to create family-friendly workplaces for their employees, even though, unlike many women owners of smaller businesses, they had not started their businesses in order to create more balance between their own family and work lives. They explicitly linked those practices to their own belief in the importance of families, their desire to contribute to the well-being of their communities, and their recognition of employees not only as workers, but as persons with families, needs, and obligations outside of the workplace. And while this study did not systematically observe the respondents' workplaces or interview their employees, I did interview each woman at her place of business and informally observed her interactions with her employees, and their practices seemed consonant with their descriptions.

Furthermore, I would argue that business owner's description of their management philosophies cannot be dismissed so simply a rhetoric, whatever form their actual implementation takes. Surely how one speaks about their leadership makes by itself a difference in how both entrepreneurs and employees view themselves, which in turn shapes their actions and interactions with one another. If a leader talks about their philosophy one way but acts another, this dissonance is going to create their ability to lead effectively. The success of the subjects' companies and their employees' satisfaction, loyalty, and retention would seem to speak at least as loudly about the reality and efficacy of the practices they describe.

### **Significance and Implications**

Yet in the end, the purpose of this paper is to analyze the management style described by these growth-oriented women entrepreneurs not as distinctively female but as demonstrably effective. That is, I am less interested in the degree to which these women entrepreneurs demonstrate a leadership style that is different from that favored by male entrepreneurs as I am in its

significance and implications for all entrepreneurs. Surely the success of these women in motivating and retaining employees and in growing their companies demonstrates a highly successful alternative to the dominant model of running a company, one applicable to male as well as female entrepreneurs and managers.

Thus this article is not arguing that the female management approach described here and elsewhere is necessarily superior, that women are necessarily better at it, or that its characteristics cannot be successfully adopted by men. The women I interviewed did not themselves describe their style as distinctively female, and were in fact adamant that they would give the same advice to both men and women wanting to start or grow a business. As Cliff, Langton, and Aldrich (2003) and other researchers have shown, many of these practices have already been appropriated by many male small business owners, a development, I would argue, that speaks less to gender than to their efficacy, the exigencies of small businesses, and the demands of dual-income families for more flexible and family-friendly accommodations. Furthermore, many elements of this approach have also been advocated by numerous widely-read management books intended for both sexes, including the books on managing for excellence, working in teams, and reengineering companies that Fonda (1997) analyzes and the more recent spate of books on such topics as character-based and reflective leadership.

One implication of the general applicability of this “feminized” approach to management (Fondas, 1997) is that it should be given more attention by entrepreneurship and management educators, who have been slower to incorporate it into their training of future business owners and managers than have executive development professionals and coaches. More specifically, the inclusion of more case studies involving female leaders, more women guest speakers, and more female mentors will expose students of both sexes to more female voices and approaches. Methods learned in the classroom are likely to be more effective if students of both sexes can connect them to their own worldviews and describe them in language with which they are comfortable.

Presenting female-friendly management approaches as legitimate may also help reduce the prejudice discussed by Eagley and Karau (2002), which makes it more difficult for women both to become leaders and to be successful in leadership roles. As the authors suggest, such prejudice might be lessened by changing the content of leader roles as such roles evolve toward more communal characteristics and fewer individualistic ones. As they and many other researchers have argued, adopting such a “feminized” approach becomes not only more acceptable but more urgent in today’s workplace and market. In their words, “Rapidly changing, globally competitive, high-tech environments may be inducing many organizations to adopt flatter, less centralized, more flexible structures and to develop participatory, delegatory, open-communication strategies conducive to rapid adaptation and responsiveness to customers” (25).

At the same time, that this approach is echoed in many of the practices of other women managers and business owners identified by earlier research studies does suggest that it may be more congenial to women, and this knowledge can be useful in designing women-specific programs that can address these “softer” and more “personal” issues directly and without apology or “translation.” After years of attending and hosting women-specific conferences workshops, I have found that discussions about business issues among women at such events tends to be talk

more about motivation and values than about skills and strategies, which male attendees sometimes find befuddling. Yet the high percentage of women business owners who seek out such opportunities testifies that many find it empowering to have place where they can discuss business issues in their own voice. More access to women talking about their own businesses and management principles in these terms may also attract more women to entrepreneurship.

In short, by developing a characteristic leadership style, these women entrepreneurs are not reinventing the wheel, but rather employing attributes to which they are socialized as women with traits they share with men to create high-growth businesses that can serve as a model for all entrepreneurs. As Entine and Nichols assert, “Neither men nor women have a lock on integrity, not on the ability to inspire a team, develop good personal relationships, and establish a flexible and accountable corporate structure—the diverse qualities all executives will need to make businesses thrive in the future” (1997, 4).

## **Abstract**

Women's productive activities, particularly in industry, empower them economically and enable them to contribute more to overall development of their country. Assisting women in achieving their leadership potential in business contributes to economic growth and to social and political development. However, in many societies such as Pakistan, women do not enjoy the same opportunities as men due to deeply-rooted discriminatory socio-cultural values and traditions, embedded particularly in the institutional support mechanisms.

The research conducted by the author shows that in Pakistan, women's full economic potential is not being tapped. Like most of the developing countries, women entrepreneurs in Pakistan also suffer from the lack of access to, including control over, capital, land, business premises, information and technology, training, production inputs, and assistance from governmental agencies. In addition, the main challenges they face are the limited spatial mobility, lack of encouragement from male family members, and improper networking mechanisms based on the widespread "religious belief" of its patriarchal society that men are inherently superior to women and that women are best suited to be homemakers.

The glowing role model of Prophet Muhammad's wife (Khadija, RA) and many other examples in the annals of Islamic history confirm that "women in business" are not frowned upon in Islam. The research also suggests that given the right moral and technical support, women entrepreneurs in Islamic society can also improve their success rate and their contribution to the economy. Therefore, awareness of women economic rights (confirmed by the religion) through media and inclusion in the education syllabus, in addition to better policy environment, revision of discriminatory legal rules and practices, increased access to finance and technology, provision of women-only business management training services, improved access to business development services (BDS), and more facilitation of national, and international networking for women entrepreneurs have been recommended to enhance women's entrepreneurship and integrate women into mainstream economic development.

## **INTRODUCTION**

Most of the emerging theories and prescriptions for success of women's entrepreneurship are derived from the growing body of knowledge comprising of the studies conducted in developed countries (Lerner et al, 1997). One of the main reasons is the scarcity of research conducted on the topic in developing countries (Allen and Truman, 1993). Whatever limited work that has been done on women entrepreneurs in the developing world, relates largely to the very poor and uneducated segments of women in the rural or the urban informal sectors. Most of this work has been conducted by the international development agencies, which have tended to focus on women's concerns from a 'macro-perspective' (Wees and Romijn, 1987). This is a critical omission from the understanding of women's entrepreneurship, because the social structures, work, family, and organized social life vary widely in developing countries (Allen and Truman, 1993; Aldrich, 1989).

As women's entrepreneurship development theories have emerged primarily from research in developed countries, it is important to examine the extent to which these apply in the context of developing countries such as Pakistan, where social and familial control over women's sexuality, their economic dependence on men, and restrictions on their mobility determine differential access of males and females to literacy and other supporting mechanisms.

The status of women in Pakistan is not homogenous because of the interconnection of gender with other forms of exclusion in the society. Religious prescriptions, cultural norms and actual practice, related to the women's status and role, vary widely and sometimes are highly contradictory. There is considerable diversity in the status of women across classes (the socio-economic status of a woman's family), geographical regions, ethnic origin and the rural/urban divide due to uneven socioeconomic development and the impact of tribal, feudal, and capitalist social formations on women's lives. However, no matter which class or region they belong to, women's situation vis-à-vis men, is one of systemic subordination, determined by the forces of patriarchy, greatly influencing their occupational role in all parts of the country by two factors, one being the cultural norm of 'Pardah'(veil)<sup>1</sup>, and the other being the notion of 'Izzat' (honor)<sup>2</sup>.

## **AIMS AND OBJECTIVES**

The aim of this study is to present a micro-level perspective on the gender-related challenges and opportunities of women entrepreneurs in the context of Pakistan. The intention is not only

---

<sup>1</sup> "Pardah, meaning curtain, is the word used to describe the system of secluding women and enforcing high standards of female modesty in South Asian societies, such as India and Pakistan. There are two instruments of Pardah, first is the system of female seclusion and sex-segregation, defining different spatial boundaries for the activities of men and women. Women's activities are limited mainly to the home, while men work outside. The second instrument of the Purdah is the veil, or the concealing cloak known as the 'burqa', worn by women whenever they venture outside the home. The veil or burqa is meant by to act as a portable means of seclusion" (Papanek, 1982).

<sup>2</sup> "Women are considered to be the repositories of a family's izzat or honour, and their chastity and good reputation is highly values and guarded"(Shaheed, 1990).

to provide evidence that women experience gender-neutral constraints, such as the lack of access to, including control over, capital, land, business premises, information and technology, training, production inputs, and assistance from governmental agencies but to move beyond, and to explore and illustrate the additional challenges that women experience as related to their gender, based on feudal, tribal, and geographical traditions in the name of religious values.

The study was intended to contribute to a greater understanding of women's entrepreneurship in a different and difficult cultural setting and to help policy makers and development agencies to understand the assistance needs and constraints that are specific to promote entrepreneurship potential of women in an Islamic society. Keeping in view of the aims and objectives, the research was guided by three main questions:

- Which gender-related factors influence the entrepreneurial capabilities of Pakistani women?
- What is the role of cultural norms of 'Pardah' and 'Izzat' (honor) in the performance of these business owners?
- What could be done to promote entrepreneurship potential of women in an Islamic society like Pakistan?

## **METHODOLOGY**

The instrument for collecting primary information was in-depth one to one semi-structured meetings with a sample of 256 women entrepreneurs in five major cities of Pakistan. The in-depth meeting was considered to be the most appropriate method for a couple of reasons. Firstly, the indigenous researcher was able to draw on his own understanding of how the respondents see and experience the world in supplementing and interpreting the data. Secondly, the in-depth interview enabled the researcher to capture the details needed for penetrating qualitative analysis without requiring contact over a prolonged period of time with the respondents. This was particularly important to enable participants to discuss what was important for them, their perceptions and feelings given the limited resources and time available to the researcher.

The study initially started with almost 100 names of entrepreneurs picked up through stratified sampling from the lists of Federation of Pakistan Chambers of Commerce and Industry, Export Promotion Bureau, Small and Medium Enterprise Development Authority, First Women's Bank, WEXNet-2001, and local directories/yellow pages. Many of the initial participants were generous in providing names of additional potential participants to be contacted. The sample was stratified according to the geographical location<sup>3</sup>; and sector of operation<sup>4</sup>. At least 25 women entrepreneurs were selected from each city and sector of operation.

---

<sup>3</sup> five major cities namely Karachi, Lahore, Rawalpindi/Islamabad, Quetta and Peshawar

<sup>4</sup> Manufacturing, retail trade, and services

The women entrepreneurs in this study are either owners of, or hold a controlling interest in an enterprise and manage it on a day-to-day basis. Out of 265 attempted contacts, only four declined, three were unavailable and in two cases it was not possible to arrange a meeting.

## **STRUCTURAL PROFILE**

Analysis of the data gathered through the research showed that majority of the women entrepreneurs (54%) owned/managed micro enterprises. Thirty six percent and 10% of the sample owned/managed small and medium enterprises respectively. These results are close (within +/-5%) to the structural profile of the women entrepreneurs described by a study conducted by ILO in 2001(Goheer, 2002). Most of the businesses (82%) are engaged in the traditional sectors of textiles and apparel, education, food, beauty, and health sector.

Deep rooted socio-cultural values of female segregation are evident in the industry profile. Majority of the female entrepreneurs (45.7%) are concentrated on the services sector and the local market, providing services mostly to the female customers. This is fairly typical of women's enterprises, in which the initial investment is relatively small and life experiences/hobbies are developed into businesses (Al-Riyami et al, 2003). Most of these services are in the sector where male-female interaction is either non-existent or minimum (in the case of education, beauty, and/or food sector). Manufacturing is mostly in the apparel and textiles sector, where most of the employees belong to the fairer sex, it consists of 34.4 % of the sample. Minimum numbers of female entrepreneurs (19.9%) are engaged in the retail sector due to increased chances of male-female interaction.

**TABLE 1: Industry Profile for Pakistani Women Entrepreneurs (n=256)**

| <b>Industry</b> | <b>Number</b> | <b>Percentage</b> |
|-----------------|---------------|-------------------|
| Services        | 117           | 45.7%             |
| Retail          | 51            | 19.9%             |
| Manufacturing   | 88            | 34.4%             |

## **PERSONAL PROFILE**

The literacy rate plays an important role to let Pakistani women aware of their rights (Shah, 1985). The same is evident from the result of this study that 82% of the sample are at least high school graduates, 52.7% earned their bachelor degree and 15.2% are post-graduate. One of the interesting facts is that their close relatives like father, mother, and husband are also well above the national literacy rate. Though, only 15.2% has formal education in management, 21.8% and 25.7% of them have previous managerial occupation and previous experience in industry.

One of the interesting finding is that almost 70% had their father and/or husband working as a business person at the time of start-up. Either those men supported their daughters and /or wives in the start- phase or at least encouraged them to take the plunge. Most of them (77%)

are married with children and became entrepreneurs when their children were grown. This is consistent with the strong family orientation prevalent in the Pakistani culture and the existence of acceptability of working women as long as she gives priority to family responsibilities.

**TABLE 2: Personal Profile for Pakistani Women Entrepreneurs (n = 256)**

| Variable  | Number | Percentage | Mean |
|---|--------|------------|------|
| Education level/high school                               | 212    | 82.8%      |      |
| Education level/university (Bachelor)                     | 135    | 52.7%      |      |
| Education level/university (Master)                       | 39     | 15.2%      |      |
| Area of university education: management, economics, etc. | 39     | 15.2%      |      |
| Previous entrepreneurial experience                       | 23     | 8.9%       |      |
| Previous managerial occupation                            | 56     | 21.8%      |      |
| Previous experience in industry                           | 66     | 25.7%      |      |
| Involvement in the start-up                               | 244    | 95.3%      |      |
| Membership in women's association                         | 77     | 30%        |      |
| Age of entrepreneur                                       |        |            | 39   |
| Marital status: currently married                         |        | 77%        |      |
| Number of children  |        |            | 3    |
| First child's age   |        |            | 16   |
| Father and/or husband in business                         | 179    | 69.9%      |      |

All interviewees were categorized as personal freedom seekers, personal security seekers or personal satisfaction seekers on the basis of reasons (such as family encouragement, ambition, independence, enjoyment, finance, economic necessity, challenge, corporate downsizing, job dissatisfaction, to utilize knowledge of skills, to make others happy, self recognition) for undertaking the business venture (Al-Riyami, 2002; Shabbir, 1996). Almost half of all the women interviewed (48%) started the business in order to maintain or improve their and their family's social and economic status. The need for the security of social and economic status was in many cases triggered by some personal mishap. Such as the death or retirement of whoever may have been the primary breadwinner in the family.

A number of women in this study (31.7%) took a decision to run their own business in order to prove to themselves and to others that they are a useful and productive member of the society. These were all women with little or no formal work experience, who were no longer content to be only a housewife. Most of them were relatively older women in their forties and/or early fifties. Only 20% opted to take a plunge in order to have the freedom to choose their own kind of work, hours, environment, and co-workers. These were mostly women who had experienced some kind of frustration in paid work and now wanted the freedom to gain control over their environment and type of work (Shabbir, 1996).

**TABLE 3: Category of Entrepreneurs based on Reasons for Starting up the Business (n = 256)**

| Category                      | Number | Percentage |
|-------------------------------|--------|------------|
| Personal freedom seekers      | 52     | 20.3       |
| Personal security seekers     | 123    | 48.0       |
| Personal satisfaction seekers | 81     | 31.7       |

Based on the findings of this study and information present in the literature (Goheer, 2002; Rajivan, 1997; Shabbir 1995; Shah, 1986), the common profile of the Pakistani woman entrepreneur can be summarized as: “a woman with a university/high school education, but an education unrelated to running her business; entering business in her thirties without a grooming for it, but with a strong motivation to do something significant; in their out of choice mostly for security reasons; restricts herself to one or two lines of business; preferring not to diversify; married with children; juggling between the enterprise on the one hand and home and children on the other; a supportive or at least a minimum objections family situation; coping in a much less supportive society which views her work as secondary business; without a serious motive”.

## CHALLENGES

An important question in entrepreneurship studies is whether women entrepreneurs face specific problems in setting up a business that are different from those faced by male entrepreneurs. Many researchers (Welter, 2004; McManus, 2001; Smallbone et al., 2000) indicate that women entrepreneurs experience a number of problems and issues that are greater than those facing small business in general. Based on the literature (Welter, 2004; Smallbone et al., 2000; Carter et al., 1998; Birley, 1989) challenges/issues were divided into gender-neutral and gender-related categories as listed in Table 4. The interviewees were asked to describe three biggest challenges faced in descending order in both the start-up and growth phases.

**TABLE 4: Challenges Faced by the Women Entrepreneurs**

| Gender-Neutral Challenges   | Gender-Related Challenges  |
|---|--|
| <ul style="list-style-type: none"> <li>• Access to Capital/Finance</li> <li>• Lack of Business Management Skills</li> <li>• Government Policy/Regulations</li> <li>• Registration</li> <li>• Utility Connections</li> <li>• Tax Harassment</li> <li>• Lack of Technical Skills</li> <li>• Purchase of Raw Material</li> <li>• Availability of Market</li> <li>• Access to Information Technology</li> </ul> | <ul style="list-style-type: none"> <li>• Spatial Mobility</li> <li>• Choice of Business</li> <li>• Support of Family</li> <li>• Networking and Trust-Building</li> <li>• Acceptance of Women’s Authority</li> <li>• Credibility (Employees, Customers, and Suppliers)</li> <li>• Fear of Failure</li> <li>• Time Distribution (Between Family and Business)</li> </ul> |

The biggest gender-neutral challenge was access to capital followed by lack of business management skills, and government regulations in the start-up phase. Again, access to finance was considered to be the most difficult challenge followed by the availability of the market, and lack of technical skills in the development (growth) phase. These results confirm the findings of previous studies (Nabeel, 2002; Roomi, 1999) that even in gender neutral problems women's immobility due to the notions of 'purdah' and 'Izzat' poses a big hindrance to all these problems in general and their access to capital in particular where female (nascent) entrepreneurs experience gender specific problems as well, i.e. mobilizing start-up capital, credit guarantees, investment capital, and possible discriminating attitude of bankers (Carter and Rosa, 1998).

**TABLE 5: Gender-Neutral Challenges\* Faced in the Start-up Phase**

| <b>Problems/Challenges</b>         | <b>1st challenge<br/>(% age)</b> | <b>2<sup>nd</sup> challenge<br/>(% age)</b> | <b>3<sup>rd</sup> challenge<br/>(% age)</b> |
|------------------------------------|----------------------------------|---|---|
| Access to Capital                  | 39                               | 27  | 21  |
| Lack of business management skills | 18                               | 21  | 25  |
| Government policies/regulations    | 8                                | 16  | 14  |

**TABLE 6: Gender-Neutral Challenges\* Faced in the Development (Growth) Phase**

| <b>Problems/Challenges</b> | <b>1st challenge<br/>(% age)</b> | <b>2<sup>nd</sup> challenge<br/>(% age)</b> | <b>3<sup>rd</sup> challenge<br/>(% age)</b> |
|----------------------------|----------------------------------|---|---|
| Access to Finance          | 27                               | 23  | 18  |
| Availability of Market     | 18                               | 21  | 26  |
| Lack of Technical skills   | 16                               | 24  | 21  |

\*Three most difficult challenges during the process in descending order

Most of the women are shy to approach banks because of the unavailability of collateral, their inability to develop viable business plan and above all social unacceptability of their interaction with the male bank professionals. They have to generate most of the finances through personal savings, family and friends. Because of their limited earning potential, it is quite impossible to have significant savings to start a business. Therefore, it is only possible for a female to start a business if her family has some extra cash as start up capital and she has a strong support from members of the family to do so.

Their restricted interaction with male members of the society limits the opportunities of acquiring business management and technical skills as there are very few institutions/organizations providing training only for women. They also face severe competition as far as the availability of market is concerned. Men are able to do much more than a woman and are able to attend or to appear in various places much more than a woman would do. In the Government departments man look at them as a "woman" (Al-Riyami, 2002). Women are encouraged to stay longer when they are there for official purposes, hence making delays in providing them with solutions regarding their problems. It creates frustration

for those women and worries for their families consequently discouraging them and other women to start their businesses.

## **GENDER-RELATED CHALLENGES**

The interviewees were asked to describe the gender-related challenges they face in start-up and growth phases as well. Not surprisingly, spatial mobility was considered to be the most challenging task for starting up a business. The restricted spatial has two dimensions, “One had to do with the actual physical limitation on the ability of women to move around because of the inadequacy of transportation facilities both private and public” (Shabbir, 1996). The second is the actual ability of women to move around freely. From the early childhood, they are not allowed to go out of their houses and mix with boys independently. They are protected and not encouraged to do things at their own. There’s a change in attitudes with the passage of time. Women are allowed to work in offices from 9 to 5 but it is very difficult for their families to allow them to move around freely to conduct their businesses.

**TABLE 7: Gender-Related Challenges\* Faced in the Establishment (Start-up) Phase**

| <b>Problems/Challenges</b> | <b>1st challenge<br/>(% age)</b> | <b>2<sup>nd</sup> challenge<br/>(% age)</b> | <b>3<sup>rd</sup> challenge<br/>(% age)</b> |
|----------------------------|----------------------------------|---|---|
| Spatial mobility           | 36                               | 32  | 31  |
| Choice of business         | 21                               | 12  | 4   |
| Support of family          | 19                               | 11  | 21  |

\*Three most difficult challenges during the process in descending order

Keeping in view of the problem of mobility, they have to restrict their businesses to areas, such as education, health, beauty, etc. where they provide services mostly to women customers or in the garments/textile sectors, where they have women employees to manufacture products for women customers. Though, one can find a few women working in the non-traditional areas but they can be counted on fingers and the most important factor for them being there is either involvement or support of their family to start and run that kind of business.

As their businesses grow, most of the women think that the hardest nut to crack is to deal with the labour. Most of the labour force is uneducated male, who are mostly rude and rough not ready to accept the authority of women. One has to be strong and stern to deal with them and their socio-cultural values prevents them to accept the same from a woman.

Another major gender-related challenge for women is to prove their credibility to the suppliers and customers. Especially, if they work in the non-traditional sectors, neither supplier nor customers take them seriously and consider that these women would not be able to achieve their target. They would not be able to pay in time to their suppliers and manufacture the goods or supply the products in time to their customers. They have to work hard to let their customers, suppliers and even employees aware of their credibility to run that business effectively and efficiently (Shabbir, 1995).

**TABLE 8: Gender-Related Challenges\* Faced in the Development (Growth) Phase**

| Problems/Challenges                           | 1st challenge (%age) | 2 <sup>nd</sup> challenge (%age) | 3 <sup>rd</sup> challenge (%age) |
|---|----------------------|----------------------------------|----------------------------------|
| Acceptance of women's authority               | 21                   | 20                               | 22                               |
| Networking and trust building                 | 17                   | 21                               | 15                               |
| Credibility (employees, customers, suppliers) | 19                   | 11                               | 10                               |

\*Three most difficult challenges during the process in descending order

Entrepreneurs require information, capital, skills, and labour to establish and develop their businesses. While they hold some of these resources themselves, they often complement their resources by accessing their contacts (Aldrich et al., 1989; Hansen, 1995). The contacts that lead to successful outcomes are their social capital and they are a key component of entrepreneurial networks (Burt, 1992). With respect to social capital in the form of networks, some research indicates gender-specific deficits in the networking contacts of female entrepreneurs even in western part of the world, drawing attention to the limited outreach and diversity of women entrepreneurs' networks (Cooper, Folta, & Woo, 1995; Aldrich et al., 1989). The same problem is evident in Pakistani women entrepreneurs as well with it severity because of the fact that it is very difficult for women to commute and get together at a place away from their homes. Most of the women feel that there is a lack of networks to exchange information, discuss issues, and seek advice on common topics, which is vital for the success of businesses.

## **PRACTICAL RECOMMENDATIONS**

The research suggests that most of the problems/challenges faced by Pakistani women entrepreneurs are a result of the inferior status of women in society, their underestimation as economic agents as well as the gender bias embedded in the regional, tribal, and/or feudal culture in the name of Islam. The main reasons of the challenges they face are the notions of 'purdah' and 'Izzat', which place severe restrictions on their mobility and they are not allowed to go out and work with men, which might cast doubts on their good reputation and reduce their marriage prospects (Shabbir, 1996; Shah, 1986; Hibri, 1982).

The most important point to mention is that there is nothing in the Qur'an<sup>5</sup> or in the hadith<sup>6</sup> which prevents women from working outside the home. In fact the Qur'an extols the leadership of Bilqis, the Queen of Sheba for her capacity to fulfill the requirements of the office, for her political skills, the purity of her faith and her independent judgement (*Al Naml*, 27:23-44). If a woman is qualified and the one best suited to fulfill a task, there is no Qur'anic injunction that prohibits her from any undertaking because of her sex. The hadith literature is replete with women leaders, jurists and scholars, and women who participated fully in public life. There is another hadith which states that 9/10 of our sustenance comes from business. For

<sup>5</sup> The Holy Book for Muslims

<sup>6</sup> Sayings of Prophet Muhammad

those who are able and are competent, Islamic society should encourage them to become entrepreneurs or get involved with other types of business activities (Hibri, 1982).

It is a fallacy to say women do not need work and that men have the primary responsibility to provide for their families. The glowing role model of Prophet Muhammad's wife (Khadija, RA)<sup>7</sup> and many other examples in the annals of Islamic history confirm that "women in business" are not frowned upon in Islam (Haddad, 1998). They are allowed to generate moneymaking activities that can help improve the economic state of the family, and the community. Therefore, Pakistani society's inclination to deny women the right to work on the basis of religion is an unrealistic proposition. It is just like that in large part of the society women have been denied the right to get education even though Islam has made it compulsory for men and women to pursue knowledge. Islam has given women the right to own property, to own business, to keep her 'maiden name', to choose her spouse, to divorce, to hold political office, and equality in honour and respect (Ahmad, 1992). The right to work is also an inalienable right of women, which is never objected by Islam. If this right is denied, it will, as a consequence, deprive women choice in many areas and affect other inter related rights such as the right to get education, the right to mobility, the right to decision making, and to political participation (Jalal, 1991). Therefore the situation demands following steps to be taken to improve women entrepreneurship opportunities:

- The first and foremost priority should be the 'True Islamisation' of thought regarding the status of women in the society. There's a need of change in syllabus at the school level to let society know the importance of inclusion of the womenfolk in economic activities. It can help changing the stereotype images of women in the society and encourage family support and help, which usually has a positive influence on women, both in venturing into and in making progress in business.
- Inadequate public transport plays a major role in immobility of women in Pakistan. Due to religious and cultural reasons-mainly purdah-the public transport facilities such as buses and vans have separate seating arrangements for men and women. These public buses and vans only have the first two or three rows of seats available for women. All the remaining seats are for men. This seating arrangement may have been adequate thirty years ago, when few women came out of their houses and fewer still went to work. But things have certainly changed dramatically since then. More and more women are now coming out to work, and the demand for transportation facilities by women has increased dramatically, but still only two or three rows are available on buses and vans for women (Shabbir, 1995). People don't like their women to go out as there are not enough seats for women to commute and being a developing country not all have the financial muscle to own a private conveyance. There is a dire need to change the whole system or at least provision of more seats for women in public transport. Government should play a vital role in providing these services as more women would be able to embark upon the business initiative if the problem of mobility is solved.

---

<sup>7</sup> Khadija (RA) the first wife of the Prophet Muhammad, was one of the most successful traders of Makkah.

- Media can play an important role by portraying the appropriate picture of the ‘muslim woman’ (who has the right to acquire knowledge through education, right to own property and to have her own business) by showing the positive role models of successful women entrepreneurs. It will not only influence other women in their decisions and choice of careers but will also create a suitable environment for their family members to allow them to venture into their own businesses.
- Women generally have less access to external funding than men; hence women’s businesses tend to be concentrated in the service sectors, which usually require small initial capital outlay and less technical knowledge. Government has taken a few steps in improving their access to finance such as incorporating First Women Bank (a commercial bank for the women by the women), and establishing Pakistan Poverty Alleviation Fund (for the provision of micro-credits to women). However, there’s a need of more flexible banking policies especially for women, keeping in view of the unavailability of collateral and their inability to develop viable business plans.
- Research suggests women-only training can play an important role in developing the next generation of leaders, and in the enhancement of their careers (Vinnicombe and Singh, 2003). Non/limited-availability of women-only training opportunities has been expressed by the interviewees as a major cause of their lack of business management skills in the start-up and growth phase of their businesses. Women-only entrepreneurship training programmes in addition to, and not as a substitute for, other entrepreneurship courses and support mechanisms such as mentoring and coaching, can provide them with an opportunity to learn primary, hands-on techniques of running a business in socially acceptable and culturally viable environment.
- For local markets, there may be limited support to forecast market and financial trends because of lack of data. Business support institutions such as Export Promotion Bureau, First Women Bank, and Small and Medium Enterprise Development Authority should develop a mechanism of hand-holding of selected women entrepreneurs to tap international markets.
- Marketing gap can also be fulfilled with good networking among women entrepreneurs. To ensure that their businesses progress smoothly, established women entrepreneurs should establish networks to help other women entrepreneurs. Existing networking organizations such as chambers of commerce and Women’s entrepreneurs associations has limited membership and confined regional outreach. There’s a need to assist the existing forums to play an important role by providing women entrepreneurs business development services (BDS), especially for new and potential women entrepreneurs who are in need of these services.

# ENTREPRENEURIAL COGNITION AND THE DECISION TO EXPLOIT A VENTURE OPPORTUNITY

Ingrid le Roux<sup>1</sup>, *Chair in Entrepreneurship, University of Pretoria, Pretoria, South Africa*

Marius Pretorius, *Chair in Entrepreneurship, University of Pretoria*

Sollie Millard *Dept. of Statistics, University of Pretoria*

## Abstract

This paper reports on decision-making cognitions just before and during the start-up decision within the entrepreneurial process. It uses empirical results based on responses collected through questionnaires from 300 entrepreneurship, business, non-business students and entrepreneurs as respondents. The importance of entrepreneurial cognitions is reported and the possible implications of these correlations are explored.

Using a case design required respondents to read a case and decide whether they would start the venture or not. First viability thought about the venture happened as early as reading 12% into the case with 81% of the respondents having their first thought about viability before reading 36% of the case. As all the financial information was attached at the end, viability was judged to large extent without reading financial information. This confirms that respondents appear to have used heuristics (shortcuts) and biases to make their decision.

Correlation and inter-correlation strengths and directions between business risk perception, misconceptions, self-efficacy and illusion of control bias with the start-up decision and viability thoughts were established. Highly significant differences between those who supported the start-up and those who did not support start-up were observed for business risk perception and misconceptions, significant difference for illusion of control bias but none for self-efficacy.

Discriminant analysis and logistical regression analysis were performed to predict the start-up and not start respondents based on the business risk perceptions and misconceptions. It was possible to predict the not start category accurately (81.3%) with the discriminant analysis and the start-up category accurately (96.48%) with the logistical regression analysis based on the misconceptions and business risk perception.

The paper concludes the importance of cognitions in entrepreneurial thinking and the tendency to make judgments without complete information. This may lead to decisions that can contribute to failure or may be reason why entrepreneurs are successful.

**Keywords:** Entrepreneurial cognition, risk perception, start-up decision, misconceptions

## 1 INTRODUCTION AND BACKGROUND TO COGNITION

The field of entrepreneurship seeks to understand how opportunities are discovered, created and exploited (Markman, Balkin and Baron 2002:149). The cognitive perspective, on the other hand, emphasises the fact that mental processes influence everything we think, say or do during this start-up process. These mental processes include the cognitive mechanisms through which we acquire, store, transform and use information (Baron 2004:221). The cognitive perspective provides us with some useful lenses with which to explore entrepreneur related phenomena and to address some meaningful issues that to this point we have been largely ineffective in probing (Mitchell, Busenitz, Lant, Mcdougall, Morse and Smith 2002:93).

Shepherd and Kreuger (2002:177) confirm that social cognition research offers considerable direction to understanding entrepreneurial thinking. Recent research has demonstrated the impact that cognitive and social processes have on entrepreneurial behaviour (Gatewood, Shaver, Powers and Gartner 2004:187). Although cognitive research has been going on for over a century, research in the entrepreneurial domain has prospered over last two decades (Baron, 1998:278) and led to the identification of several areas where it is specifically relevant for entrepreneurship namely:

- Our capacity to process new information about the world around us is severely limited and can be readily exceeded (Baron, 1998:278).
- We use sense making processes to scan through information (Forbes, 1999:415).
- As human beings we seek to minimise cognitive effort in coping with the information overload. As a result, we often use various heuristics (short cuts) in our thinking, techniques that reduce mental effort (Baron, 1998:278).
- Because of our limited information processing capacity, our tendency to minimise mental effort and several other factors (e.g. The powerful impact of emotions on thought), we are often less than totally rational in our thinking (Baron, 1998:278).
- Various aspects of human cognition are subject to a wide range of biases and errors (Baron, 1998:278).
- The environment wherein entrepreneurs operate is complex and demands quick decisions while the concepts of cognitive psychology are increasingly being found to be useful tools to help probe entrepreneurial related phenomena.
- The underestimated role of intuitive (sensing) rather than rational (thinking) in information on decision-making (Hayes and Allison 1994:59)
- Insights from the rich, broad social cognition literature give us several new insights about how to develop an entrepreneurship-friendly “cognitive infrastructure” at both self and collective efficacy level (Shepherd and Kreuger (2002:177).
- When receiving equivocal information, individuals are likely to perceive that which they are predisposed to see (Palich and Bagby 1995:428). Such predispositions and preferences for information when thinking has been categorised by Herrmann (1996) into four categories namely factual, procedural, affective and experimental information.
- The use of shortcuts, or heuristics, is sometimes efficient in that they facilitate judgements without tremendous information processing costs (Gowda 1999:60) as typically faced by the entrepreneur.
- The human judgement theory and decision-making are characterised by biases, errors and the use of heuristics (Watson, Rodgers and Dudek 1998:495).

The cognitive perspective should be viewed as complementary to, rather than incompatible with, other points of view in entrepreneurship such as personality and characteristic traits. The cognitive perspective may provide additional insights into the complex process of entrepreneurship (Baron 2004:237).

While the importance of entrepreneurial cognitions is acknowledged, the question arises if and how cognitive processes can be influenced by education. This paper attempts to better understand the thinking of respondents when faced with the decision of starting or not starting a business venture based on the perceived opportunity. Manimala (1992:478) proposes that the cognitive approach may be of more use to training and education of entrepreneurship than both traits and characteristics for which the findings proved mostly inconclusive (McClelland 1986 as quoted by Manimala 1992:479). Unfortunately it is difficult to compare thinking patterns between entrepreneurs, as there are too many complexities and different factors from the comparative environments, industry and business specifics that make it impossible to meaningfully compare them. For this reason an experimental design is pursued in this research (See research methodology).

## 2 THE NEW VENTURE CREATION PROCESS

Shook, Priem and McGee (2003:381) proposes an organising model that includes the following four stages (also shown in Figure 2) of venture creation namely: Entrepreneurial intent to start-up, searching for and discovering an opportunity, taking the decision to exploit the opportunity by new venture creation and then engaging in the exploitation activities.

Within each of these stages the role of the enterprising individual has been studied. They suggest that there is room for research to develop the understanding of cognitive processes during the different stages but simultaneously point out that the number of variables that determine each specific venture creation situation are so many that meaningful comparison of entrepreneurs is virtually impossible due to the complexities associated with each of the combinations of variables.

This article focuses on the thinking of respondents before and when they take the decision to start or not to start a venture. At the time respondents make the decision, the opportunity has been found (through whatever process might have been relevant at the time), and evaluation of the opportunity is foremost. At this point the entrepreneur is normally overloaded with data and information of different kinds (rational, procedural, innovative and intuitively felt information). Figure 2 shows the focus of this study relative to the entrepreneurial process as well as the specific constructs investigated and reported.

## 3 THE ROLE OF COGNITION ON ENTREPRENEURIAL DECISION-MAKING

### 3.1 *Cognition and the entrepreneurial decision*

Cognition (mental models) and cognitive psychology concern themselves with the study of individual perceptions, memory and thinking (Mitchell et al 2002:96). It involves all processes by which sensory input is transformed, reduced, elaborated, stored, recovered and used. Social cognition theory considers that individuals exist within a total situation or configuration of forces described by two pairs of factors: one being cognition and motivation, and the other being the person in the situation.

Cognition has to do with mental processing (thoughts) that individuals use to interact with their environments and helps to distinguish between entrepreneurs and non-entrepreneurs. Entrepreneurial cognitions have to do with the knowledge structures that people use to make assessments, judgements or decisions involving opportunity evaluation, venture creation, and growth (Mitchell et al 2002:97). In other words, research in entrepreneurial cognitions is about understanding how entrepreneurs use simplifying mental models to piece together previously unconnected information that helps them to identify and invent new products or services, and to assemble the necessary resources to start and grow businesses as well as pursuing opportunities or not.

Figure 1 shows a model for information processing as suggested by Miller (1987) as quoted by Hayes and Allison (1994). The role of perception (pattern recognition and attention) and thought (inductive reasoning as seen in classification, analytical reasoning and judgement) can influence the final response of the individual (Mitchell, Smith, Morse, Seawright, Perero and McKenzie 2002:13).

---

Insert Figure 1 near here

---

Baron (1998:297) suggests that entrepreneurs are more exposed to factors such as information overload, high uncertainty, high novelty, strong emotions, time pressure and fatigue than non-entrepreneurs. This leads them to increasingly being susceptible to the use of heuristics and biases such as counterfactual thinking, regret affect infusion, self-serving bias, planning fallacy, illusion of control, overconfidence and belief in the law of small numbers and self-justification. Based on Figure 1 the role of using the case study and leading to the start-up decision for the research was born. Finding the role of risk perception, self-efficacy, misconceptions and illusion of control bias is explored further.

### 3.2 *Business risk perception and decision-making*

Risk perception refers to the subjective judgement of the amount of risk inherent in a situation and has been found to differ between entrepreneurs and non-entrepreneurs (Keh et al 2002:19). Reduced perception of risk therefore contributes to the reason why some people but not others become entrepreneurs (Baron 2004:237).

Palich and Bagby (1995:426) reports that entrepreneurs did not vary significantly in their responses to a risk propensity scale, meaning that they did not perceive themselves as being any more predisposed to taking risks than non-entrepreneurs. However, multivariate tests revealed that entrepreneurs categorised equivocal business scenarios significantly more positively than did other subjects, and univariate tests demonstrated that these perceptual differences were consistent and significant (i.e. entrepreneurs perceived more strengths versus weaknesses, opportunities versus threats, and potential for performance improvement versus deterioration).

Risk perception is also influenced by cognitive biases. Simon, Houghton and Aquino (1999:113) report that before the decision to exploit the venture creation opportunity is taken, risk perceptions may differ because certain types of cognitive biases lead individuals to perceive less or more risk. These cognitive biases are common types of mental shortcuts used to make judgements. While judgment is at the heart of the decision making process, it involves several cognitive processes.

Based upon the tenets of cognitive theory, entrepreneurs may simply categorise and subsequently frame the same stimuli differently from non-entrepreneurs. That is, what has been widely recognised as a propensity for risk on the part of the entrepreneur may instead be an artefact of alternative framing based on misconceptions. Entrepreneurs may not necessarily prefer to engage in less risky behaviour; instead, their behaviour may be the result of different misperceptions about a given situation, thereby choosing to start the venture as a result of these misconceptions.

### 3.3 *Misconceptions and decision-making*

In the whole problem of a misfit between the entrepreneurs' cognitive make-up and the varying demands of the new venture over time, the central element is the individual entrepreneur. Both Busenitz & Barney (1997) and Baron (1998) found that entrepreneurs and managers use different biases and heuristics when faced with complex situations. These findings may explain the fact that entrepreneurs tend to operate in more uncertain and complex environments than do other individuals (Brigham & De Castro 2003: 42).

Very often entrepreneurs ignore the likelihood that the new venture will encounter substantial competition. According to Lieberman & Montgomery (1985:5) and Simon & Houghton (2002:10) underestimating competitive response can be defined as the extent to which a company will gain an advantage by pioneering its contingent upon the actions of its competitors.

Entrepreneurs are often overly optimistic in their perception of market acceptability. They believe that the output from this new venture will achieve its planned acceptance in the market place. According to Simon and Houghton (2002:11) the believe in small numbers bias may explain why entrepreneurs overestimate demand because individuals who utilise limited amounts of information may unintentionally select positive and not negative information, which could lead to overly optimistic forecasts of what their sales and in turn what the demand for their product could be.

Simon and Houghton (2002) argue that many pioneer entrepreneur's fail because they lack complementary assets. Complementary assets can include the following: sales and distribution costs, storage and stock holding and finance for slow payment. Misjudging these is a typical cause of failure in start-up ventures.

Misjudging the need for complementary assets can contribute to this misperception by creating an overly simplistic view of a very complex situation. These miscalculations may be more likely to occur in pioneering decisions, because the entrepreneur in pioneering decision context do not have other industry models to compare with and therefore have fewer cues regarding the potential problems of lacking complementary assets (Simon and Houghton, 2002:12).

### 3.4 *Self-efficacy (believe in own ability to effectively accomplish) and decision-making*

Beliefs in personal efficacy constitute the key factor to human agency. If people believe they have no power to produce results, they will not attempt to make things happen. In social cognitive theory, a sense of personal efficacy is represented as proportional beliefs that are embedded in a network of functional correlations with other factors that operate together in the management of different realities (Bandura 1997:3).

Efficacious people are quick to take advantage of opportunity structures and figure out ways to circumvent institutional constraints or change them by collective action. Conversely, inefficacious people are less apt to exploit the enabling opportunities provided by the social system and are easily discouraged by institutional impediments (Bandura 1997:6).

Shepherd and Kreuger, (2002:171) quote Bandura (1991) and Waung (1995) to describe people with high self-efficacy as those who have a high level belief in their capacity to perform. Self-efficacy refers to the conviction that one can successfully execute the behaviour required or the amounts of faith entrepreneurs have in their own ability to succeed (La Pira and Gillin 2004: 272). Thus it reflects the perception of a personal capability to do a particular job or set of tasks. Self efficacy impacts our perceived control, how much stress, self blame and depression we experience while we cope with taxing circumstances, and the level of accomplishments we realise (Markman et al 2002:152). High self-efficacy leads to increased initiative and persistence and thus improved performance. Indeed people with high self-efficacy think differently and behave differently than people with low self-efficacy.

Entrepreneurship scholars have found that self-efficacy is positively associated with the creation of a new independent organisation (Shepherd and Kreuger 2002:171). It may be argued that the impact of self-efficacy is more related to the intent and opportunity identification phases of the entrepreneurial process but this study attempts to determine the correlation with the decision to exploit the opportunity as well as its correlation to the risk perception. Based on the above, people with higher levels of self-efficacy, might perceive opportunities differently to those with lower levels of self-efficacy.

Entrepreneurial self-efficacy is widely regarded as a moderator of the relationship between individual perceptions and the development of entrepreneurial intent. Demographic characteristics appear to influence perceptions of feasibility, desirability and social support, and entrepreneurial self-efficacy within a complex set of cognitive mechanisms (Shook et al 2003:385). In short, perceived self-efficacy is central to most human functioning, and since actions are based more on what people believe than on what is objectively true, thoughts are a potent precursor to ones level of motivation, affective states and actions (Markman et al 2002:152). They state that self-efficacy impacts on entrepreneurial pursuits.

La Pira and Gillin (2004:272) further suggest that neither education nor training seem to contribute to the level of confidence or faith associated with self-efficacy, thus questioning the direct influence of education and training on this construct. Self-efficacy is rather causal to behaviour than vice versa. Efficacy beliefs therefore operate as a key factor in a generative system of human competence. Hence, different people with similar skills, or the same person under different circumstances, may perform poorly, adequately, or extra ordinarily, depending on fluctuations in their beliefs or personal efficacy (Bandura 1997:37).

### 3.5 *Illusion of control bias and decision making*

Bias is common in mental processing tasks such as diverse as target recognition, heuristic estimation and social judgement. Cognitive biases reflect the silent operation of neural modules that enhance adaptive behaviour and works automatically. Per definition, bias refers to a systematic preference, which primes either the selection of targets or recruitment of operational modes that results in weighted options in cognitive routines. Such weightings usually produces efficient performance but can also lead to false observations or deductions (Tobena, Marks and Dar 1999:1047).

Illusion of control is one such bias in which an individual overemphasises the extent to which his or her skills can increase performance in situations where chance plays a large part and skill is not necessarily the deciding factor. For example, people fail to respond differentially to controllable and uncontrollable events (Langer 1975 reported by Keh et al 2002:131). They report two reasons for this illusion of control namely that people are motivated to control their environment and the feeling of competence will result from being able to control the uncontrollable and secondly that skill and chance factors are closely associated and it is often hard to discriminate between skill and chance factors.

Therefore, individuals exhibiting an illusion of control will underestimate risk because they believe their skills can prevent negative occurrences (Keh et al 2002:131).

### 3.6 *Thinking preferences*

Thinking preferences as based on the Herrmann Brain Dominance Instrument (HBDI) also influence all cognitive activities including conceptualisation in equivocal and complex situations (Maree and De Boer 2003:453). The tendency to be led by one's preference for certain types of information and avoidance for others when perceiving the world around us, therefore supports why individuals frame the same situation differently. When faced with a problem situation, an individual will mostly follow the preference order for information starting with the highest preference first, then second and third most preferred ending with the least preferred type. These preferences are also related to how people frame their perceived environments. The natural preferences of people may also change towards another category when under pressure (Herrmann 1996).

For the entrepreneurship researcher, the question that arises is whether people could learn to change the way they perceive situations to enhance future decisions.

## 4 PROBLEM STATEMENT, HYPOTHESES AND RESEARCH METHODOLOGY

Several authors identify the use of cognitions by entrepreneurs to be different to that of non-entrepreneurs. Prospective entrepreneurs are faced with the same complex situations and lack of experience and previous exposure may force them to use certain thinking biases and heuristics.

### 4.1 *Problem statement*

Cognitions have to do with several complex interrelated systems that may vary over subjects and environments. Although there are several theories about these relationships, few have been tested empirically for the start-up decision. This research is concerned with establishing the strength and direction of these correlations and how they may impact the start-up decision. A better understanding of the difference between entrepreneurially oriented and other groups will help to establish the extent, if any, of such relationships. Secondly the question is asked what the implications of these cognitions and correlation can be on entrepreneurial education and learning. Is it necessary for educators to consider it? To study these potential correlations, the following hypotheses were set to guide the thinking of this article.

### 4.2 *Hypotheses*

To lead the thinking of the research in this process setting, five main hypotheses were set as shown in Figure 2. All the null hypotheses proposed that there is no relationship with the

decision to start while the alternative hypotheses were all proposing a correlation between the factors with the decision to start.

Ho1: Business risk perception has no correlation to the start-up decision (Ha1: there is a correlation)

Ho2: Misconceptions have no correlation to the start-up decision (Ha1: there is a correlation)

Ho3: Illusion of control bias has no correlation to the start-up decision (Ha1: there is a correlation)

Ho4: Self-efficacy has no correlation to the start-up decision (Ha1: there is a correlation)

Ho5: Thinking preferences have no correlation to the start-up decision (Ha1: there is a correlation)

Insert Figure 2 near here

#### 4.3 *Design and process*

Similar to Simon et al, (1999:120) a case was designed that described a revolutionary new concept namely animal fodder manufactured from cut lawn grass. In addition to describing the venture's proposed product and market, processes as well as expected performance and resource requirements. The case provides both encouraging and discouraging information, information covering the four thinking preference types regarding the venture's potential. The case length (8 pages including financials or 240 lines plus financial statement), its ambiguity and complexity required respondents to apply all possible information processes to determine whether they would start the venture or not.

Using the case method eliminated many of the environmental factors that complicate comparison of the individual's thinking and behaviour between situations associated with different entrepreneurs, macro and market environments, industries, competitive levels, venture characteristics etc. Using the case ensured all subjects analysed the same venture and complexities. Korunka, Frank, Lueger and Mugler (2003:26) suggest that the difference in environmental conditions should always be considered in relation to entrepreneurial character, resources and organising activities as it plays a crucial role. This approach allows for "control" of an external variable.

To ensure elimination of potential information framing effects such as attribute framing, goal framing and risky choice framing as described by Levin, Gaeth and Schreiber (2002:412), care was taken with the presentation of the case. Positive and negative information, advantages and disadvantages as well as positive and negative consequences were balanced. During the creation of the case, the distribution of information type was balanced to give equal factual, procedural, affective and experimental information according to Herrmann's (1996) classification. While all four types of information was readily available, the factual information was somewhat more and the affective information somewhat below the average due to the inclusion of financial statements mainly.

Respondents were requested to avail themselves for an hour to participate in the research. Of this, the reading of the case took between 20 – 30 minutes where after the respondents were urged to start with the questionnaire.

#### 4.4 *Instrument*

A questionnaire was designed covering the different aspects related to the problem. It covered questions on: information used for decision-making, information requirements to make an improved decision, self-efficacy, risk perception (Keh, Foo and Lim 2002:141), illusion of control, misconceptions (Simon and Houghton 2002:114) associated with start-up mistakes and how individuals tend to frame their environments.

#### 4.5 *Subjects*

Two hundred and fifty students from a major university in South Africa and 50 entrepreneurs were asked to participate. Respondents were drawn from different groups namely: B Com students majoring in entrepreneurship (representing those who already made a choice for entrepreneurship and starting a business), B Com students not majoring in entrepreneurship (making a choice for a career in the business domain), students from humanity majors (representing a choice “against” entrepreneurship and business), post graduate (M Phil and PhD Entrepreneurship candidates representing a late choice for involvement in the entrepreneurial domain) and entrepreneurs (the real thing) that were willing to participate.

The sample depended on respondents who had previously been assessed with the HBDI™ instrument (Herrmann Brain Dominance Instrument) because part of the overall study investigated thinking preferences as a potential heuristic used in the decision to exploit a business opportunity or not (convenience sampling was used). The cost of the HBDI assessment (R513 = approximately \$90 per assessment) limited the sample size.

#### 4.6 *Statistical Procedures*

Each of the constructs described previously were evaluated by respondents with statements (several items per construct) on a seven point Likert-scale as reported to be used in previous studies namely:

- *Decision to start a venture* was determined by one statement where respondents were asked to state their agreement with starting versus not starting on a seven point Likert-scale.
- *Business Risk perception* was measured by eight items relevant to the case as described by Simon et al (1999:131). Business risk perception refers to risk in the venture but excludes the potential personal risks to self and family associated with the decision to pursue the opportunity or not. Incorporating this element in the measurement would not be possible within the methodology used for this study.
- *Self-efficacy* was measured by eight items scored on a seven point Likert-scale as described by Markman et al 2002:165).
- *Misconceptions* was measured by twelve questions covering issues such as the overestimation of demand, underestimation of competitive response, underestimating resource requirements, misjudging managerial fit, cash flow and profit expectations. The large number of associated variables stems from the initial attempt to identify six misconception elements as constructs with three questions each.
- *Illusion of control bias* was measured by four items (three as described by Keh et al 2002:125). Qualifying questions were used to establish how strongly respondents want to establish their own businesses following the report of Markman, Balkin and Baron (2002:154).

Firstly the data was subjected to a factor analysis (BMDP program) to determine instrument stability, validity and whether it measured the constructs that it was intended for. Thereafter a correlation analysis was done to determine the strength of the correlations if such correlations exist and thirdly, analyses of variance was done to compare construct averages for groupings, language and start-up decision as biographical data.

## 5 FINDINGS

Table 1 reports the line number where the first thought of viability (or not) occurred while reading the case. It is important that over 80% of respondents decided before line 90/240 of the full case (excluding the financial projections at the end of the case). This finding supports the notion that heuristics (shortcuts) and biases were probably used in the decision. There was no significant difference for the mean line of 1<sup>st</sup> viability thought between those who decided to start and those not starting the venture.

---

Insert Table 1 near here

---

After rotation, four factors were observed in the data set with the factor analysis. These were named as shown in Table 2 and Figure 3.

---

Insert Table 2 near here

---

## 6 DISCUSSION OF THE FINDINGS

Figure 3 indicates a high negative correlation (-0,58\*\*) between business risk perception and the start-up decision and confirms the correlation reported by Keh et al (2002:19). Ho1 is therefore rejected and the correlation's direction indicates that if higher risk is perceived, support for taking the start-up decision diminishes. High or low business risk perception is, however, not causal to the decision but acts as a moderator of the decision.

The misconceptions showed a high correlation (0.49\*\*) with the start-up decision and therefore Ho2 is rejected. Displaying high misconceptions therefore leads to supporting the start-up decision and vice versa, again acting as a moderator of the decision.

It follows logically that if both risk perception and misconceptions are related to the start-up decision, there should be a correlation between them, which is confirmed by the high negative correlation (-0.49\*\*). Higher business risk perception therefore is associated with less misperception and vice versa. The fact that the factor analysis acknowledged them as separate measurements (constructs) recognises that they are different while the correlation indicated they are strongly related. The reason may be that both have a relationship with a third unknown construct not tested within this specific research questionnaire.

Insert Table 3 near here

---

Insert Figure 3 near here

---

Illusion of control bias, however, showed significant correlations with the decision to start (0.33\*\*), business risk perception (-0.34\*\*), misconceptions (0.41\*\*) but not self-efficacy (0.10). Ho3 is therefore rejected and it is accepted that such correlations do exist although the causality is not proven. Although the means between start-up and not start-up tended to be different it was not a significant difference.

Insert Table 4 near here

---

Insert Table 5 near here

---

Although the literature supports that self-efficacy plays an important role in human agency, the correlations between self-efficacy and the start-up decision (0.09), business risk perception (-0.05) and misconceptions (0.05) were all low and not significant. Ho4 is therefore accepted that self-efficacy has no apparent influence on the decision to start the venture. The question arises as to reasons for this? Possible reasons may include whether the instrument is a valid measure of self-efficacy. The measurement used, however, seemed accurate and in line with Kuratko and Whelsch (2001).

Alternatively it may be that no correlation was found because the self-efficacy construct response was not normally distributed as indicated by the mean of 5.927 on a seven-point scale leading to all respondents having a high level of self-efficacy. Kuratko and Whelsch (2001:176) suggest that self-efficacy plays an important role in the “intention” of the individual. Its effect may therefore be found earlier in the start-up process namely during the intent to start phase (see Figure 3). As self-efficacy influences behaviour it may also be more related to the start-up actions during implementation rather than the decision to start or not.

It was expected that the entrepreneurs / own business owners would mostly be the ones not starting the venture based on certain practical difficulties which would probably render the venture not viable. These practical issues (confirmed through expert panel) include the control of raw material quality, practical logistical inefficiencies of the transporting the product and the high dependence on employees who must control these key variables. While the entrepreneurial group reported the lowest misconceptions, highest business risk perception, lowest illusion of control bias and the highest self-efficacy, none of these differences were significant.

From those who chose not to start the venture, 34% reasoned that the opportunity was only a good idea and not really an opportunity while 15% thought the opportunity was not viable. Those who decided to start the venture reported the novel idea (37.5%) and the availability of the raw material (17%) as the main reasons for starting the venture.

## 7 IMPLICATIONS OF THE FINDINGS FOR RESEARCHERS

Can business risk perception and misconceptions, as relevant constructs for decision-making, be taught to potential entrepreneurs? While things like culture, education, previous experience, role models and thinking preferences influence perception; attitudinal aspects and lack of knowledge also influence misconceptions, there is a complex configuration of elements that play a role in the development of these heuristics and biases. Awareness of the impact may sensitise potential entrepreneurs to be on the look out for these potential contributors.

It was expected that business risk perception may be influenced by self-efficacy but this could not be confirmed in this study ( $r = 0.05$ ). The literature supports the role of self-efficacy on intention to start a venture but it appears not to play a role in the decision to start the venture.

The absence of a relation between the start-up decision and dominant thinking preference might be because alternative thinking preferences (application of whole brain thinking techniques) may mask the preferential thinking when faced with a decision of this magnitude. Ho5 could therefore not be tested based on the inability to meaningfully categorising individuals as having single dominant thinking preferences.

Illusion of control is a bias that refers to systematic preferences in cognitive patterning. The main focus of education should be on awareness and understanding of this bias and its impact on different thinking situations. Training in the identification of controllable and uncontrollable factors within the business environment as well as approaches and techniques to evaluate risk situations, can be of value.

## 8 LIMITATIONS AND FUTURE RESEARCH

Markman et al (2002:150) makes a case against the use of students when attempting to understand cognitions of entrepreneurs. In this study, however, the use of students seemed beneficial for the following reasons:

- They were not exposed to the entrepreneurial environment (real world) and few had any previous experiences in the field of entrepreneurship or business.
- Not having experience in the field might enforce the use of use of thinking heuristics, biases and information preferences as determined by thinking preferences.
- Gonzales, Lerch and Lebiere (2003:597) suggest that novices must engage in more thorough information searching to determine the principles that are applicable to the problem situation and that may benefit the study when compared to entrepreneurs with experience.
- Being forced to complete within an hour creates pressure that may enhance the use of heuristics and biases even further.
- Being forced to become entrepreneurs because there are no jobs available may indicate the existence of typical biases and misconceptions during the start-up decision and add to the pressure of the decision.

However, being at university already implies a selection process based on performance of the individual and probably indicates a privileged position within society that may influence the representativeness of the sample for the population. For example, the group representing the choice against entrepreneurship were all candidates with an exceptionally high M-score in matric (Grade 12 in secondary school) to get entrance to their specific course (medical related). They may therefore all have levels of self-efficacy.

Despite these limitations, the confirmed correlations have value for future research. The finding of specific misconceptions is one area that should be investigated further.

# **RISK MANAGEMENT IN FAMILY ENTERPRISES**

Walter Ruda, Thomas A. Martin

Kaiserslautern University of Applied Sciences, FH-Campus Zweibrücken, and German Center of Entrepreneurship ZMG, Amerikastraße 1, D-66482 Zweibrücken, Germany, Tel. +49-6332-914-240/-243, Fax: +49-6332-914-205, E-Mail: [ruda@bw.fh-kl.de](mailto:ruda@bw.fh-kl.de)

## **Abstract**

Numerous spectacular company crises in recent years have set off a broad discussion about the improvement of corporate governance, controlling systems and management in companies. In many cases, the crises are led back to internal causes, for example, missing or insufficient risk-controlling or no adjustment of the enterprises to its environment. The crises has not rarely been avoided by an early warning system of threaten developments or at least the negative results could have been weakened. This deficit has caused the action of the legislation in Germany. These considerations are written down in the Corporate Sector Supervision and Transparency Act (CSSTA), and started on may 1998.

More than the half of all german enterprises is established, run and essentially affected by family entrepreneurs. The term of family enterprise is defined different by means of one or more characteristics. It describes enterprises in the different legal forms and size and covers only partly with the term of small and medium-sized enterprises. A family enterprise can be characterized thereby that the majority of the participation is in the possession of a family or a specific number of families. Family enterprises show in comparison to not family-managed enterprises a series of differences. Specific risks of family enterprises which cause existence threatend crises in terms of the CSSTA are of high importance, especially crises of liquidity. The specific risks of family enterprises and the risk management system will be in the focus of the following article.

# **RISK MANAGEMENT IN FAMILY ENTERPRISES**

Kaiserslautern University of Applied Sciences, FH-Campus Zweibrücken, and German Center of Entrepreneurship ZMG, Amerikastraße 1, D-66482 Zweibrücken, Germany, Tel. +49-6332-914-240/-243, Fax: +49-6332-914-205, E-Mail: [ruda@bw.fh-kl.de](mailto:ruda@bw.fh-kl.de)

## **Introduction**

More than the half of all German enterprises is established, run and essentially affected by family entrepreneurs (Ruter and Thümmel 1994; Klein 2000; Franks and Mayer 2001). In the next years about 70.000 family enterprises with more than 0,51 million Euro annual turnover will be affected by a generation change (Martin and Martin 2002; Habig and Berninghaus 1998). According to experience only half of the enterprises are able to manage a successful transfer from the first to the second generation (Wimmer et al. 1996). But the crises of family enterprises are not only founded in the question of succession.

Numerous spectacular crises of enterprises in the past years have not only started a wide discussion in Germany about the improvement of controlling and management in enterprises. In many cases, the crises are led back to internal causes, for example, no adjustment of the enterprises to its environment or non-working internal controlling-systems. The crises has not rarely been avoided by an early warning of threaten developments or at least the negative results could have been weakened. This deficit has caused the action of the legislation in Germany. The results are written down in the Corporate Sector Supervision and Transparency Act (CSSTA), and started on May 1998 (Ruda and Pfeffer 2003).

The specific risks of family enterprises and the risk management system which was regulated in the CSSTA is in the focus of the following article. The superior goal of this article exists in having a share in the exploration of the features of risk management in family enterprises. Based on the targets of the CSSTA, in the first step risk management relevant legal revisions are worked out. In the second step the special characteristics of family enterprises are analysed because out of these specific threatened risks are resulted. The third step of analysis covers the arrangement of risk management systems in family enterprises. And at final, the risk management system is put in to the crises management and conclusions are derived.

## **The Corporate Sector Supervision and Transparency Act**

The CSSTA pursue the following aims: to correct weaknesses and conduct failure controlling in German supervision system in enterprises and the law of codetermination and to allow for information requirements of international investors. To reach these aims, the CSSTA contains among other things three new regulations. These are the obligation to establish a risk management system, to inform of risks of the future development in the management report as well as the expanse of the annual financial statement (Ruda 2005; Martin and Bär 2002).

The legislator obligates the management of stock-corporations by the new paragraph 2 of the §91 Companies Act to “take the right actions in particular to arrange a monitoring system in order that imperiling developments can be found early”. These are risks which have important influence on the financial situation, the financial position and the result situation. The risk management system consists of internal auditing, (risk) controlling and early warning system (Martin and Bär 2002; Lück 1998a).

Even though the obligation according to § 91 paragraph 2 Companies Act to arrange a monitoring system (risk management system) affects only stock-corporations, the legislator has also referred to the emission effects to the other legal forms, especially limited companies. But these effects are neither closer explained nor clearly concretized. In the result the obligation of risk management systems extends in general to all family enterprises in the legal form of a corporation and a KGaA but also to larger, differentiated limited companies and business partnerships thus to a huge part of the German medium sized enterprises (Hommelhoff and Mattheus 2000).

The second issue alludes to the obligation to respond to the risks of the future development in the management report (so-called risk report). The third reorganisation of the CSSTA affects also with the changes of the annual audit the named legal forms. It aims to an expansion and qualitative advancement of the annual audit and changed the following obligations of the German Commercial Code: the item and size of the audit (§ 317), the audit report (§ 321) as well as the audit certification (§ 322). During the audit it is to secure if the risks of the future development are correctly described in the management report. The § 317 paragraph 4 is of huge importance: The audit of stock quoted corporations checks if the management has made all decisions after § 91 paragraph 2 German Commercial Code correctly and if the arranged monitoring system can achieve its duties.

The risk management should be interpreted as the sum total of all activities to recognize and manage any imminent danger of loss. These might be individual or cumulative risks, including the interaction between these risks. It is the task of risk management to identify latent and potential risks at an early stage and to plan, control, and manage strategies and activities to counter them. The common duties of the risk management can be explained by means of the so-called risk management process which includes according to the general management process the following stages (Ruda and Leonhardt-Jacob 2005; Martin and Bär 2002; Lück 1998b):

- risk identification,
- risk analysis and quantification (e.g. risk portfolio, risk map),
- risk coping and
- risk monitoring.

The risk management process consists not only of a once-off-campaign but is carried out at regular intervals. This forms part of regular operational procedures and of the interplay between the operational units such as sales, marketing as well as the management board and also involves a coordinating risk management department which can be part of the controlling or the internal revision.

The risk management process has been preceded by thinking out a risk strategy, which basically contains the fundamental alignment of risk policy. The risk strategy provides rules of dealing with risks for each of the areas exposed to it. Its starting point is the general corporate strategy, from which the rules can be derived and integrated again into a strategy. Defining a maximum loss limit serves as the starting point for the corresponding risk-categories in the operational company departments.

## **Special structure characteristics of family enterprises**

The term of family enterprises is defined different by means of one or more characteristics and describes enterprises in the different legal forms and size (Klein 2000; Mugler 1998). It covers only partly with the term of small and medium-sized enterprises (SMEs).

A family enterprise can be characterized thereby that the majority of the participation is in the possession of a family or a specific number of families. In literature is also said that a factual critical (significant) effect of family members on the management is enough to speak of a family enterprise (Klein 2000; Gerke-Holzhäuser 1996). According to Ruter and Thümmel (1994) the following attributes characterize a family enterprise: The enterprise should be obtained as the professional/economic basic for family members over several generations, the owners are significantly represented in the management, the management consists of one person or a small group of persons, the personal relationship between owner/management and employees and the size of the enterprise is well manageable.

According to Löwe three characteristics define the term of family enterprise (Löwe 1979):

1. The significant amount of the capital is got together by the family.
2. One or more family deputies exert important effect on the management or they are even themselves in the management.
3. The investors have the target of obtaining the enterprise for the family (problem of succession).

Family enterprises can also be characterized besides the human identity of the management, the ring of shareholders and the alliance of the family by the participation of family members in the form of cooperation, financing, tenancy or leasing (Mugler 1998; Gerke-Holzhäuser 1996; Pichler et al. 1997). The definition happens insofar less on quantitative facts than on qualitative definition components like personality, charisma and emotion.

## **Specific risks of family enterprises**

Family enterprises show in comparison to not family-managed enterprises a series of differences (Duh 2002; Cromie and Stephenson 1995; Daily and Dollinger 1992; Goffee and Scase 1985; Hoy and Verser 1994). According to this article, specific risks of family enterprises which causes existence threatened crises in terms of the CSSTA are of high importance, especially crises of liquidity. In family enterprises the following reasons are existent for these risks: Personal deficits of managers (Ruter and Thümmel 1994; Feltham, Feltham and Barnett 2005), no effective controlling, planning and monitoring, unadjusted profit distributions (Habig and Berninghaus 1998), unregulated or abortive succession (Wimmer et al. 1996; Pichler et al. 1997), family conflicts (Klein 2000) and divergent life cycle of the family and the enterprise (Rosenbauer 1994).

Ruter and Thümmel differentiate in five basic risk fields: occurring gaps of management, unsolvable seeming follow-up regulations, an "aging" family patriarch, different interests between families which are drifting apart and unverified allocation politics. In literature there are mentioned also the lack of commercial orientation of the management, the lack of accomodation of the family enterprise and incomplete deed of association (Ruter and Thümmel 1994).

A central risk relevant characteristic of family enterprises is their specific life cycle. By the closely connection of the owning family (Stehle 1997) and the enterprise a mutual dynamic sampling of the owning family life cycle and the business life cycle can be noticed. There are the following life cycle conditional risk facts mentioned: the in the maturation phase defined growing chances in

common business for the second family generation, an arriving splitting of the enterprise with the effect of divergent objective targets and demands to the enterprise as well as the failure of the revitalisation (Rosenbauer 1994), obsolescence of the organisation, adherence to structures of the establishment phase, declining organisational and individual learning aptitude, declining vitality and innovation of the enterprise, a strong fixation on the maintenance instead on the extension of the lifework as well as the increasing splitting of the property with the danger of impasses and decreasing risk attendance (Goehler 1993).

### **Rating as a specific requirement of family enterprises**

The deregulation of capital markets, globalization, and the cutthroat competition within the banking world characterizes an upheaval in the traditional banking business, and as a result, the demand rises for adequate risk analysis and credit management. Banks must reckon with high bad debt loss and growing write-offs particularly in SMEs as well as family enterprises. The way banks allocate their credit should become more risk oriented with the systematic application of rating methods. The evaluation of the credit status, also known as risk analysis, takes place by a rating. Basel II equally affects, therefore, on the one-hand lenders and on the other creditors. SMEs, especially family enterprises, are not as familiar with the rating process in comparison to companies that are active on the capital markets (Arnold and Ruda 2002).

Special business risk factors that characterize family enterprises in comparison to non-family owned enterprises are reflected creditworthiness results. The following factors should be examined within the framework of the rating process for family enterprises (Martin, Ruda and Pfeffer 2003):

- Rating factor I: Insufficient financial flexibility

Mid-sized family enterprises are often not able to use alternative methods of financing such as those that the capital market offer in addition to the traditional means of financing through bank loans. A relationship of a company to only one financial institution is viewed critically (Ehrhardt and Nowak 2003). When questions arise about the creditworthiness of a company, they often, at least for short-term purposes, do not have further alternatives to financial support.

- Rating factor II: Insufficient transparency

Normally, family enterprises tend to be more restrictive in regards to the information released to other entities. The supply of information to external creditors and investors is in most cases limited to a minimum. Often enough, the partners of a company only have either insufficient or old information at their disposal. The lack of information provided in the rating process results in a negative effect on the rating notation, because not only do rating agencies expect open information and communication policies, so do the banks.

- Rating factor III: Strong personal dependency

A family enterprise is strongly characterized by the owner's characteristics, personality, and mentality, which causes a strong dependency relationship. In the examination from Klein (Klein 2000; Feltham, Feltham and Barnett 2005) it is shown that family enterprises less often have supervisory oversight of management in comparison to non family enterprises of the same size. Making the situation more difficult, family owned businesses tend to resist delegation of authority principles and the owner or management does often not take situations such as illness or death seriously.

- Rating factor IV: Low degree of diversification and company size

The business activity of family enterprises takes place as a rule in relatively small markets and/or market niches. Companies that concentrate on either a small product group, or for example only one product, and whose degree of diversification is small, have a higher risk factor in regards to rating

agencies in comparison to companies that have a wider product group and operate in numerous markets.

- Rating factor V: Disputes within the family or within the circle of partners

The emotional connection between family members or between partners often causes conflicts or disputes that considerably influence a company's business activities. When owners and managers differ in goal and value expectations, an objective analysis of the situation needs to take place in order to arrive at a consensus.

- Rating factor VI: The absence of company succession policy

The primary risk within family enterprises is the lack of a policy which outlines succession when something untowards occurs (Feltham, Feltham and Barnett 2005). Often enough when a successor takes over the company restructuring of the company occurs. Every year in Germany almost 2000 family enterprises go out of business due to the lack of a successor policy, or because an unplanned ownership change was too much for the successor to handle. The transfer of a company, however, is a step that not only has consequences for the previous owner, but also for the successor. Mistakes that can be traced back to bad planning cannot retrospectively be corrected and can have serious consequences for the successor.

- Rating factor VII: Absence of planning and information system

One of the main weaknesses of family enterprises lies within the lack of a strategic plan. Owners and managers of family enterprises are often overworked because they lack qualified personal to accumulate and interpret qualitative and quantitative data in order to adapt and implement new methods. Unlike large companies, family enterprises, in many cases, lack a written strategic plan outlining their visions and divided into long and short term. The strategy usually exists, although unfortunately only in the mind of the owner or manager.

- Rating factor VIII: Absence of an early warning system

Latent crises within partner or management circles such as sickness, old age, or death can only be identified in time with the existence of an early warning system. The recognition and analysis of oportunities and risks often occur too late in family enterprises. Nevertheless, many internal and external rating organizations, such as savings banks, take into consideration whether or not a risk management plan exists for the rating notation. Because of that, family enterprises should implement a formal risk management system as soon as possible in order to secure their credit supply.

---

## **Designing of risk management systems in family enterprises**

The special implementation of the risk management system depends on different influencing factors. The legislator names explicit the determinantes: "size of the enterprise, branch, structure and complexity of the enterprise and access to the capital market etc." But how must the family enterprise be organized after the CSSTA to confirm to the legal request of the management and the executive board? In doing so, in the foreground stand the components which have to exist as a minimum so if necessary an audit of effectiveness by an auditor which is the case by a stock exchange quotation (§ 317 paragraph 4 German Commercial Code).

In the frame of the risk identification the form of risks are to be systematised and documented. In literature a number of categories can be found such as value-creation, finance and management risks, strategic risks, risks of Corporate Governance, legal risks as well as political/social risks

(Ruda and Leonhardt-Jacob 2005; Martin and Bär 2002). For family enterprises the risks of Corporate Governance and the strategic risks are of high importance because these risks demand a closely monitoring and analysis as well as an evaluation. It can be derived from the personal identification of property and management in family enterprises that the affected family members on the one hand have the duty as a manager to provide a functional risk management system but on the other hand they are themselves a part of the risk management process.

For an objectivation of the risk identification, analysis and monitoring especially by the problem of an “aging” family patriarch a family external advisory board can be arranged to help (Ruda 2005; Ruda 1997; Ruter and Thümmel 1994). In the frame of the risk controlling as well as the risk accomplishment an advisory board can help, e.g. as an improver (Gratz 1997) or a mediator. Family enterprises can use the same strategies like non-family enterprises to accomplish risks: avoidance, decrease, assignment as well as balancing (Martin and Bär 2002). Ruter and Thümmel (1994) abstract the superior target of the risk management in family enterprises: protection for the family and protection of the family.

This crossover of family sphere and enterprise sphere demands in the stage of risk accomplishment specific management effort (Davis and Stern 1988; Mugler 1998): borders between management and family life, organization of resolution instruments of family problems, organization of “self-supporting” enterprise structure irrespective of open family issues and implementation of management systems which are resistant against extraordinary events and crises in the family. Thereto counts e.g. in detailed and customized deeds of association, detailed management agreements, organization charts (Pichler et al. 1997) and the assignment of external managers (Ruter and Thümmel 1994).

## **Conclusion**

The risk management system after CSSTA is an instrument of the preventive crisis management which has the task to early recognize the existence of endangering developments. Therefore the latent and potential risks are subjects of the risk management system. Especially the potential crises have the highest methodical requirements to the early warning system. The management of the crisis is not included in the duty of carrying of the management recording to § 91 paragraph 2 Companies Act.

The crisis management includes the task of taking actions to prevent the occurring crisis and to manage the occurred crises (Krystek 1987). These findings show that the CSSTA is not sufficient for a successful management of crisis in family enterprises because an entire management of crisis runs beyond an early identification and lasts for the stages of risk management and/or risk acceptance.

According to § 317 paragraph 4 German Commercial Code the auditor judges if the management has taken the right form of early risk identification and if the monitoring system can fulfil its tasks. The auditor has to judge the implemented risk management system of its function. This presupposes a written documentation, e.g. in the form of a risk-handbook. Therefore the audit is limited on the risk identification but not on activities for the coping.

Besides the legal requirements the risk management has the task of finding and converting strategies for the management of risks. There are the following alternatives: risk avoidance, risk decrease, risk transfer and risk compensation (Lück 1998).

It is now necessary to extend the risk management system beyond the early identification, so that it can support the entire risk management. The requirements of the detailing and formalisation degree of the risk management system interact with the size of the enterprise. In smaller family enterprises the management have the duty to arrange a functional early risk identification system of controlling,

early warning and internal revision. Regarding the discussions about ratings and risk adequate credit interests in consequence on BASEL II also family enterprises have to think about an implementation of a risk management system if they are not included in the CSSTA.

## **An Examination of the Legitimacy Lie**

### **Abstract**

To survive, entrepreneurs in start-up companies must overcome liabilities of newness and smallness to gain legitimacy in the eyes of key stakeholders, primarily customers and financial providers. Prior research and theory suggests that entrepreneurs will likely employ proactive strategies to gain legitimacy with these key stakeholders. These proactive attempts to gain legitimacy may lead to questionable ethical behaviors, including intentional misrepresentations of the facts. In this paper we apply common ethical frameworks to explore the boundaries of what may or may not be acceptable behavior in seeking legitimacy and offer some guidelines for entrepreneurs.

## **INTRODUCTION**

Many researchers have noted that overcoming the liabilities of newness and smallness are the most difficult challenges that a young SME owner/manager encounters (Singh, Tucker, and House, 1986). These challenges can be essentially described as a quest for legitimacy for the SME. Until stakeholders view the SME as a legitimate enterprise, the owner/manager will have great difficulty acquiring the resources (e.g. capital, employees, and supplies) that the enterprise needs to survive. As a result, many owner/managers feel that they must employ whatever strategies and tactics necessary to overcome these liabilities and gain legitimacy. Since most small firms are “opaque” with regard to information—meaning that it is difficult for outside participants to ascertain the quality of a given venture—it is especially tempting and possible for owner/manager’s to mislead social actors. This problem is compounded in many new ventures because entrepreneurs have an advantage of information asymmetry - they know more about certain aspects of the business (e.g., intellectual property) than outside stakeholders.

In this paper, we hold that there exists an initial threshold in most firms where, before the threshold young SMEs have high levels of smallness and newness liabilities, and after this threshold these liabilities have been mitigated significantly. In most firms this threshold occurs when some significant stakeholder has legitimized the firm. At early stages of development, because young SMEs are cash starved, it is most often a key customer or financier that grants this legitimacy. Once this legitimacy has been granted, a signal is sent to other stakeholders that the firm is something more than an untenable collection of resources and is worthy of some level of trust—legitimacy begets legitimacy.

This condition causes most young SME owner/managers to face a simple ethical conundrum: how to send the signal of legitimacy when, by definition, the organization is not legitimate? No social judgment of appropriateness has been made regarding the organization, yet the organization must appear as if it has. Stories abound in which an aspiring entrepreneur set up a “sham” operation to convince a prospective stakeholder that the organization was something more than it, in fact, was. Similarly, stories exist where an entrepreneur makes promises that he or she is not sure can be delivered upon. In a strict interpretation these are lies—misrepresentations of the truth. These lies ultimately result in violations of trust between the owner/manager and his or her stakeholders.

The purpose of this paper is not to solve this ethical debate by playing “morality police”, for there may be no simple answer. However, there are a number of ethical frameworks available to help an owner/manager navigate this potentially slippery slope. We will first address the specifics of the legitimacy lie with both legitimacy and ethics theory bases, along with a number of examples from the literature and our experiences. Next we will explore, broadly, the nature of entrepreneurial ethics with a special focus on the unique nature of ethical issues in the small firm. We then present corresponding ethical frameworks that are appropriate for dealing with this issue. We conclude with some general guidelines for entrepreneurs.

## **THE LEGITIMACY LIE**

The definition of this construct lies at the intersection of legitimacy theory and ethics theory—more specifically, at the intersection of SME legitimacy theory and ethics theory pertaining to

lies. It essentially involves lies told before legitimacy is attained for the purpose of reaching legitimacy. These are generally statements made or actions taken to counteract the liabilities of smallness and newness that most entrepreneurs feel are unfairly placed on them by stakeholders. The legitimacy lie is defined here as an entrepreneur's "knowing misrepresentation of the facts" in an effort to encourage various stakeholders to deem them as a legitimate entity. The most common stakeholders misled at this early stage are customers and financiers. This is simply because these groups are the most critical at the early stage of a SME's life (Jawahar and McLaughlin, 2001).

In finance parlance, this is called moral hazard, and as the term suggests, it is viewed negatively by this stakeholder group. This is relatively straightforward for traditional financiers, such as banks, because they generally quantify this as a credit score based on the owner/manager him or herself (??).

### Legitimacy Threshold

Legitimacy is defined parsimoniously here as: "...a social judgment of acceptance, appropriateness, and desirability, [that] enables organizations to access other resources needed to survive and grow." (Zimmerman and Zeitz, 2002). The legitimacy threshold (LT) is based on punctuated equilibrium theory, which essentially holds that large-scale change in organizations is discontinuous, abrupt, infrequent, and noticeable. An organization being initially legitimized is usually such a change. Punctuation occurs in response to a major environmental change, called a trigger. The trigger is the key component pushing a given system over its threshold of stability (Tushman, Newman, and Romanelli 1986). With regard to the legitimacy threshold, the trigger is usually a major stakeholder (customer, financier) legitimizing the organization. Once the substantial environmental change of legitimization takes place, the organization moves from begging for a certain resource to managing that resource.

Zimmerman and Zeitz (2002) were the first to explicitly use and operationalize the legitimacy threshold. They define the LT as: "[The point] below which the new venture struggles for existence and probably will perish and above which the new venture can achieve further gains in legitimacy and resources." They go on to state: "An organization must achieve a base level of legitimacy that is dichotomous—it either does or does not meet the threshold" (Zimmerman and Zeitz, 2002). In life cycle parlance, the LT can be thought of as a firm moving from the birth stage to at least the potential for the growth stage. Scott and Bruce (1987) term this the "inception to survival crisis".

It is worth mentioning an alternative here. Based on our preliminary research, all SGEs will not encounter a threshold. For example, two entrepreneurs we spoke with did not feel that any one event forced them to restructure. One purchased a number of struggling restaurants and simply "tweaked" the system to grow. Another received venture capital financing in the "pre-birth" stage and was able to grow relatively seamlessly. Relatedly, just because a given firm made to the LT does not mean that cannot or will not fall back below it—an important customer could easily "fire" the company (Rutherford et al????).

### Legitimacy Lies

As noted, we define the legitimacy lie as an entrepreneur's "knowing misrepresentation of the facts" in an effort to encourage various stakeholders to deem them as a legitimate entity. By knowing misrepresentation of the facts, we mean not only the actual conveying of information or other kinds of meaningful communication (e.g., actions) in a manner intended to deceive, but also the deliberate withholding of information or other kinds of meaningful communication that might, if conveyed, lead a stakeholder to correct a mistaken assumption, conclusion or impression. Some examples are shown in Table 1.

### **Ethical Frameworks**

There are a great number of ethical frameworks that can be applied to the legitimacy lie problem. For the sake of parsimony, we will contrast two well-known general theories, *utilitarianism* and *deontology*, and demonstrate how they apply. The following discussion is based on the work of Spitzer, 2000; 2003).

Utilitarianism focuses on harms and benefits associated with certain actions. The general principle can be summarized by the statement: "if the consequences of a particular action produce more harm than benefits, that action should be avoided" (Spitzer, 2000, p. 207). Thus, utilitarians judge the rightness or wrongness of actions based on the outcomes of those actions - whether they lead to more good than harm. They do not see particular actions by themselves as being either intrinsically good or bad. For example, lying or cheating may be acceptable if it can be determined that doing so results in little or no harm relative to its positive consequences.

While utilitarianism has been widely applied in business ethics, there are several potential problems with its use. For example, it is often difficult to evaluate objectively the potential harms and benefits stemming from an action. Moreover, utilitarians' use of quantitative assessment of outcomes tends to focus more on quantity than gravity. There is a great deal of ambiguity and subjectivity in evaluating so-called "objective" outcomes. Thus, utilitarians are often prone to rationalization when weighing harms and benefits.

On the continuum of ethical theories, deontology is the polar opposite of utilitarianism. Deontology posits that there are certain inviolable duties or principles "to promote an intrinsic or objective good, and to avoid an intrinsic or objective evil" (Spitzer, 2000, p. 210). On the positive side, deontologists associate ethical behavior with certain acts like honesty, fairness, and justice; on the negative side, they associate unethical behavior with acts like lying, cheating, stealing, being unfair, or causing unnecessary harm (Spitzer, 2003, p.2). The distinguishing mark of deontology, as opposed to consequentialism, is that actions by themselves are intrinsically good or bad, *regardless* of their consequences. For example, deontologists would say that lying is wrong and should be avoided. Further, they hold that the end does not justify the means. Thus, a person cannot justify using a wrong (e.g., lying) to accomplish a beneficial end (e.g., obtaining financing for a start-up company, and thus creating jobs). Of course, deontologists recognize that there are situations in which a person faces a choice between two evils (e.g., layoffs versus going out of business). In these situations it is permissible to use an evil means to avoid an even greater evil end (Spitzer, 2003, p.3).

## Ethics and the Legitimacy Lie

Based on the discussion above, we propose the model in Figure 1 as a framework for evaluating the ethics of the legitimacy lie. The framework has two dimensions: misrepresentation of the facts, either knowing (intentional) or unknowing (unintentional) and consequences for stakeholders, either positive or negative. Figure 1 provides frameworks illustrating both the utilitarian and deontological ethical theories. Using these models, there are four general possibilities regarding legitimacy lies:

1. Knowing misrepresentation that leads to positive outcomes for the stakeholder
2. Knowing misrepresentation that leads to negative outcomes for the stakeholder
3. Unknowing misrepresentation that leads to positive outcomes for the stakeholder
4. Unknowing misrepresentation that leads to negative outcomes for the stakeholder

---

### Figure 1 About Here

---

As shown in both ethical frameworks, unintentional misrepresentation of the facts (quadrants III and IV) is generally not an ethical violation. In these cases, the entrepreneur may unknowingly misrepresent the facts of the company, perhaps through her or his high level of enthusiasm, self-confidence, or the lack of skills or information, or simply due to errors. The historical lore is replete with stories of entrepreneurs who “over promised” and eventually delivered through their supreme self-confidence, hard work, ingenuity, and persistence. Two caveats in these cases should be considered, however. First, overconfidence and the tendency to “over promise” may be rooted in an entrepreneur’s lack of self-knowledge, or an unrealistic assessment of the facts in the situation (e.g., lack of due diligence), or negligence leading to inaccuracies. In these cases, one could argue that the entrepreneur is “out of touch” with reality, or careless, and should therefore should be held ethically accountable for misrepresenting the truth. Second, misrepresenting the truth, even unknowingly, may have implications for trust in the relationship with the stakeholder involved, especially when the consequences are negative. In this case, the stakeholder will likely not trust the entrepreneur who, in his or her exuberance, has misrepresented the facts, unless the stakeholder truly believes that the entrepreneur has acted in good faith. If the stakeholder in the relationship believes the entrepreneur has not intentionally been misleading, she or he may be willing to give the entrepreneur a second chance in the relationship.

With respect to knowing misrepresentation of the facts, the deontological model considers this behavior as unethical in all cases (quadrants I and II). The utilitarian model considers intentional misrepresentation as a violation if it leads to negative outcomes (quadrant II), but not if the consequences are positive (i.e., more benefits than harms, quadrant I). Several caveats should be noted with respect to knowing misrepresentation. First, as noted earlier, evaluating harms and benefits in the utilitarian approach can be very ambiguous and subjective and may lead to rationalization. Second, even though utilitarian logic suggests that an entrepreneur’s deliberate lying to a financier (e.g., company financial status) can be ethical when it leads to more benefits than harms (e.g, financing allows the company to survive and ultimately hire more employees), this situation may have a long-term negative impact on the level of trust between the entrepreneur and a stakeholder. If the stakeholder, a financier in this case, discovers the

intentional deception, and especially, if she or he has a deontological perspective, the stakeholder will likely perceive the entrepreneur as being untrustworthy. Moreover, even if the financier in question does not know about the deception, perhaps other stakeholders do, such as the entrepreneur's partners or employees. These other stakeholders may consider the entrepreneur as untrustworthy, affecting the long-term quality of their relationship with the entrepreneur.

Applying the models in Figure 1 to some of the examples in Table 1 will help illustrate the ethical considerations regarding legitimacy lies. Example E states: "When customers called, I would tell them 'Steve is in the warehouse', which meant the garage." While relatively minor, this intentional deception would be viewed as unethical according to deontological logic. However, assuming that no harm was done by the deception, and that it lead to positive outcomes with customer perceptions and eventual sales, it could be viewed as ethical by utilitarian logic. Example I explains: "No space in the apartment - I always met people at the airport -- said I was leaving on a flight, then waited until they had gone to go back home." Again, this rather minor misrepresentation would be viewed as being unethical from a deontological perspective, but acceptable using utilitarianism, provided that the benefits to stakeholders outweighed the harms. Several other examples (A, B, C, G, and H) are ambiguous as stated. It is not clear in these attempts to make ones' company "look bigger than it is" are actually deceptions. There is nothing inherently wrong with an entrepreneur or a new venture "putting their best foot forward." For example, using glossy brochures and a company logo are not necessarily misrepresentative, but rather could be considered as wise investments in demonstrating the quality, professional approach, and potential of the company. However, under deontological theory, any deliberate misrepresentation of the facts, however communicated, is unethical, while under utilitarianism, deliberate misrepresentations of the company could be seen as ethical so long as the results for stakeholders are more positive than negative.

## Conclusions

In this paper we have argued that entrepreneurs in start-up companies must overcome liabilities of newness and smallness to gain legitimacy in the eyes of key stakeholders, primarily customers and financial providers. Such legitimacy is crucial if start-ups are to survive and have the potential for moving into the growth stage. Further, descriptive stakeholder theory (Jawahar and McLaughlin, 2001) suggests that entrepreneurs will likely employ proactive strategies to gain legitimacy with these key stakeholders. These proactive attempts to gain legitimacy may lead to questionable ethical behaviors. The academic literature regarding ethics and entrepreneurship, especially with respect to legitimacy issues, is not well-developed. We have attempted to apply common ethical frameworks of utilitarianism and deontology to explore the boundaries of what may or may not be acceptable behavior in seeking legitimacy.

Our analysis concluded that, regardless of which ethical framework is used, unknowing misrepresentation of the facts in seeking legitimacy is generally ethical. There may be some ethical questions in cases where the entrepreneur has not done adequate due diligence in gathering the facts, has made careless errors, has "overpromised" due to an unrealistic self-understanding. However, many entrepreneurs have high levels of self-confidence and enthusiasm and do ultimately achieve goals that many stakeholders might deem as unattainable.

Indeed, this outcome is one of the attributes that we associate with and endear people to successful entrepreneurs. Knowing misrepresentation of the facts, on the other hand, is always unethical from a deontological perspective because such acts are intrinsically wrong. From a utilitarian perspective, knowing misrepresentation is clearly unethical when it leads to more harm than benefits, but may be acceptable when it can be determined that the benefits of doing so outweigh the costs. Of course, we have pointed out that utilitarian logic can be problematic because evaluation of harms/benefits is often subjective and there is a tendency to rationalize and justify unethical behavior. We have also argued that deliberately misrepresenting a company's products or finances, even when this leads to positive outcomes, may cause a lack of trust between an entrepreneur and various stakeholders.

We believe that the models in Figure 1 can provide a useful framework for examining the ethical ramifications of an entrepreneurs' attempts to gain legitimacy. First, entrepreneurs should make every effort to gather appropriate and accurate information (e.g. product, financial, operations, etc.) as they represent their venture to various stakeholders. Second, entrepreneurs would benefit by careful reflection about their own and their company's strengths and weaknesses. Realistic self-awareness and more thorough knowledge of the company and its capabilities may moderate the tendency of entrepreneurs to over sell or over promise. Of course, we are not suggesting that entrepreneurs tone down their vision, enthusiasm, and self-confidence. We argue only that entrepreneurs can potentially make more ethical choices if they are more consciously aware of themselves and their ventures. Third, we argue that, while possibly acceptable under utilitarianism, deliberate misrepresentations of the facts to stakeholders may be problematic. Entrepreneurs should exercise caution in assessing costs and benefits of their actions and be cognizant of the tendency for rationalization. Even when these so called "white lies" produce more benefits than harms, they may ultimately undermine the trust in relationships with stakeholders. In addition, prior to taking action, it would be useful for entrepreneurs to consult with advisors or others about potential ethical issues. It may also be beneficial to establish a core set of values and ethical principles to guide the new venture from its inception. In the final analysis, the entrepreneur is responsible for both the ethics of the choices she or he makes in attempting to gain legitimacy and also for the long-term consequences of those decisions.

## **Abstract:**

For most of the 20<sup>th</sup> century entrepreneurial activity declined in almost all Western countries. However, by now it is a well established fact that entrepreneurship has increased in many of the modern economies since the 1970s onwards. Some authors have identified a U-shaped relation between entrepreneurial activity and economic development. Several phenomena explain this reversed trend. Arguably the most important explanation for the rise in entrepreneurship at higher levels of development is a shift in the technology regime. In this paper we develop a theoretical model that explains the U-shaped relationship in a formal way as the result of a technology regime shift that is brought about by the introduction of a new general purpose technology (GPT). The derivation of the theoretical model is followed by some preliminary empirical exercises which introduce a new direction of research trying to identify when these regime shifts manifest themselves in different countries. The preliminary exercises also try to identify which countries are technological leaders and which countries are technological followers.

## INTRODUCTION

Kuznets (1971), Schultz (1990) and Yamada (1996) have shown that a negative relationship between economic development levels (usually proxied by time or GDP per capita) and entrepreneurship (proxied by private business ownership) exists for a large cross-section of countries. Lucas (1978) and more recently Chandler (1990), Schaffner (1993), and Iyigun and Owen (1998) have provided models that generally explain this stylised fact as the result of increasing opportunity costs to entrepreneurial activity. Wages in employment rise and become less risky, asymmetric information problems decline and economies of scale and scope become more important as an economy grows.

Recent empirical evidence for the OECD, however, (Carlsson (1989), Loveman and Sengenberger (1991), Acs et. al. (1994), Acs (1996), Thurik (1999)) has shown that that negative correlation may have been reversed recently and Carree et. al. (2002) argues that the relationship may in fact be U-shaped. Carree et. al. (2002) presents some loose theoretical considerations to explain such a pattern in the data.

The rise in entrepreneurship at higher levels of development is attributed to a shift in the technology regime, from accumulative to radical innovation, from Schumpeter Mark II to Schumpeter Mark I. That shift increases the risks (unemployment, job displacement) in established industries and the returns to entrepreneurship in new sectors. In addition technological, institutional and cultural factors all seem to have shifted in favour of entrepreneurship, although it is unclear that these trends are inextricably related to economic development. Finally the authors also cite Schiller and Crewson (1997) and Kirchoff (1996) who argued that part of the revived interest is an income effect. They base their claim on the argument that entrepreneurship can be regarded as consumption because it allows persons to achieve self-realisation at the top of the Maslowian (1970) hierarchy.

In this paper we develop a model that explains the U-shaped relationship in a more formal way as the result of a technology regime shift that is brought about by the introduction of a new GPT (general purpose technology). We then test the predictions of that model using the COMPENDIA dataset which includes 23 OECD countries. The model builds on the model of skill bias in Sanders (2004). In that model the introduction of a new GPT allows entrepreneurs to quickly develop new ideas and consequently more effort is allocated to entrepreneurial R&D. Economic growth, predominantly resulting from variety expansion, is then the result of higher entrepreneurial activity. Under the Schumpeter Mark I regime the causality therefore runs from entrepreneurship to growth.

Under the Mark II regime, when the effect of the GPT has petered out and innovative efforts switch (back) to the development of cheaper and more efficient production methods, entrepreneurial R&D declines. Further economic growth is now caused by higher efficiency in the production of existing varieties, which drives up wages and returns to firm based R&D, causing a negative correlation between entrepreneurship and income. Here the causality runs the other way, from income levels to entrepreneurial activity.

The empirical analysis in this paper will focus on the relationship between income and entrepreneurial activity. The exercises are meant to illustrate how the theoretical concepts developed in the model may manifest themselves in economic reality.

## THE MODEL

Before turning to the actual modelling of entrepreneurial activity it is useful to set up a standard general equilibrium model with consumers and producers. Such a model sets the stage. The role of entrepreneurs in our model is then to develop and commercially introduce new goods and services. As producers they then start producing these new products. We assume a product life cycle, which implies that in the initial stages the new product can only be produced using skilled labour (see Audretsch (1987) and Xiang (2002) for evidence). The producer may then decide to develop the production process in such a way that cheaper resources, i.e. low skilled labour, can be employed. As both start-up firms and established firms need engineers to develop their prototype and new production lines respectively, we assume for simplicity that entrepreneurs and incumbents compete for the same R&D resources. The share of total R&D resources allocated towards new goods creation then corresponds one for one with the level of entrepreneurial activity properly defined. The next section will then translate the theoretical predictions of the model into testable hypotheses and confront the model with the data.

### Consumers

The model presented below will follow standard variety expansion endogenous growth models closely.<sup>1</sup> First infinitely lived consumers save and consume in a standard fashion to maximise lifetime utility subject to a budget constraint. The problem is given by:

$$\max_{C(t)} : U = \int_0^{\infty} e^{-\rho t} \log C(t) dt \quad \text{s.t.} \quad Y(t) + rA(t) = C(t) + \dot{A}(t) \quad (1)$$

where  $\rho$  is the subjective discount rate and  $C(t)$  is a consumption index to be defined below. Defining  $E(t)$  to be the expenditure on consumption at time  $t$  and  $P(t)$  the minimum price of one unit of the index, we obtain the standard Ramsey optimal savings rule:

$$\frac{\dot{C}(t)}{C(t)} \equiv \frac{\dot{E}(t)}{E(t)} - \frac{\dot{P}(t)}{P(t)} = r - \rho \quad (2)$$

Utility maximisation implies maximisation of the consumption index for any given level of expenditure in any period. A Dixit-Stiglitz love of variety consumption index is therefore maximised in every period subject to the intratemporal budget constraint:

$$\max_{c(i)} : C = \left( \int_0^n c(i)^\alpha di \right)^{1/\alpha} \quad \text{s.t.} \quad \int_0^n p(i)c(i)di \leq E \quad (3)$$

where  $c(i)$  is the volume and  $p(i)$  is the price of variety  $i$  consumed and time arguments have been dropped to save on notation. The first order conditions to this problem show that the intra-temporal consumption index is maximised by setting demand for an individual variety equal to:

$$c^D(i) = \left( \frac{p(i)}{P} \right)^{\frac{1}{\alpha-1}} \frac{E}{P} \quad (4)$$

where  $P$  is again the price index, earlier defined as the minimum price of a unit of the index:

$$P \equiv \frac{E}{C^*} = \left( \int_0^n p(i)^{\frac{\alpha}{\alpha-1}} di \right)^{\frac{\alpha-1}{\alpha}} \quad (5)$$

where  $C^*$  is the maximum value of the consumption index given expenditure  $E$  and prices  $p(i)$ . Consumers therefore save and consume yielding an iso-elastic demand curve for all varieties. This set-up allows for variety expanding R&D investments as they can be financed up front out of savings and are worthwhile to undertake as new goods face a positive demand at any price.

## The Producers

Now we turn to the producers in the model. Assume monopolistic competition between firms that produce one variety each. Their profit maximisation problem is now given by:

$$\max_{p(i)} : \pi(i) = y(i)p(i) - tc(i) \quad \text{s.t.} \quad y(i) = c^D(i) \quad (6)$$

where  $y(i)$  is the volume and  $tc(i)$  the total costs of production for variety  $i$ . It can easily be verified that to maximise profits producers must set prices equal to a fixed mark-up,  $1/\alpha$ , over marginal costs. To introduce the product life cycle at this stage assume that at any point in time there is a range of new,  $n_H$  and a range of mature goods,  $n_L$ , that are produced with high and low skilled labour, respectively. Assume in both ranges the production function is given by:

$$y_S^D(i) = b_S l_S(i)^\beta \quad \forall i \in n_S \quad (7)$$

where  $S=\{H, L\}$  indexes high and low skilled varieties. Facing the same demand function, competing for the same labour and restricted by the same production technology, within ranges firms will choose to employ the same quantity of labour and supply the same amount of products. That also implies that prices are set equal within ranges, as marginal costs are a function of the wage and employment levels. Setting production equal to consumption at profit maximising prices, inverting the production

function and aggregating over the two goods ranges yields the aggregate labour demand functions:

$$L_S^D = \frac{\alpha\beta}{w_S} E_S \quad (8)$$

where  $E_S$  is the total expenditure on varieties in range  $n_S$ . Using  $-S$  to signify “not- $S$ ” these expenditures can be written as:

$$E_S \equiv \left( 1 + \left( \frac{n_{-S}}{n_S} \right) \left( \frac{w_{-S}}{w_S} \right)^{\frac{-\alpha\beta}{1-\alpha\beta}} \left( \frac{b_{-S}}{b_S} \right)^{\frac{\alpha}{1-\alpha\beta}} \right)^{-1} E \quad (9)$$

From Equation (8) one can then derive relative labour demand in function of relative wages. It is given by:

$$\frac{L_H}{L_L} = \frac{n_H}{n_L} \left( \frac{b_H}{b_L} \right)^{\frac{\alpha}{1-\alpha\beta}} \left( \frac{w_H}{w_L} \right)^{\frac{-1}{1-\alpha\beta}} \quad (10)$$

And profits per variety are given by:

$$\pi_S(i) = (1 - \alpha\beta) E_S / n_S \quad \forall i \in n_S \quad (11)$$

Note that stable market shares imply that profits per variety fall with the number of varieties in a given range. Cost minimisation yields iso-elastic aggregate demand curves for both types of labour in the model while imperfect competition allows producers to make positive profits and repay their up front R&D investments that are discussed below.

### Labour Market Equilibrium

For given relative employment levels Equation (10) can be rewritten to trace out a concave upward sloping curve in  $n_H/n_L$ - $w_H/w_L$ -space. With inelastic exogenous labour supplies this curve represents the labour market equilibrium in the short run and therefore also in the steady state. Below it will be referred to as the Product Market Arbitrage or *PMA*-curve as it equates the relative marginal product of labour in production to the relative wage. This curve is constructed graphically in Figure 1.

[Figure 1 about here]

In the right panel the labour market is depicted. An exogenous relative supply is equated to a relative demand that is conditional on  $n_H/n_L$ . Two relative demand curves have been drawn and were labelled  $Z_1$  and  $Z_2$ , where  $Z_2$  represents a higher ratio of  $n_H/n_L$ . By plotting the equilibrium wages against the corresponding values for  $n_H/n_L$  one obtains the

*PMA*-curve in the left panel. Intuitively this curve is upward sloping as the employment level *per variety* is negatively related to the relative number of varieties per range and therefore positively to the relative marginal value product.<sup>2</sup> The figure also illustrates the impact of an increase in relative labour supply. For every  $n_H/n_L$  the relative wage now drops. Consequently an increase in relative supply,  $L_H/L_L$ , will cause the *PMA*-curve to rotate down and to the right as is illustrated in the left panel.<sup>3</sup>

So far the model has closely followed the models by for example Grossman and Helpman (1991a) and Acemoglu (2002). As in these models we can now introduce entrepreneurial activity in the form of adding new varieties to the range of new goods. Also firms are allowed to invest in maturing their production process such that low skilled labour can be employed.

### The Value of Innovations

Assume that innovations can be patented and patents are perfectly enforced or alternatively secrecy or tacit knowledge prevent others to copy a new product or process. In general the value of an innovation is then equal to the discounted (expected) real profit flow that can be generated by it:<sup>4</sup>

$$\frac{v_S(t)}{P(t)} = \int_t^{\infty} e^{-r(t-\tau)} \frac{\pi_S(\tau)}{P(\tau)} d\tau \quad (12)$$

where  $v_S$  denotes the value of the patent establishing a new good in variety range  $n_S$  and argument  $i$  has been dropped due to symmetry within the ranges. Equation (12) can be rewritten if we assume constant (expected) growth rates for profits and the price index:

$$v_S(t) = P(t) \frac{\pi_S(t)}{P(t)} \int_t^{\infty} e^{-(r-\dot{\pi}/\pi+\dot{P}/P)(t-\tau)} d\tau = \frac{\pi_S(t)}{r - G_{\pi_S} + G_P} \quad (13)$$

where  $G_X$  is the growth rate of  $X$ . When there is a product life cycle, however, the pricing of patents is a bit more complex. New products become mature when the production process is changed to allow low skilled labour to step in. I will assume, however, that the product specifications do not change in that transition. For future reference I therefore label the invention of a new product “product innovation”, while referring to the creation of a new process that matures an existing product as “process innovation”. The former activity is entrepreneurial R&D, the latter is incumbent R&D.

When a process innovation now moves a variety from the high to the low skilled range of goods, the profit flow for the incumbent firm increases. The value of a process innovation therefore equals the positive *difference* between the present value of the new and that of the mature product’s flow of rents. The value of a product innovation remains given by (13). One thus obtains:

$$v_H(t) = \frac{\pi_H(t)}{r - G_{\pi_H} + G_P} \quad \text{and} \quad v_L(t) = \frac{\pi_L(t)}{r - G_{\pi_L} + G_P} - \frac{\pi_H(t)}{r - G_{\pi_H} + G_P} \quad (14)$$

## The Production of Innovations

To close the model we need to specify how Entrepreneurial and Incumbent Firms' R&D results in actual product and process innovations, respectively. Consider the following production functions for Entrepreneurial and Incumbent Firms' R&D:

$$\begin{aligned}
 \dot{n} &= n a_E R_E^\gamma \\
 \dot{n}_L &= n_H a_I R_I^\gamma \quad \text{where} \quad 0 < \gamma \leq 1 \\
 n_H &\equiv n - n_L \\
 \dot{n}_H &= \dot{n} - \dot{n}_L
 \end{aligned} \tag{15}$$

Note that in a product life cycle specification any addition to range  $n_L$  implies a reduction in range  $n_H$  and only Entrepreneurial R&D can increase the total number of varieties,  $n$ .  $R$  is the amount of R&D labour allocated to Entrepreneurial,  $R_E$ , and Incumbent Firms',  $R_I$ , R&D, respectively.<sup>5</sup> The number of total and new varieties proxy for knowledge that is productive in Entrepreneurial and Incumbent Firms' R&D activity, respectively. Such knowledge spillovers are what drive any endogenous growth model.<sup>6</sup> Note also that, despite the aggregate increasing returns to scale, this specification allows for diminishing returns to R&D resources by allowing for  $\gamma \leq 1$ .

A competitive R&D sector now allocates the available R&D workers,  $R^*$ , between entrepreneurial and incumbent activities to maximise profits by setting:

$$\frac{R_E}{R_I} = \left( \frac{n_H}{n_L} \right)^{\frac{1}{\gamma-1}} \left( 1 + \frac{n_H}{n_L} \right)^{\frac{-1}{\gamma-1}} \left( \frac{v_L}{v_H} \right)^{\frac{1}{\gamma-1}} \left( \frac{a_E}{a_I} \right)^{\frac{1}{1-\gamma}} \tag{16}$$

The R&D sector thus produces a flow of product and process innovations by employing all available R&D resources and using the public knowledge base accumulated in the past. R&D can be financed using savings as long as the return on R&D investments exceeds or equals the subjective discount rate.

## The Steady State Equilibrium

Now consider the conditions for a steady state equilibrium. For a given relative supply of high over low skilled labour Equation (10) shows that a stable ratio  $n_H/n_L$  implies stable relative wages. Stable relative wages imply stable relative profits, which in turn imply stable relative patent values. Stable relative patent values and a stable ratio  $n_H/n_L$  yield a stable allocation of R&D resources that can produce stable growth rates for the two ranges of goods. Hence a stable ratio  $n_H/n_L$  is the first condition for a steady state equilibrium. That implies:

$$\frac{\dot{n}}{n} = \frac{\dot{n}_H}{n_H} = \frac{\dot{n}_L}{n_L} \tag{17}$$

using Equation (15) that condition also implies for the steady state allocation of R&D labour that it must satisfy both Equation (16) and:

$$\frac{R_E}{R_I} = \left( \frac{n_H}{n_L} \right)^{\frac{1}{\gamma}} \left( \frac{a_E}{a_I} \right)^{\frac{-1}{\gamma}} \quad (18)$$

Setting this expression equal to Equation (16) and solving for relative wages yields a steady state relationship between relative wages and  $n_H/n_L$  that, together with the *PMA*-curve, determines all feasible steady state equilibria:<sup>7</sup>

$$\frac{w_H}{w_L} = \left( \frac{b_H}{b_L} \right)^{\frac{1}{\beta}} \left( 1 + \left( \frac{n_H}{n_L} \right)^{\frac{-1}{\gamma}} \left( 1 + \frac{n_H}{n_L} \right) \left( \frac{a_E}{a_I} \right)^{\frac{1}{\gamma}} \right)^{\frac{1-\alpha\beta}{\alpha\beta}} \quad (19)$$

This relationship can be labelled the Research and Development Arbitrage curve or *RDA*-curve as it traces out the combinations of relative wages and  $n_H/n_L$  for which the R&D sector has no incentive to reallocate resources and both goods ranges grow at the same rate. Relative wages enter this relation through relative profits, which affect the relative value of innovations. This in turn changes the optimal allocation of available R&D resources over Entrepreneurial and Incumbent Firms' R&D. The relative range,  $n_H/n_L$ , also enters through profits but in addition the knowledge spillovers assumed in the innovation function. Figure 2 shows the *RDA*-curve, which is convex downward sloping over the entire domain (see Appendix). The intuition is that at larger  $n_H/n_L$  it is ceteris paribus more attractive to invest R&D resources in expanding  $n_L$  because of larger intratemporal knowledge spillovers. To offset this tendency and be in equilibrium a lower relative wage is required.

The arrows indicate the direction in which  $n_H/n_L$  will change when one starts in a point off the *RDA*-curve. Below the *RDA*-curve  $n_H/n_L$  will grow. The intuition is once more quite straightforward. In that situation relative wages are, given the available knowledge stocks, too low. Consequently relative profits are too high and this provokes too much entrepreneurial activity, causing  $n_H/n_L$  to rise.<sup>8</sup> Hence the equilibrium is only stable if the *RDA*-curve intersects the *PMA*-curve from above as has been verified more formally in the Appendix.

[Figure 2 about here]

Combining Figures 1 and 2 yields the complete model in Figure 3.

[Figure 3 about here]

Starting from a point such as *A* in the right panel, the corresponding position on the *PMA* relative to the *RDA*-curve determines that  $n_H/n_L$  will grow. As  $n_H/n_L$  increases, the relative labour demand curve in the right panel shifts out and relative wages increase. In the left

panel the economy moves up along the *PMA*-curve. This process stops and the model is in steady state equilibrium when the intersection of *PMA* and *RDA* is reached at points *B*.

### PREDICTIONS AND HYPOTHESES

Now consider how the model responds to the introduction of a new GPT. As was argued above a new GPT opens up new opportunities for entrepreneurs to develop new products and processes. The best way to introduce such a shock in the model is to analyse the impact of a sudden increase in the productivity of R&D workers in generating new ideas. In terms of the model we should therefore consider an increase in  $a_R$ . It can easily be verified in equation (10) that the *PMA* will not shift. Instead equation (19) shows that the *RDA* shifts out. This puts the old equilibrium below the new *RDA*-curve and  $n_H/n_L$  will start to rise. This pushes relative wages up along the *PMA*-curve. When the GPT is fully absorbed the initial shift in  $a_R$  will be reversed and with a lag  $n_H/n_L$  and relative wages will come down again. But for our purpose we should analyse what happens to per capita income and entrepreneurial activity over this cycle. From equation (16) we can derive the impact on the allocation of R&D resources. The initial upward shift in  $a_R$  obviously causes an increase in entrepreneurial R&D. Then the rise in  $n_H/n_L$  and in relative wages moves the allocation in the opposite direction.

The model allows for the exact measurement of economic growth in terms of utility. In the data, however, one must realise that new products enter with a lag. In addition they frequently face price reductions and quality increases in the early stages of the product life cycle. This implies that the contribution of new goods in economic growth is underestimated in the data on production value and price indexes. Real GDP therefore underestimates the impact of Entrepreneurial R&D. The effects of Incumbent Firms' R&D on the other hand is accounted for more adequately as cost reductions reduce the price index and thereby show up in real GDP. We expect a drop in measured productivity growth at given aggregate R&D levels when entrepreneurial activity increases. Measured productivity should pick up once the R&D is reallocated towards Incumbent Firms' R&D and measurements are adjusted to the changes in the consumption bundle. Hence we can formulate Hypothesis 1:

*The relationship between entrepreneurial activity and measured economic growth is negative but turns positive with a lag following the introduction of a new GPT.*

### DATA AND ANALYSIS

To analyse the dynamic relationship between entrepreneurial activity and GDP we use the COMPENDIA-data set that includes 23 OECD countries and contains information on entrepreneurial activity, measured as the bi-annual ratio of non-agricultural business owners to the total labour force, and GDP for the period 1972-2002.<sup>9</sup>

*Identifying the cycles*

First consider the relationship between GDP/Cap-growth and Entrepreneurial activity. Figures 4-7 present this relationship over time for the United States, Germany, Japan and the United Kingdom. A 4<sup>th</sup> order polynomial has been fitted to eliminate the many other external factors that affect the GDP/Cap growth rate over time.

[Figure 4-7 about here]

In the four selected countries the cycles in Entrepreneurial activity and GDP/Cap growth are clearly visible. It should also be noted that these cycles seem to be out of phase by as much as 10 years. Especially in the United States, arguably the technology leader in the world, the lag is long and the sustained rise in entrepreneurial activity since the mid-seventies yields growth at a lag of more than 10 years. In Germany, a less entrepreneurial economy by all measures, the level of entrepreneurial activity only starts to pick up in the mid-eighties but growth follows in the early nineties. In the UK we observe two cycles in GDP/Cap growth for 1 full cycle in Entrepreneurship. Japan, with its sustained recession in the nineties, sees the effects of a continued fall in Entrepreneurship since the early seventies. Growth in GDP/Cap, however, only starts falling in the early eighties, a lag of about 10 years.

### **Identifying technological leaders and followers**

Countries go through the various stages of the cycles identified above at different points in time. Following the introduction of a GPT, technological leaders will go through the early phase of more entrepreneurial activity at earlier points in time than followers do. To identify which countries are leaders and which are followers we analyse the development over time (period 1972-2002) of our entrepreneurial activity measure, the business ownership rate, for the 23 countries in our data set.

As described earlier business ownership rates fell in most of the 20<sup>th</sup> century. However, following the ICT revolution and increasing uncertainty from the 1970s onwards, business ownership rates increased in several countries. Those countries that experienced this shift earlier in time may be labeled technological leaders while those experiencing this shift at a later point in time may be labeled technological followers. However, in trying to identify leaders and followers also the *levels* of business ownership should be taken into account. Carree et al. (2002) found that countries with very high business ownership rates experience a growth penalty in the form of growth foregone. This is probably because there are too many marginal entrepreneurs who could be more productive for the economy if they would work as a wage-earner in a bigger firm. Too high business ownership rates may also point at a lack of R&D investments. This implies that it is not likely that a country with a high level of business ownership experiencing even further increases in business ownership rates is a technological leader. Also, a certain minimum economic development level is probably required in order for the labor force to produce sufficient numbers of entrepreneurs that are able to generate innovative activity.

Combining formal quantitative analysis (regressions of entrepreneurial activity on a constant, time and time squared), and qualitative assessment of the data (taking into account the level of GDP per capita and the level of business ownership), we may identify four groups of countries, ranked by the extent to which they may be labeled leaders or followers:<sup>10</sup>

#### 1. United States

Our data confirm that the United States is the technology leader in the world. It is the country where the rise in business ownership rate came earliest, from the early 1970s onwards. Also, our regression analysis reveals a downward pattern again from 1991 onwards. This may reflect that entrepreneurial activity declines in the later phase of the cycle following the introduction of a new GPT, as described above.

#### 2. Ireland, Switzerland and Canada

The development over time of the business ownership rate suggests that these three countries are the closest followers of the United States. Like the US they have an upward pattern of business ownership since the 1970s. However, the difference is that the later phase of the cycle (levelling off of the rise) is reached only recently, around the year 2000. Hence these countries have reached the later phase at a later point in time compared to the US. Also, in the early 1970s GDP per capita levels were far behind the US, especially for Ireland which was clearly not a leader in those times. In other words the rise for Ireland in the 1970s and 1980s is probably to a certain extent a 'catch-up' effect and hence of a different nature than the rise in business ownership in the US.

#### 3. Austria, Belgium, Denmark, Finland, Germany, Netherlands, Sweden, United Kingdom, Iceland, New Zealand

These countries reached the bottom of the U-shaped relation in the mid-1980s. Hence the rise in business ownership came later than for the countries in the first two groups.

#### 4. France, Luxembourg, Norway, Japan

These countries have an ever decreasing business ownership rate over the whole period of the data set, until 2002. The phenomenon of more entrepreneurial activity following the introduction of a GPT cannot be detected for these countries.<sup>11</sup>

5. A final group of countries does not seem to fit in this analysis. The development of business ownership is too different from the other countries. For Portugal and Spain the business ownership rate is more or less constant over the whole period. Three other countries (Greece, Italy, Australia) have an increasing business ownership rate. However, the rise is combined with a high *level* of business ownership which makes them uncomparable with the countries in group 2. Moreover, it may reflect that there are too many marginal entrepreneurs in these three countries.

## DISCUSSION

Various authors have identified a reversal of the downward trend in business ownership rates in modern economies since the 1970s, implying a U-shaped relation between entrepreneurial activity and economic development (e.g. Carree et al., 2002). In this paper we develop a model that explains the U-shaped relationship in a formal way as the result of a technology regime shift that is brought about by the introduction of a new GPT. The theoretical model is illustrated with some empirical exercises making use of the COMPENDIA data base which contains data on business ownership rates and per capita income for 23 OECD countries from 1972 onwards.

The empirical exercises seem to identify considerable lags between increased entrepreneurial activity and economic growth, suggesting that the exploration activities performed by the entrepreneurs results in economic growth only at later phases of the product life cycle when the new products are exploited and developed further in incumbent firms. Also, by analysing the development over time of the business ownership rates we identified four groups of countries, in terms of the extent to which the countries might be labeled as leaders or followers. Not surprisingly, the United States came out as the technology leader of the world.

Our empirical work has several limitations. *First*, we use the business ownership rate as measure of entrepreneurial activity. The business ownership rate contains many shopkeepers or 'mom-and-pop' businesses. Innovative entrepreneurs are only a small fraction of the business owners (Wennekers and Thurik, 1999). Both high-tech and low-tech firms are treated as the same. It is likely that the high business ownership rates in, for instance, Greece and Italy reflect many 'marginal' entrepreneurs, and hence they do not fit in the theoretical model developed in this paper. *Second*, and related to the first limitation, we do not make a distinction between sectors, the cycles may be more clearly visible for high-tech economic activity compared to low-tech economic activity. *Third*, several non-technology related reasons may account for developments in business ownership as well. For instance, in the United Kingdom government policy has been directed toward small firms while in France policy was focused on large firms for a long time. This certainly explains some of the upward trend in the UK in the 1980s and the downward trend in France. *Fourth*, and perhaps most important, efforts allocated to R&D activity play a vital role in our theoretical model. However, our empirical exercises do not take account of the differences that exist between countries in the relative amount of R&D investments.

For all the above reasons our empirical results should be regarded as exploratory. Our exercises are meant to give the reader some clue as how these cycles may come about in practise. However, to gain more insight in these processes we should build more sophisticated empirical models incorporating R&D levels and formally assessing the lags involved in the relationship. Also, to identify leaders and followers, more detailed information should be taken into account. This is the subject of future empirical research.

Once these type of exercises are performed, important policy conclusions may be drawn. For instance, if it would be obvious that Europe is about to move to a later phase in the technology life cycle, then we may conclude that the stimulation of entrepreneurial activity seems a good idea in Europe if implemented swiftly but might actually be wasteful if the current Schumpeter Mark I technology regime ends quickly. Similarly for the US we may then conclude that current levels of entrepreneurial activity need not be stimulated, especially if a regime switch is imminent. However, as indicated, more empirical work is required to be able to draw this type of conclusions.

## Endnotes

<sup>1</sup> The structure is closest to that presented in Grossman and Helpman (1991b) chapter 4.

<sup>2</sup> It is concave because demand is convexly downward sloping in the relative wage. Hence an ever-larger increase in  $n_H/n_L$  is required to push relative demand out and relative wages up by the same percentage.

<sup>3</sup> Note that the short-run elasticity of substitution between high and low skilled labour can be derived and is strictly negative. Its absolute value is given by,  $\sigma_{SR} \equiv 1/(1-\alpha\beta)$ .

<sup>4</sup> The usual way of thinking about innovation in these models is to assume perfect patent protection. The patent then yields a return in the form of future profit flows and the R&D investment required can be financed by selling such assets. One could also think of an entrepreneur who needs to finance the initiation of a new firm. In that case R&D can be interpreted as non-production labour required for starting up a firm and finding a niche in the market. To finance such up-front investments the entrepreneur must sell his future profits as assets, yielding at least  $r$  in equilibrium for consumers to be willing to finance investment.

<sup>5</sup> The mathematics are much more complicated and little insight is gained by requiring the R&D sector to compete for high skilled labour with production. It would allow for an interpretation of Research as truly entrepreneurial activity as that generally requires skills. See Sanders (2004) for a digression in that direction.

<sup>6</sup> See Jones (1995, 2005) for an elaboration of the role of knowledge spillovers in endogenous growth theory. The proportional specification was chosen for convenience and empirical support is weak. Jaffe and Caballero (1993) for example suggest that the assumed constant returns to accumulated knowledge may be too optimistic and depreciation rates of knowledge, in particular in the 80s, may be high. A more general spillover structure was analysed in Sanders (2004).

<sup>7</sup> Note that the fact that profits grow at the same (negative) rate in both ranges in the steady state was used to eliminate the ratio of discount rates from the ratio of patent values.

<sup>8</sup> Krugman (1998) uses and refers to this intuitive type of dynamics analysis as ad-hoc dynamics. Proofs and derivations are left for the Appendix.

<sup>9</sup> See for details Van Stel (2005).

<sup>10</sup> Details of this analysis are available on request by the authors. The current empirical analysis should be marked as preliminary.

<sup>11</sup> This is not to say that these countries are technological laggards as institutions may hamper entrepreneurial activity in these countries.

## **ABSTRACT**

Serial entrepreneurs are business owner-operators who commence, operate and dispose of a number of business ventures. This paper draws on data from 199 micro firms in New South Wales, Australia to explore the background and characteristics of a cohort of serial entrepreneurs, identify some aspects of their current operations, and assess whether the businesses of these serial entrepreneurs are more likely to grow than other entrepreneurial ventures.

The results indicate that serial entrepreneurs tend to be male, relatively well educated, aged between 30-49, and Australian-born. Many (just under half) come from a family with a prior background in business ownership. A third of them concurrently operate another business, and a majority has a strong growth orientation.

Analysis of data between serial and other entrepreneurs reveal some statistically significant differences between the two cohorts. Compared to other entrepreneurs, serial entrepreneurs are more likely to concurrently operate another business; less likely to operate their current venture as a home-based enterprise; and more likely to want to expand their business in future. Serial entrepreneurs, when compared to other entrepreneurs, also tend to be slightly older, are more likely to be male, and are more inclined to buy a business as a going concern.

## INTRODUCTION

Many studies of entrepreneurship examine the business venture, or the entrepreneurial individual, at a particular point and often overlook the fact that, for many people, entrepreneurship may as much be an on-going way of life as it is a particular business project. For these individuals, enterprising activity may mean undertaking several different projects over the course of a working life. The end result is the creation, expansion and termination of a series of different business ventures over many years.

In recent years, this notion of so-called “habitual,” “serial” or “continual” entrepreneurship has begun to be explored in some detail within the academic community. However, the body of knowledge about such operators is still limited. Much more remains to be known about serial entrepreneurs. What are the particular personal characteristics and demographic features of such businesspeople? How do they operate their businesses? And do they differ in any substantive way from other entrepreneurs?

The purpose of this paper is to attempt to shed some further light on serial entrepreneurs. It examines some recent evidence concerning the personal background and business operating features of such business owners, and compares them to other entrepreneurs, drawing on data from a recent large-scale survey of micro-enterprises in New South Wales, Australia.

## LITERATURE REVIEW

The notion that some entrepreneurs may engage in multiple business ventures, either simultaneously or sequentially, has been explicitly recognised by a number of researchers. Early contributors to the field included MacMillan (1986) and Donckels, Dupont & Michel (1987). However, despite MacMillan’s (1986) challenge to learn more about habitual entrepreneurs, Wright, Westhead and Sohl (1998) argue that little had been achieved prior to 1998. A search of the literature since that time also reveals only a small handful of new research contributions.

A first issue to be dealt with in this field is semantic: what exactly is a serial, habitual, repeat or continuous entrepreneur? All of these terms have been employed at one stage or another, yet different authors have occasionally ascribed different interpretations to each of them. For example, Hall (1995) developed a dichotomous classification of definitions, which were further refined by Kolvereid and Bullvag (1993), Westhead and Wright (1998), and later by Westhead, Ucbasaran, and Wright (2003). Included in these definitional discussions is the related concept of the portfolio entrepreneur (Hall 1995). This refers to an individual who concurrently operates two or more enterprises (Westhead *et al.*, 2003). The differentiating characteristic between serial and portfolio entrepreneurs is the timing of business ownership, namely whether two or more businesses are operated at the same time. The serial entrepreneur only ever operates one business after another, whilst the portfolio entrepreneur owns multiple businesses at the same time. Not surprisingly, the two categories frequently overlap (Hall 1995).

Whilst the terms are sometimes said to be quite different, the phrases “habitual” and “serial” entrepreneur are also frequently used as interchangeable terms, and can be regarded most simply as an individual who starts one enterprise and then later begins another (Wickham 2004). For the purpose of this paper we focus on serial entrepreneurs as individuals who currently own and operate a business and who have previously owned another enterprise. We also discuss the number of serial entrepreneurs who may also be portfolio entrepreneurs.

Serial entrepreneurs are frequently juxtaposed against novice entrepreneurs. The latter category represents most entrepreneurs and includes current business owners who have no prior experience in creating or owning a business venture (Westhead *et al.*, 2003).

Most research into this phenomenon to date has employed a qualitative case research methodology (eg Rosa, 1998) with limited quantitative analysis (eg Alsos and Kolvereid, 1998). This makes it difficult to generate valid, generalisable findings. Even when quantitative methodologies have been employed, the data and subsequent analysis has frequently been highly aggregated such that detailed information about serial entrepreneurs has been difficult to ascertain (Wright *et al.*, 1998). However, some entrepreneurial demographics appear to have emerged, although the findings are sometimes contradictory. Birley and Westhead (1993) found that the proportion of habitual entrepreneurs to total entrepreneurs tended to be quite small, ranging from 12% to 36%. In contrast, Schollhammer (1991) in a US study found that 51% of entrepreneurs had two or more ventures. Most habitual entrepreneurs appear to be men, and they tend to have higher educational qualifications than novice entrepreneurs (Kolvereid and Bullvag, 1993; Westhead and Wright, 1998).

At the same time, many characteristics of habitual entrepreneurs appear to be either highly heterogeneous or quite variable. It appears that they do not always tend to remain in the same industry (Wright, Robbie, and Ennew, 1997), and that their motivations, the type of venture they operate, and the way they manage may in fact vary significantly between their first and subsequent ventures (Wright, Westhead & Sohl, 1998).

Environmental considerations and contextual frameworks, such as enterprise location and stage of the business life cycle, are some issues that seem to have an impact on serial entrepreneurship (Wright, Westhead and Sohl, 1998). The motivations for habitual entrepreneurship can be quite diverse, and include a desire for independence, monetary security, the belief that it ‘adds to the excitement of life’ (Westhead and Wright, 1998), a sense of duty, and the desire to contribute to local communities (Mankelov and Merrilees, 2001; Rosa, 1998).

Serial entrepreneurs conceivably also have some skills and resources that other, novice entrepreneurs will not. It might reasonably be supposed that they will have gained greater experience in launching and operating a business, and thus overcome many of the “learning curve” problems typically experienced by first-time business venturers. However, this does not always appear to be the case: neither Kolvereid nor Bullvag (1993) or Birley and Westhead (1993) could find any evidence to support this contention. On the other hand, there is some evidence to suggest that serial

entrepreneurs are able to better access sources of funding for their next start-up, arguably because of a 'better track record' (Alsos and Kolvereid, 1999; Westhead and Wright, 1998).

Wright *et al.* (1998) identified a number of areas in which future research into habitual entrepreneurship was seen as desirable. These included the background characteristics of the entrepreneur, their management practices, and their behaviour within specific segments of the business population. Identifying the characteristics, firm behaviour and growth orientation of habitual entrepreneurs is also an important issue for policy makers (Westhead *et al.*, 2003). Such research may help in determining if serial business ownership is a reliable indicator of future business performance, and whether or not specific programs should be targeted towards this entrepreneurial subset.

While concern with, and understanding of, this group of individuals is growing; the phenomenon of serial entrepreneurship appears to have received only minor analysis so far amongst one part of the business population: the microfirm sector. Microfirms represent the majority of firms operating in most nations today, yet their role and impact is often overlooked or poorly understood. Traditionally they have been treated as a phenomenon with limited relevance to the wider economy, even though they are in fact a major structural force in almost all societies. In Australia, for example, a business enterprise is deemed to be a micro-firm if it has less than five employees (Australian Bureau of Statistics, 2002). In June 2001, there were an estimated 1.1 million small and medium-sized business enterprises (SMEs) in the country, of which 80% were regarded as micro-sized (Australian Bureau of Statistics, 2002).

## METHODOLOGY

Information on respondents was collected during 2003, as part of a study examining the structure and operating practices of employing micro-businesses within the state of New South Wales (NSW), Australia. The study was undertaken by the NSW Department of State and Regional Development, and was based on a survey instrument employed in a prior study of micro-businesses undertaken by the Canadian Government in 2000 (Industry Canada, 2001; Papadaki and Chami, 2002). The NSW survey was restricted to the population of employing firms who had been in existence for at least four years, and stratified to account for proportionate variations in population distribution between regional and metropolitan areas, as well as differences between the goods and services sectors of the economy. The survey was limited to the owner-operators of firms, and conducted through a telephone interview.

The data was collected as part of a larger study into established micro-firms that imposes some potential limitations on the generalisability of the results. For example, the findings cannot be regarded as representing all small enterprises, since they specifically relate to micro-firms; there is also a survivorship bias in that only firms that have existed for four or more years were included. Caution is therefore essential in interpreting the results. Despite these limitations, the results do provide some important understandings of serial entrepreneurs and how they differ from other owner-operators.

As discussed in the preceding literature review, there are a number of ways in which to define a “habitual entrepreneur.” For the current study, a simple and easily operationalised definition was employed, in which a serial entrepreneur was taken to be any person who currently owns and operates a business, and who has previously owned and managed another enterprise.

For the data set examined in this paper, a total of 753 responses were available, of which 199 respondents (26%) indicated that they had previously owned and operated a business before their current venture. The proportion of total respondents who fell into the serial entrepreneur category supports the earlier arguments of both Birley and Westhead (1993) and Alsos and Kolvereid (1998) that serial business venturers exist in substantial numbers amongst the general business community.

## **RESULTS**

In any exploratory analysis of entrepreneurship in applied situations, two sets of factors are often equally important: the personal characteristics and background of the entrepreneurial individual, and the characteristics of the firms that they own. Both aspects were examined in this study. This section starts with a descriptive summary and is followed by a comparison of results between serial and novice entrepreneurs. These comparisons are intended to give an insight into questions such as: Are serial entrepreneurs, and the firms that they operate, different from those run by other entrepreneurs? Are the activities of serial entrepreneurs merely an interesting sideshow, or can it be inferred that there are substantive differences that set them apart from other owner/operators? As most of the data was collected using categorical responses, a Chi-squared test for independence was used to compare groups.

### **Background Characteristics**

As a group, serial entrepreneurs in the survey tend to be male, well educated, aged between 30-49, locally born (Australian), and slightly less likely to have come from a family background of business ownership. More detailed results are included in Table 1, which also forms the basis of comparisons with non-serial entrepreneurs that are presented later in the paper.

-----  
Insert Table 1 about here  
-----

Overall, firms owned by serial entrepreneurs in the survey tend to have been started from scratch, be family owned, have operated for over ten years, are run as independent firms (that is, they tend not to be franchises), and are based in premises separate to the entrepreneur’s residence. Only a minority continues to concurrently operate another business. They tend to have experienced positive sales growth (but not growth in employee numbers) and express a likelihood that they will expand in the short term. As was the case for personal characteristics, more detailed results are included in Table 2, which also forms the basis of comparisons with non-serial entrepreneurs that are presented later in the paper.

### **Differences In Characteristics**

Table 1 identifies differences in personal characteristics between serial entrepreneurs and other entrepreneurs. From this perspective there are statistically significant differences (at  $p \leq 0.05$ ) between serial entrepreneurs and other entrepreneurs in respect of gender distribution (with serial entrepreneurs more likely to be male than the overall respondent cohort), and age (continuous entrepreneurs tended to be slightly older than other respondents). In contrast, no significant differences could be found between the two groups on the grounds of educational attainment, country of origin, or early family business involvement.

The fact that serial entrepreneurs tend to be slightly older than other respondents should not be surprising; as Westhead and Wright (1998) and Wright *et al.* (1998) have suggested, prior business experience is accumulated over time, producing a cohort that is usually older than novice entrepreneurs. The relatively low proportion of female habitual entrepreneurs supports the earlier suggestion of Kolvereid and Bullvag (1993) that most serial venturers are males. However, the current findings do conflict with their suggestion that serial entrepreneurs are more likely to have obtained higher educational qualifications than other entrepreneurs; no such difference could be found in this study.

Table 2 identifies differences in business characteristics between businesses owned by serial entrepreneurs and other entrepreneurs. From this business perspective there are statistically significant differences (at  $p \leq 0.05$ ) associated with five characteristics. Compared to other respondents, serial entrepreneurs are: more likely to buy a going concern than other entrepreneurs; less likely to operate their current venture as a home-based enterprise; more likely to concurrently operate another business; more likely to have higher levels of sales growth; and more likely to want to expand their business in future. No significant differences are evident in respect of the family business ownership, duration (years of operation) of the current business venture, franchise operation, or employee growth. While not reflected in the tables, serial entrepreneurs were also asked why they left their previous business. Interestingly only 33 indicated a profitable sale while 23 indicated a lack of profitability. Another 67 cited other reasons that were not available.

These results lend support to the arguments of Wickham (2004), who suggests that the prior experience of serial entrepreneurs means they are likely to operate their business in a somewhat different manner to novice entrepreneurs. They are more likely to engage in portfolio entrepreneurship as a means of spreading or diluting their business risks, and are more comfortable with the notion of operating simultaneous enterprises than are novices. In addition, prior commercial success may provide them with greater financial assets (accumulated capital and access to lenders), which gives them a greater opportunity to buy a going concern than is possible for other business venturers. Their high growth orientation may also reflect a different set of priorities and motivating factors to those of novice entrepreneurs (Wright *et al.*, 1998).

## CONCLUSION

This paper has presented some descriptive statistics and exploratory analysis about serial entrepreneurship within the employing micro-firm sector, a group that has not previously been extensively examined. It has confirmed that, for this cohort, the unique differences in personal characteristics and business attributes associated with habitual entrepreneurs do indeed exist. Serial entrepreneurs in the micro-firm sector are more likely to concurrently own another business, more likely to have higher sales growth and be more inclined to expand than other owner-managers. These latter differences compared to the non-serial business cohort suggest that there may be a policy advantage in focusing on serial entrepreneurs as a group more likely to generate greater economic growth and wealth than novice venturers.

Although this paper has identified some important characteristics about serial entrepreneurs, much more still remains to be revealed. For example, why are serial entrepreneurs motivated to start a second or subsequent business? And why do they exit a venture? Does exit reflect a desire to start another business because of 'boredom' with the existing business or a need to experience the thrill of starting another business? Does the overlap with portfolio entrepreneurs suggest preplanning of habitual activities? Alternatively, do serial entrepreneurs exit because they lack the managerial skills to grow a business? Is there a particular point in the business lifecycle at which they are more inclined to exit? These, and many other issues relating to serial entrepreneurship, need to be investigated in more detail by the research community, and may help build a much more complete picture of this sector.

## **ABSTRACT**

Three recognized job satisfaction models (situational, dispositional, and interactional) are used to examine the job satisfaction of executives in small businesses. Based on a cross-sectional sample of 65 male executives, the three job satisfaction models are compared. Among the three job satisfaction models, the interactional model accounted for the most unique job satisfaction variance followed by the situational model and, lastly, the dispositional model.

## **INTRODUCTION**

Studies have shown that entrepreneurs (Cooper & Artz, 1995), executives (Judge Boudreau, & Bretz, 1994), and self-employed (Blanchflower and Oswald, 1998, Bradley & Roberts, 2004, Hundley, 2001, and Naughton, 1987) are very satisfied with their job/work. What is not clear from the literature is how and why executives of small businesses are satisfied.

There are two predominate reasons why these studies do not explain how and why small business executives are satisfied. First, the studies have not tested job satisfaction models per se. Cooper and Artz (1995) found results that contradicted the theoretical model (discrepancy theory) they used as a framework for their study. Despite a well executed study of executives by Judge and associates (1994), these researchers did not use recognized job satisfaction models in their study. Second, the studies used less than appropriate samples or data collections in explaining how and why small business executives are satisfied. Judge and associates used subjects identified from the fifth largest national executive search firm in the United States. Most, if not all, studies addressing self-employed individuals' job satisfaction have been based on secondary data, e.g., Naughton (1987) and Hundley (2001) used data from the 1977 Quality of Employment Survey for their studies; Blanchflower and Oswald (1998) used the National Child Development Study; and Bradley and Roberts (2004) used the National Survey of Families and Households. Studying entrepreneurs, Cooper and Artz (1995) used data from a data set collected by the National Federation of Independent Businesses. The use of secondary data limit the opportunity to test recognized job satisfaction models as these studies only examined individual variables of job satisfaction, e.g., autonomy (Hundley, 2001; Naughton, 1987), not job satisfaction models. As this shows, little, if anything, is known about how and why executives of small businesses are satisfied. This is despite the job satisfaction literature has established three models that have successfully accounted for job satisfaction. These are the situational,

dispositional, and interactional models. The three models have been used extensively to predict the job satisfaction of employed individuals in organizations. Due to the variety of samples used in the literature, some may assume that these job satisfaction models apply to small business executives. This, however, has not been empirically tested. Thus, the purpose of this study is to account for job satisfaction of executives of small businesses using the situational, dispositional, and interactional job satisfaction models.

## **LITERATURE REVIEW AND HYPOTHESES**

### **The Situational Model**

The situational model suggests that job satisfaction is derived from the job characteristics. This approach is based on the implicit assumption that all persons have similar needs and are, therefore, satisfied by the same job characteristics. The most recognized situational model is the Job Characteristics Model (JCM; Hackman & Oldham, 1980). Even though the JCM includes individual differences (*growth need strength*) in association with the job characteristics, it has for the most part been used as a content model where job dimensions are correlated directly with job satisfaction (Loher, Noe, Moeller, & Fitzgerald, 1985; Fried & Ferris, 1987). Thus,

*H1: Task variety will be positively associated with job satisfaction.*

*H2: Autonomy will be positively associated with job satisfaction.*

*H3: Task identity will be positively associated with job satisfaction.*

*H4: Feedback will be positively associated with job satisfaction.*

### **The Dispositional Model**

The dispositional job satisfaction model argues that certain relatively stable characteristics of a person influence job satisfaction independently of the job characteristics and situation (Judge, Heller, & Mount, 2002). In 1976, Locke suggested that the dispositional approach may be useful in explaining job satisfaction and, since then, the dispositional model has made important contributions to the OB literature (House, Shane, & Harold, 1996). Many of these contributions have been made using the five personality factors (Big Five, Goldberg, 1990) as a framework representing the dispositional approach.

The Big Five provides a useful taxonomy for the personality (dispositional) construct (Ozer & Reise, 1994) and has been generalized across measures, cultures, and sources of ratings (Barrick & Mount, 1991). Despite the Big Five provides a useful personality model, dispositional job satisfaction research has focused on isolated personality factors of the Big Five, e.g., neuroticism. This practice continues even that the use of individual personality factors does not provide an appropriate dispositional model, or as pointed out by Shaver and Scott, “*don’t send a scale to do an inventory’s job*” (1991: 32). As the Big Five provides a more comprehensive taxonomy of personality, using all five personality factors as a dispositional model improves conclusion validity relative to the practice of focusing on one or two *a priori* selected personality factors. In spite of these positive aspects of the Big Five as a personality model, it has received limited attention in job satisfaction literature (Judge et al, 2002). Thus, it is deemed appropriate

to examine all five personality factors of the Big Five in this study. Further, in accordance with the meta-analytic findings of Judge and associates (2002), it is hypothesized that

*H5: Neuroticism will be negatively associated with job satisfaction.*

*H6: Extraversion will be positively associated with job satisfaction.*

*H7: Openness to experience will be negatively associated with job satisfaction.*

*H8: Agreeableness will be positively associated with job satisfaction.*

*H9: Conscientiousness will be positively associated with job satisfaction.*

### **The Interactional Model**

The interactional model states that the fit between the person and environment influences job satisfaction (Chatman 1989). This approach is known as the Person-Environment Fit (P-E Fit) model. Spokane (1985) reviewed the P-E Fit literature and concluded that the P-E Fit is positively related to job satisfaction. Also, in their empirical meta-analysis, Assouline and Meir (1987) found support for a positive relation between P-E Fit and job satisfaction. Thus,

*H10: P-E Fit will be positively associated with job satisfaction.*

## **METHODOLOGY**

A survey instrument was administered to 406 executives of small companies selected from the Rocky Mountain High Technology Directory using a two-contact procedure (Salant & Dillman, 1994) yielding gross response rate of 21 percent. Seven surveys from female respondents and three surveys from non-Caucasian respondents were eliminated due to the potential for generating background noise. Additionally, two surveys were eliminated – one with minus 400 percent in sales growth and one with 700 employees. The later was eliminated to focus on small firms with 350 or less employees. This reduced the sample to 65 usable surveys from male executives. A test for non-response bias showed no significant differences at the .05 level between respondents and non-respondents.

### **Measures**

Job satisfaction, the dependent variable, was measured using the Minnesota Satisfaction Questionnaire (MSQ; Weiss, Dawis, England, & Lofquist 1967). The MSQ was modified by eliminating three items that address satisfaction with supervisors since the subjects typically do not have a supervisor in the traditional understanding. The reliability coefficient for the modified MSQ used in the present study was 0.91.

The four job characteristics variables were measured using the Job Characteristics Inventory (JCI; Sims, Szilagyi, & Keller, 1976). The JCI was used because it has been recommended for use with MSQ (Pierce, McTravish, & Knudsen, 1986), it mirrors the job characteristics-construct (Pierce et al., 1986), it has been found to be psychometrically better than Hackman and Oldham's (1975) Job Diagnostic Survey (Aldag, Barr, & Brief, 1981; Pierce & Dunham, 1978),

it has four to six items per job dimension which is necessary to achieve adequate validity (Idaszak, Bottom, & Drasgow, 1988), and it does not have any reversed-scored items introducing additional variance (Harvey, Billings & Nilan, 1985; Idaszak & Drasgow, 1987). Further, the coefficient alpha reliability estimate for the JCI has been referred to as “sufficiently high for research purposes” (Fried, 1991: 691). In this study, the reliability coefficient for the JCI was 0.81.

The five personality variables were measured using the NEO-Five Factor Inventory Form S (NEO-FFI; Costa & McCrae, 1991). Validity for the five factors of the NEO-FFI has been examined across a large number of studies providing strong evidence of convergent and discriminant validity (McCrae & Costa, 1987; Costa & McCrae, 1991).

The person-environment fit (P-E Fit) variable was measured using lack of stress as a proxy. The use of lack of stress as a proxy for P-E Fit was chosen based on this quote: “*stress is defined as a lack of person-environment fit*” (Eulberg, Weekley, & Bhagat, 1988: 337). These researchers also pointed out that lack of P-E Fit can be identified only by an individual’s experience of stress. Stress was measured using a 16-item measure, which has been used in another study of executives’ job satisfaction (Judge et al., 1994). Judge and colleagues (1994) reported that the stress measure had a reliability estimate of 0.84; in the present study, it was 0.87.

The control variables included age, education, job tenure, firm size (number of employees), and firm performance (sales growth).

## Data Analysis

Ordinary least squares hierarchical regression analyses were used to test the hypotheses. These were performed in two steps with the control variables entered first and the independent variables second making it possible to determine the amount of unique variance accounted for by each of the three models. By calculating the change in the adjusted coefficient of determination (adjusted  $\Delta R^2$ ), it was possible to compare the amount of unique variance accounted for by each model as the number of independent variables included in the regression equation and the sample size were taken into account in the adjusted coefficient of determination (Hair, Anderson, Tatham, & Black, 1998).

## RESULTS

Table 1 shows the means, standard deviations, and correlations for the variables used in models. The mean for the job satisfaction measure was 3.94 which suggest that the respondents were *very satisfied* with their jobs. All independent variables, except for openness to experience and agreeableness, were positively correlated with job satisfaction at the 0.05 level.

[Table 1 about Here]

Table 2 presents the regression results. Model 1 displays the regression results for the control variables only. The adjusted  $R^2$  for the control variables (model 1) was 0.190 ( $F = 3.996^{**}$ ). The results for situational, dispositional, and interactional approaches are shown in models 2-4, respectively. The situational variables (model 2) explained 19 percent of unique variance (adjusted  $\Delta R^2 = 0.192$ ,  $F = 5.381^{***}$ ). Hypotheses 1 (task variety), 2 (autonomy), and 4

(feedback) were supported at the 0.10-level of significance. The dispositional variables (model 3) accounted for 14 percent of unique variance (adjusted  $\Delta R^2 = 0.139$ ,  $F = 4.132^{***}$ ). Hypotheses 5 (neuroticism), 6 (extraversion), and 9 (conscientiousness) were supported at the 0.10-level of significance. The interactional variable (model 4) accounted for 17 percent unique variance (adjusted  $\Delta R^2 = 0.166$ ,  $F = 6.876^{***}$ ). Model 4 shows that hypothesis 10 (P-E Fit) was supported.

[Table 2 about Here]

Additional regression analyses were performed where the not-significant variables were eliminated from consideration. The regression results for a model that considered task variety, autonomy, and feedback showed similar support for hypotheses 1, 2, and 4 as model 2 (Table 2) and had a marginally improved fit with the data (adjusted  $\Delta R^2 = 0.189$ ,  $F = 5.873^{***}$ ). The regression results for a model that considered neuroticism, extraversion, and conscientiousness showed similar support for hypotheses 5, 6, and 9 as model 3 (Table 2). This model accounted for more job satisfaction variance and had better fit with the data (adjusted  $\Delta R^2 = 0.162$ ,  $F = 5.344^{***}$ ) than model 3 (Table 2).

## DISCUSSION

The results of the present study show that the interactional model predicts job satisfaction best among the three individual job satisfaction models as it accounted for 17 percent of job satisfaction variance (adjusted  $\Delta R^2 = 0.166$ ,  $F = 6.879^{***}$ ). Even that the situational model accounted for more job satisfaction than the interactional model, it did not fit the data as well as the interactional model as shown by the F-scores for models 2 and 4 (Table 2). The dispositional model accounts for less job satisfaction variance and fits the data less well than either of the two other job satisfaction models. This was also the case when the not-significant dispositional variables were excluded from consideration.

The results of the present study were compared with meta-analyses on the job characteristics (Behson, Eddy, & Lorenzet, 2000; Fried & Ferris, 1987), and the Big Five (Judge et al., 2002); where as for P-E Fit, the results of the present study were compared with the findings of Judge and associates (1994) as no meta-analysis is available based on the measure used. For the situational model, it appears that the correlations for the four job characteristic variables found in the present study were in line with the meta-analytic study by Fried and Ferris (1987) with one noticeable difference. The feedback-job satisfaction correlation had a larger magnitude than the correlation found by Fried and Ferris (1987) and the direct correlation found by Behson and associates (2000). For the dispositional model, the regression results found in the present study were in line the regression coefficients found in the meta-analysis by Judge and associates (2002). For the interactional model, the magnitude of the P-E Fit and job satisfaction relationship in the present study was similar to the results reported by Judge and colleagues (1994). Thus, it appears that the results of the present study were in line with the literature with one exception: feedback.

The results found in the present study regarding feedback suggest that feedback is an important antecedent for small business executives' job satisfaction. It also illustrates that research which

focuses on autonomy only, like Hundley (2001) and Naughton (1987), is limited in consideration of important situational factors influencing job satisfaction.

Comparing the interactional (P-E Fit) and dispositional (Big Five) job satisfaction models using the same sample, Tokar and Subich (1997) provided one of the very rare studies that directly compare job satisfaction models. These researchers found that neuroticism and extraversion were significantly related to satisfaction but P-E Fit was not. This is surprising as the commonly held assumption that the P-E Fit model is a superior model because it simultaneously considers both the person and situation was challenged by their empirically findings. Consistent with the findings by Tokar and Subich (1997), the present study showed that neuroticism and extraversion were significantly related to job satisfaction. However, in the present study the correlations between job satisfaction for neuroticism and extraversion, respectively, was larger in magnitude than found by Tokar and Subich (1997). Further, support was found, in the present study, for a significant correlation between conscientiousness and job satisfaction. The relationships between job satisfaction and neuroticism, extraversion, and conscientiousness, respectively, were also substantiated by the regression results in the present study. Unlike the findings by Tokar and Subich (1997), the present study found support for a strong and significant relationship between job satisfaction and P-E Fit; shown by the zero-order correlation and the regression coefficient. Further, the data fit the P-E Fit model better than the dispositional model (regardless of all five personality variables or only the three significant variables were considered) shown by the larger F-score for the interactional model in Table 2. Additionally, when the number of variables was taken into consideration, the P-E Fit model accounted for 16.6 percent of job satisfaction variance (adjusted  $\Delta R^2 = 0.166$ ,  $F = 6.876^{***}$ ) where as the dispositional model accounted for 13.9 percent of unique job satisfaction variance (adjusted  $\Delta R^2 = 0.139$ ,  $F = 4.132^{***}$ ). As this shows, the interactional (P-E Fit) model is superior in explaining job satisfaction than the dispositional model. This is consistent with the argument made in favor of the interactional model (Chatman, 1989). However, the results of the present study challenge the findings from the study by Tokar and Subich (1997).

Unlike the study by Tokar and Subich (1997), the present study also included the situational model. By finding that the situational model is also superior to the dispositional model, in terms of fit with the data and unique job satisfaction variance account for by the model, the present study moves beyond the study by Tokar and Subich (1997).

In sum, the present study makes important steps in advancing the literature by providing theory-driven explanations of small and medium-sized business executives' job satisfaction, by empirically challenging controversial findings found in an important study by Tokar and Subich (1997), and by providing empirical evidence on which of the three most recognized job satisfaction models is best at explaining job satisfaction.

## **Limitations**

Self-reported data are suspect of common method variance (Podsakoff & Organ, 1986). Thus, a Harman's One-Factor Test and a visual inspection of the correlations were conducted (Podsakoff & Organ, 1986). The Harman's One-Factor Test returned four factors accounting for 71 percent of variance. Further, no correlation was in excess of 0.58 between the independent variables. Thus, common method variance was not considered a serious threat to the present study.

Another limitation is the models tested in the present study were content models meaning that no mediators or moderators were included. Content models were used to make it possible to compare the three approaches to one another. Considering that it is the purpose of a study that should determine whether it is a process or a content model that needs to be examined (Behson et al., 2000), it was deemed appropriate to use content models for the present study. The last limitation considered here is the small sample size. As with all research, generalizing results must be done with care. As this study generated interesting findings based on a small sample size, additional research is called for to verify (or reject) the findings of the present study.

**ABSTRACT**

To elucidate the processes involved in the creation of new businesses, entrepreneurship researchers often turn first to the business founders. In principle, entrepreneurs possess information (especially concerning motivation and intentions) often unavailable to others. Because entrepreneurs are frequently contacted years after the business was being organized, there is risk that retrospective biases will adversely affect the data collected. One challenge is that events themselves change in the early days: entrepreneurs develop expertise, markets expand, strategic plans are modified. When the target of inquiry changes, it makes little sense to describe a correspondingly changed description as a “bias.” Another challenge is that entrepreneurs are typically not interviewed for several years running. Both of these difficulties are reduced in the Panel Study of Entrepreneurial Dynamics (PSED). One important item asked respondents to indicate their level of satisfaction with the job they held immediately *prior to* initiating their ventures. It is reasonable to assume that this inquiry target – the last job you had prior to starting your venture – remains stable. In the PSED there were four waves of data in which satisfaction with that job was assessed. The pattern of data over this four-year period showed a slight increase in satisfaction from Wave 1 to Wave 4. More importantly, recollections of satisfaction were also related to participant sex and nascency status (partially autonomous or fully autonomous). These results argue for more caution in the interpretation of entrepreneurial recollections: What they say now is not always what they would have said then.

**INTRODUCTION**

Researchers have often relied on entrepreneurs’ retrospective accounts as a means of reconstructing the entrepreneurial process or parts of the process (e.g., Bhava, 1994; Brockhaus, 1980; Hisrich & Brush, 1986) on the assumption that such accounts are reliable and valid. Entrepreneurs certainly have important information about the entrepreneurial process, often including details known only to them. Their retrospective reports are typically thought to establish facts, attitudes, beliefs, activities, and motives related to venture formation. These

retrospective accounts are often the basis for model testing and advancing our understanding of entrepreneurship.

Unfortunately, retrospective reports may not have shoulders broad enough to carry the burden they currently bear, although the potential problems have not been examined adequately in the entrepreneurship literature. Is what I tell you *now* about what it was like *then* really the way it was, or is it the way I would now like for it to have been? In the strategic management literature the impact of retrospective bias has been critically reviewed (Huber & Power, 1985; Schwenk, 1985) and empirically examined (Bukszar & Connolly, 1988; Golden, 1992), but in entrepreneurship the issue has been addressed (if at all) primarily as a potential limitation of prior research (e.g., by Carter, Gartner, Shaver, & Gatewood, 2003). Thus, the purpose of our study is to draw attention to the issue of retrospective bias in entrepreneurship research. Part of the difficulty, of course, is that in most cases “then” and “now” are collected at the same time. With four waves of data collection from the same nascent entrepreneurs, the Panel Study of Entrepreneurial Dynamics (PSED, data and descriptions available from the Institute for Social Research at the University of Michigan, at <http://projects.isr.umich.edu/pсед>) provides allows us to obtain a “then” that was really then, and a “now” that is really now.

## LITERATURE REVIEW

Four primary reasons for entrepreneurs to provide inaccurate or biased data were identified by Huber and Power (1985):

1. The entrepreneurs are motivated to do so.
2. The entrepreneurs’ perceptual and cognitive limitations and biases.
3. The entrepreneurs lack information about the issue of interest.
4. Inappropriate data elicitation procedure has been used.

Huber and Power (1985) point out that the first two data distortions are linked, because motivation influences perception and cognition, and perception and cognition set the stage for motivation. Motivationally influenced biases may be intentional or unintentional. Need for achievement and social acceptance may be reasons for providing inaccurate or biased data. Although no finding can be considered etched in stone, researchers beginning with McClelland (1965) have noted that entrepreneurs have a high need for achievement (more recently, a review by Johnson (1990) showed the relationship in 20 of 23 studies conducted with entrepreneurs. Thus, entrepreneurs may be motivated to show others that they are successful. As they report the successes to others they are also confirming their high achievement to themselves. This motivation to distort the data may also be due to social desirability (March & Feldman, 1981).

Entrepreneurs’ cognitive and perceptual limitations and biases (Baron, 1998; March & Simon, 1958) also play an influence in retrospective reports. People have imperfect recall of the past. For example, Wilson, Meyers and Gilbert (2003) found that recollection of positive events was subject to a focal bias where people think about the event in isolation and neglect to consider other aspects influencing the event. These researchers also found that a retrospective bias in recollection of negative events depended on whether the individual continued to rationalize the negative outcomes at the time of recall. Also, entrepreneurs may be susceptible to hindsight bias (Fischhoff, 1975). In three experiments, Fischhoff examined whether people could make the

empathic leap into the past when they knew the actual outcome. Not only did knowledge of the outcome increase the postdicted likelihood of events, the research participants were largely unaware that it had done so. Bukszar and Connolly (1988) examined hindsight bias in strategic decision making and found support for presence of hindsight bias. Especially in an arena – business – where success is very important, entrepreneurs are likely to be susceptible to the well-known self-serving attributional bias (Bradley, 1978). Indeed, this sort of bias has already been shown among participants in the PSED (Gartner & Shaver, 2002). Other perceptual distortions may influence recall that stem from the need for cognitive consistency which may affect recollection by removing or reducing inconsistencies between information and beliefs and from the need for simplification, condensation, and rationalization (Schwenk, 1985).

Few will contend that the new venture creation is not a complex process. Also, few will contend that the entrepreneur has full information regarding the new venture creation process and all its aspects, including ever changing market forces. As a result, entrepreneurs experience information overload in some areas and lack information in other areas. As discussed earlier, the experience of information overload is reduced through simplification and retaining information that is consistent with previous beliefs which in itself creates potential for recall bias. Also, lack of information may result in recall of unintentional inaccuracies. For example, second-hand information and imagination may fill information gaps that, in turn, may lead the entrepreneur unintentionally to report inaccurate information.

The data elicitation procedures may also cause unintended inaccuracies by limiting or biasing the information collected. Kahneman and Tversky (1979) speculated that the framing of questions may produce a recall bias. Their speculation was supported (e.g., Sprangers & Hoogstraten, 1989; Sudman & Bradburn, 1983). In a multiple-wave design, however, where the data collection procedures are identical across waves, question framing is a constant that will not affect responses from one wave to the next.

The biases and inaccuracies unique to the individual are of critical importance when studying entrepreneurship because, many times, the number of respondents who can report on the entrepreneurial process for a venture is limited. Thus, inaccurate or biased information introduced by one respondent is unlikely to be offset by another respondent in the same venture. So, how predominant is retrospective bias in accounts reconstructing the past? The strategic management literature may provide a first clue.

In a study of 259 CEOs of hospitals, Golden (1992) found that 58 percent of the respondents recollected incorrectly strategies they had reported two years earlier. What is most interesting is the extent of the retrospective bias found by Golden – nearly 60 percent of the respondents were influenced. Golden further examined the causes for the retrospective bias. He found that faulty memory or a desire for past behavior to look good could account for the retrospective bias, which is consistent with the work by Huber and Power (1985). Yet, to our knowledge, no study in the entrepreneurship literature has examined whether entrepreneurs are inclined to bias their retrospective accounts.

Fortunately, the body of entrepreneurship data now contains an excellent way to test for the presence of retrospective bias, the PSED. Because of its longitudinal design, participants in the

PSED were asked a number of questions concerning personal motivation once per year for as many as four years. The first interview occurred in the very early stages of business creation, subsequent interviews obviously occurred later in the organizing process. Many of these items might be expected to change over time, as the entrepreneurs gain experience, and success. On the other hand, there is one item that deals with something that does not change as time goes forward. That is the respondent's last job prior to beginning the entrepreneurial organizing. Because that job was effectively defined as over in the first wave of measurement, the *job itself* will not change as time goes forward. The respondent's *recollection* of it might change – indeed, we trust that it will. Because the stimulus is constant, alterations in the perception of it can be taken as evidence for changes in memory through time. .

## METHOD

The sample for the PSED was identified in random-digit dialing calls made by Market Facts (a national marketing company) to 64,622 U.S. households. These initial screening calls, made in successive waves of 1000 between July 1998 and January 2000, identified potential nascent entrepreneurs by their responses to two questions:

- Are you, alone or with others, now trying to start a business?
- Are you, alone or with others, now starting a new business or a new venture for your employer?

An affirmative answer to the first question identified potential nascent entrepreneurs, an affirmative answer to the second identified potential nascent intrapreneurs. Before being included in the sample, people were also asked whether (a) they expected some degree of ownership of the new venture, and (b) they had been active in organizing the business within the preceding 12 months. The screener identified a pool of individuals who were then approached by the University of Wisconsin Survey Research Laboratory (UWSRL) who conducted a full telephone interview with willing respondents, then sent a follow-up mail questionnaire. Participants were paid \$25 for the phone interview, and another \$25 for returning the mail questionnaire. Complete details concerning the PSED can be found in a recent book by Gartner, Shaver, Carter, and Reynolds (2004).

The numbers of respondents present in the sample at every stage have been described in detail by Shaver, Carter, Gartner, & Reynolds (2001) and will not be repeated here. The entire pool of respondents consisted of 830 potential nascent entrepreneurs and 431 people in a comparison group. Consensus among researchers investigating psychological variables in business creation is that the more appropriate sample is the 1,216 people (715 fully autonomous entrepreneurs, 102 partially autonomous entrepreneurs, and 399 members of the comparison group) identified by Shaver, et al. (2001).

The job satisfaction item used as our indicator of possible retrospective bias was included in the mail survey, not the telephone interviews, so our effective sample was limited to the 871 who had returned the mail questionnaire (an impressive 71.63% of those who completed the phone interviews). Questions about the respondent's job history began with mail survey item Qi2, "The last time you had a job working for someone else or in an established organization, what was

your job title?” After items about what the respondent did, how many years and months the respondent had held the job, and three items about the organizational structure, Qi8 asked “How satisfied were you with this job?” with answers scored as a 5-point Likert-type scale with response alternatives ranging from Very Dissatisfied (scored as 1), to Very Satisfied (scored as 5).

Now because we are interested in the backward-looking impressions of *entrepreneurs*, we next restricted the sample to the 545 people who were in the process of starting businesses and had answered the question about job satisfaction in the first wave of the research. This group included 472 fully autonomous entrepreneurs (241 females, 231 males) and 73 partially autonomous entrepreneurs (41 females, 32 males)

## RESULTS

One advantage of the PSED dataset is that it includes post-sampling stratification weights (based on such things as education, region, and age) that permit the aggregate data to be generalized to the U.S. population as a whole. Not only did the weighting procedures (described in detail in the Gartner, et al., 2004, book) take demographics into account, they also corrected for sampling biases and differential non-response within the first wave. Specifically, for example, half of the initial prescreening calls were made (with support from the National Science Foundation) to oversample people whose absolute numbers of business starts might not otherwise have been sufficient to permit detailed analysis. A grant to Nancy M. Carter (SOC 9809841 provided support for an oversampling of women, and a grant to Patricia G. Greene (SOC 9905255) provided support for an oversampling of minorities. By the very nature of these projects, there were alterations in selection probabilities (e.g., the process to oversample women was designed to produce essentially no male respondents). Again, consensus among the researchers directly involved in the PSED is that all analyses should use weighted data. Moreover, the weights should be renormalized whenever the whole sample is “cut” (e.g. into cells that involve nascency status and respondent sex). We have followed these recommendations, so all the analyses reported here are based on weighted data. (It should be noted that the weights are to correct for potential biases in *sampling*, not for attrition, so even where we report data from waves 2-4, the variables involved are weighted by renormalized versions of the wave 1 sampling weights.

Perhaps the most direct test of whether perceptions of one’s former job change over time is a 2 x 2 x 4 (Respondent Sex x Nascency Status x Wave) repeated-measures analysis of variance with Wave being the repeated measure. Remember that job satisfaction was measured on a 5-point scale with 5 representing “very satisfied.” The mean scores for respondent groups by PSED waves are shown in Figure 1. Two things are immediately apparent. First, there was greater

---

Insert Figure 1 about here

---

variation over time among partially autonomous females than among any other group of respondents. Second, with the exception of those partially autonomous females, the general trend was for recalled job satisfaction to increase slightly over time. Together, these outcomes produced a three-way interaction that was just a shade away from being significant,  $F(3, 537) = 4.80, p = .052$ . In other words, with the exception of the partially autonomous females, the view of one's prior job became a little more rosy as the job faded into the distance.

The difficulty with a repeated measures design, of course, is that it assesses the responses of only those people who were present for all four waves. In the first wave there had been 545 respondents, but by the fourth wave the number of always-present respondents was down to 183. Some respondents could be contacted in one wave, but not the next, and some who had been missed in a wave were contacted the next time around. As a result, the total numbers of respondents who answered the job satisfaction item were 545 (wave 1), 332 (wave 2), 290 (wave 3) and 334 (wave 4). To make use of as much data as possible, we did univariate 2 x 2 (Respondent Sex x Nascency Status) analyses of variance separately for each wave. The first three of these showed no significant differences based on sex or nascency status. Overall mean scores for remembered job satisfaction were 3.55, 3.63, and 3.63 (for waves 1-3, respectively). The overall remembered job satisfaction for wave 4 was 3.94, despite the fact that partially autonomous females had an average score nearly a point lower than that of the other three groups. This interaction was nearly significant,  $F(1, 330) = 3.47, p = .06$ . The picture provided by these separate analyses complements the one from the repeated measures analysis – by the fourth year away from it, one's prior job looks better and better.

## DISCUSSION

Under almost the best of circumstances, researchers find their way to existing entrepreneurial companies several years after the initial organizing effort. By the time an entrepreneurial company has created a niche for itself, generated positive cash flow for a year or two, and come to the attention of researchers interested in its organizing process, questions about “the beginnings” will necessarily be retrospective. As we noted earlier, both the general psychological literature and the strategic management literature provide reasons to be wary of such retrospective reports.

In entrepreneurship, by specific comparison to strategic management, there are often two structural reasons why it is exceedingly difficult to separate biased memories from accurate reflections. First, an existing firm that has a corporate *strategy* may very well have that strategy written down. Or might be of a sufficient size that the recollections of one respondent could be compared with those of another respondent also present at the time the strategy was devised. At the very least, the firm might be able to produce documents (or, increasingly, internal emails) that could serve as a form of contemporaneous record. Second, although no strategy is completely impervious to events, it does serve as a way for the firm to deal with those events. Thus, in the normal course of business, the strategy is likely to be “refreshed” from time to time. By contrast, in an entrepreneurial firm, the *organizing events* typically occur only once, early in the life of the firm. There might have been very few people there to observe them, they are

unlikely to have been refreshed through the years, and their interpretation is highly subject to modifications based on the current success of the business.

The challenge for entrepreneurship has been to find some “target” known to be stable, and then to ask entrepreneurs about that target over a period of several years. Because an entrepreneur’s *prior* job, the last one held before beginning the organizing activities, does not change, it can serve as a very stable target. And thanks to the longitudinal nature of the PSED, respondents were asked to recall their satisfaction with that prior job in each of four succeeding years. Whether the results we obtained show a cup that is half full or half empty may depend on who is making the judgment. True, during the first three years of organizing, reflections on one’s prior job were relatively stable, with a slight upward trend. In the fourth year, however, our respondent groups parted company. Partially autonomous females now viewed their prior job with decreased satisfaction; fully autonomous females and males in both autonomy categories now expressed increased satisfaction for their prior jobs. Thus, at least by the fourth year, one’s view of a constant past depended on both one’s sex and on the nature of one’s business organizing activity. People in the sample were still happy to tell us what they thought. It just wasn’t quite the same as what they had previously thought. The PSED was obviously not designed as a test of the existence of retrospective biases among entrepreneurs. But at the very least, these PSED data suggest that the problem of retrospective bias in entrepreneurship research deserves much more concerted attention than it has received to date.

\*\*Associate Professor at Department of Management Studies, I.I.T, Delhi.

**Abstract:** Intention to use Information Systems (IS) and perceived expertise in Information Technology (IT) can drive businesses in the SME world. An empirical study of knowledge entrepreneurs in India is done through an online questionnaire survey, which got responses from a heterogeneous sample of SMEs. Necessity is rated as a prime motivator for entrepreneurship by about 50% of the respondents. We found support to our hypothesis that external stimuli like lack of funding sources (negative stimulus) and stake holder's expertise in Information Technology (positive stimulus) motivate use of IS and Internet in small businesses. We also found a positive relationship between the measures of index of entrepreneurship and perceived use of IS in SMEs. Respondents who rated their products/services high on innovation also rated their expertise in IS and their utility for websites as high.

**Key words:** Information Systems, Small Medium Enterprises, Knowledge Entrepreneur

## Introduction

Use of computer based information systems (IS) in the business world and corporate world in India, has been growing at a momentum higher than that of other industries in the country. During 2002-03, the Information Technology (IT) -enabled services segment grew by 65 percent and revenues from this sector rose from around Rs. 71 billion in 2001-02 to approximately Rs. 117 billion in 2002-03. Has the use of IS and the resulting empowerment of the individual also resulted in a new brand of entrepreneurs who are essentially knowledge workers? Will there be a mushrooming of IT-enabled small businesses in the near future? These are some of the questions we address in our study.

The Small & Medium Enterprises (SME) sector is one of the fastest growing industrial sectors all over the world. However, the Global Entrepreneurship Monitoring Index (April 2003) rated India just above South Africa with an index of 0.04 in the high potential entrepreneurship area. Innovation and technology transfer leverage SME competitiveness in the global knowledge based society. India currently spends less than 2 percent of its GDP on IT, which is very low when compared to the US which spends 5 percent of its GDP on IT or France, which spends 2.7 percent of its GDP on IT. IT is more of an enabler in India than the cause for innovation. Knowledge is increasingly becoming, the world over, the most important factor determining our standard of life, more than land, tools and labour. Our study focuses on the knowledge entrepreneurs of India.

## **Literature Review**

Peter Drucker defines a 'knowledge worker' as- "Someone who knows more about his or her job than anyone else in the organization". Knowledge is the ability to transform our resources to our advantage.

The adoption and use of IT to achieve competitive advantage has received a great deal of attention in IS literature, but essentially in large corporations. Research dealing with just the large corporations creates a potential bias in substantive conclusions about IT because firm size can affect several crucial organizational processes. Most of the SMEs are controlled by individuals, unlike large firms where decisions of IT adoption are relegated to an IT expert. The IT expert and owner merge into one in the SME world. Our paper addresses the scarcity of research dealing with IS in SMEs -especially the lack of research on the contribution of online presence to growth and competitive edge in SMEs. Most IT adoption research dealing with small firms has been exploratory.

IS researchers have suggested that intention models from social psychology can provide a foundation for research on IT adoption by firms and IT usage by individuals. Ajzen's (1991) Theory of Planned Behaviour (TPB) is a well- researched intention model in predicting an important behaviour in a wide variety of domains. As the theory describes an active, deliberate decision process within the constraints of social expectations and limited resources, it is especially useful for studying the strategic adoption of IT in small businesses. In our paper, we empirically examine the capabilities of TPB to predict and explain how small businesses decide to adopt IT to grow and compete as entrepreneurs.

## **Methodology**

Harryson et.al (1997) write that research on IT adoption in small business should be flexible enough to involve a wide variety of ITs, especially when the sample is drawn from a heterogeneous population of SMEs. SME sector is defined as firms with less than 200 employees and whose turnover is less than RS 250 million, a definition acceptable to the funding agencies including banks in the country. Our study examines the responses to a questionnaire survey from a sample population of entrepreneurs in the SME sector drawn from India.

The questionnaire is administered online. Our instrument of survey consist of 12 questions, which measure entrepreneurial index, and ten questions on use and adoption of IT in general. In all, about 2000 emails were sent to SME addresses collected online from the Small Scale Industry website of the Govt. of India, the SME forum at the website of NASSCOM (National Association of Software and Service Companies) and from websites featured in yellow pages. The survey link was also posted on SME related yahoo groups online. We received 79 responses online and 19 offline. While sending emails, which are collected from the websites of the firms, care was taken to avoid back offices of foreign firms and subsidiaries of firms incorporated abroad. The sample of SMEs is thus made up of indigenous and independent entities, not belonging to any large corporate group. When we talk of adoption of IT/IS, we are not looking at a simple task oriented software package or application but a technology designed to meet immediate operational needs and technology as a long term strategic competency.

## Research question

The broad research question we address is “ Does the use of IS motivate knowledge entrepreneurs?” The following hypotheses associate the degree of adoption with a measure of entrepreneurship.

### Hypothesis 1

In SMEs, decisions (intentions) to use IS are a positive linear function of External stimuli and perceived control over adopting IS.

### Hypotheses 2

The degree of adoption of IT in SMEs is a degree of the measure of entrepreneurship of the chief executive.

### Hypotheses 3

Perception of risk/threat is a deterrent in adopting new technology in the case of SMEs.

### Hypotheses 4

Infrastructure bottlenecks cost and hygiene factors are deterrents to use of IS

## Results and analysis

Out of the 88 responses received 31 are from manufacturing, 29 from services, 18 from IT services and 10 from traders. The locations of the firms are widely spread covering major cities of India, having a population of more than 1 million. 70% of the respondents claimed average and good expertise in use of computers. 25% claimed good to professional expertise. 60% of the respondents had no IT training. 80% of the respondents employed less than 50 people. Only 4.5% employed more than 200 people. 50% of the respondents agreed to necessity being the motivator for becoming an entrepreneur. 74% of the responses came from profit making concerns.

The 22 questions in the survey (**Appendix I**) assess the entrepreneurial index of the respondent and the perceived and actual usage of IT in the firm. While all SMEs are run by entrepreneurs, the motivation for becoming an entrepreneur can vary. The first ten questions assess the motivational causes for becoming an entrepreneur on a Likert scale of 1-5. Seven questions refer to the perceived and actual use of IT. Five questions measure the entrepreneurial index of the respondent. For formulating the questions on entrepreneurial index we borrowed heavily from the First Annual Global Entrepreneurial Symposium held on April 29, 2003 at United Nations Headquarters. The responses we received are from owners/stakeholders. Only 11% of the respondents reported having no stake in the firm.

A bi-variate correlation matrix of the variables using Pearson's correlation coefficient and two-tailed significance test is given in **Appendix III**. Correlation coefficients where where  $p < .05$  are shown in red. **Appendix II** lists out the variables used in the matrix.

The major findings of our empirical study are given below.

1. 50% of the respondents had agreed to necessity being the motivator for becoming an entrepreneur. Necessity showed strong positive correlations with seeing an opportunity and opening up of the market. More than 74 % of the respondents started their business after 1991 when the Indian economy started opening up. Necessity and stake of the entrepreneur also showed strong correlations significant at .016, but in the opposite direction. ( $r=-.2573$ ,  $p=.016$ )
2. Those who rated IT training as a major motivator to become an entrepreneur, rate the possibility of their business depending on high speed internet high. ( $r=.2567$ ,  $p=.016$ )
3. Those who rated the availability of funding as least important motivator to become an entrepreneur, rate their expertise on usage of IT as high. ( $r=-.2881$ ,  $p=.006$ )
4. Those who rated the availability of funding as the least important motivator to become an entrepreneur, rate the maximum usage for IS in their firm. ( $r=-.3860$ ,  $p=.000$ )
5. Those who rated the availability of funding as the least motivator to become an entrepreneur, rate usefulness of website beyond a mere 'web presence' as high. ( $r=-.3255$ ,  $p=.002$ )
6. Entrepreneurs who perceived innovation of product/services high also rate dependence on high speed internet high. ( $r=.3333$ ,  $p=.002$ )
7. Entrepreneurs who rate innovation of product/services high also rate their expertise in IT high. ( $r=.3820$ ,  $p=.000$ ). Their perception of website going beyond a mere presence was also high ( $r=.3144$ ,  $p=.003$ )
8. Those who rate high on entrepreneurial index also rate high on expertise in IT ( $r=.3504$ ,  $p=.001$ ) and use of IS ( $r=.3580$ ,  $p=.001$ )
9. Those who rate high on entrepreneurial index also tend to allocate more funds for IT. ( $r=.3475$ ,  $p=.001$ )
10. Those who rate their expertise in IT high also rate use of IS high ( $r=.2829$ ,  $p=.008$ ), also rate IT allocation as high ( $r=.4192$ ,  $p=.000$ ) and also rate the percentage of IS staff in the firm high ( $r=.3286$ ,  $p=.002$ ).

### **Hypotheses revisited**

Results 2-6 support our first hypothesis namely, in SMEs, decisions (intentions) to use IS are a positive linear function of

- a) External stimuli
- b) Perceived control over adopting that IS.
- c) Learning curve of the executive who takes decisions.

Funding for small enterprises and startups are hard to come by in India. Interestingly, this lack of external funding seems to spur individuals to start IT enabled businesses.

Result 7 gives indirect support to the first hypothesis – The more the perception of innovative products and services in the CEO's mind, the more the rating for his expertise on IT and for using the website of the firm as more than an online presence. Since innovation is a strong index of an entrepreneur, this supports our broad research question namely, use of IS motivates knowledge entrepreneurs.

Results 8, 9 and 10 support our second hypothesis, namely the degree of adoption of IT in SMEs is a degree of the measure of entrepreneurship of the chief executive.

Hypotheses 3 and 4 are not supported.

### **Limitations of the study**

- The questionnaire is attempted online. This presupposes availability of good internet access to the respondent. About a third of the responses were collected offline to offset this limitation to some extent.
- The sample size could be bigger. The decay rate for online responses is normally as high as 98%. (Terri C. Albert et. al.) In our case the responses are about 3% of the mails sent, which resulted in our using a fairly small sample in testing our hypotheses.
- The study can be enriched by getting the figures for actual increase in entrepreneurial SMEs over the last, say five years in India- the period when adoption of IT use of IS has increased. . However public records for SMEs are difficult to come by especially for tiny and micro enterprises.
- There is need to have a common definition of SMEs applicable universally.

### **Research Directions**

It will be interesting to extend the research to impact of IT/IS on clusters of micro enterprises and on the social entrepreneurs in particular. Further insight can be obtained by extending the survey to the Asia Pacific region as a whole. The region as a whole is characterized by necessity driven entrepreneurship and the role of IT/IS in realizing the full potential of the knowledge entrepreneur needs to be examined.

### **Conclusions**

Intention to use Information Systems (IS) and perceived expertise in Information Technology(IT) of individuals can drive businesses in the SME world. In our study, IS use is examined at a micro level, one that involves users or decision makers - this is a context in which the diffusion of technology is paramount. In today's environment, many applications that become strategically important can begin as standalone programs designed and used by end users. Eventually, through initiatives by management or by the users themselves, these applications are identified as being important to the success of the firm, not just to the individual user. Leveraging this technology, many an individual user goes on to expand the level of operations - and an entrepreneur is born. Our empirical study lends support to this theory. We have identified some variables, which influence this migration from an individual to an entrepreneur; IT training, availability of high speed internet and funding or lack of it- are some of them. How prevalent is this phenomenon in present day India where IT adoption is still in transitional stage? This needs to be further examined in the light of secondary data available with SME forums and associations. Empirical

evidence supporting the research question can be extended further with the help of TPB to arrive at deliverables to foster entrepreneurship in the country.

According to NASSCOM, IT industry contributes about 3% to the country's Gross Domestic Product (GDP). Approximately 15% of the contribution to this revenue comes from SMEs. They expect the percentage of contribution by SMEs to grow upto 60% by 2008. Our research will help to plan this growth in a structured way.

The CEO whose expertise in IT is high also allocates more funds to IT (Result No.11). The advantage of the IT expert and CEO merging into one is immediately translated into action. This is corroborated by the fact that 48 percent of total tech spending of IBM South in India comes from the small and medium scale enterprises. (Figures 2004).

Understanding the distinct behaviours that entrepreneurs practice in developing decision processes and information systems provides a conceptual framework for further academic research on the SMEs. The study also provides a practical framework for use by individuals involved in startups.

Information Systems in Small Medium Enterprises in India

# **CREATING INNOVATIVE SMES: IS COPYING THE SINCEREST FORM OF FLATTERY?**

**Peter Sheldrake**  
**RMIT University, Melbourne, Australia**  
[peter.sheldrake@rmit.edu.au](mailto:peter.sheldrake@rmit.edu.au)

Much of the literature on innovation and entrepreneurship assumes that innovative smaller companies are essentially start-ups, where an entrepreneurial individual has seen a business opportunity and created a business to meet this opportunity. On the other hand, research on larger companies has examined the factors that promote innovation and entrepreneurial activity, including extrinsic issues (ranging from government policy to the competitive environment), internal systems and processes, and the development of staff and managerial capability. Case study research in Australia supports findings for larger companies. Moreover, in the case of smaller companies many of the same factors are important, and SMEs appear to face the same challenges as larger companies in developing new or entrepreneurial areas of activity. This paper compares findings from research on larger companies to the characteristics of the SME sector. It identifies those factors that are comparable between large and smaller companies in affecting the propensity to be innovative and entrepreneurial, and highlights two key areas where there differences exist.

## **Introduction**

Research on innovation and new venture creation confronts a literature that has grown exponentially in recent years. As a result, terms and concepts have elaborated, and there are increasing definitional challenges, as a number of writers have commented (eg. Hitt et al, 2002; Shane and Venkatamaram, 2000; and Garcia and Calantone, 2002). In many cases the word 'innovation' is restricted to ideas that have been realised in the form of a product or service for which there is a potential market. However, others have taken a broader view, where innovation is also taken to include changes in the processes and systems of the organisation itself, (Innovation Summit Implementation Group, 2000). Following this more recent general practice, the term 'innovation' will be used in this paper to include product innovations, process innovations (which may be internally focussed or relate to customer service processes), and business model innovations, (see Hamel, 2000). Further, where appropriate a distinction will be drawn between those innovations that may be described as incremental (or sustaining, continual improvement), as opposed to those termed radical (discontinuous, revolutionary or disruptive) (see, among many others, Christensen, 1997, Christensen and Raynor, 2003; Tushman and O'Reilly, 2002).

A further definitional issue relates to entrepreneurship. For some writers the definition of innovation includes not only a new product, service or process, but also

encompasses the development of a business around that innovation. Again, following what appears to be the dominant practice, the word innovation will be restricted to the opportunity, and the term 'entrepreneurship' will be used to encompass the process of building a new business, irrespective of whether or not that business is based on an innovation, or on an existing product or service, (cf. Timmons, 1999; Stevenson et al, 2000). In particular, the focus will be on entrepreneurial capabilities, and the factors that seem to influence these in both large and small organisations. This paper reports on work in progress, and is based on a series of case studies of both large and small organisations (some of these case studies have been previously described – see Sheldrake, 2004, Sheldrake and Fazzino, 2003)

### **Corporate innovation and venturing**

As noted above, there is a growing and important literature on innovation and entrepreneurship, and considerable attention has been paid to the development and practice of these capabilities in larger organisations, particularly in relation to:

- structural issues that face larger companies seeking to be innovative;
- different approaches to innovation in relation to the life cycle of the product or service a company offers; and
- the importance of organisational culture, and the extent to which the nature of the systems and processes inside organisations are themselves an inhibitor in relation to innovative thinking.

Interestingly, rather less attention has been paid to the characteristics of innovative and entrepreneurial people in large organisations, although there is a long research tradition in looking at the management and support of research and development staff (e.g., for example, the key research of Pelz, in Pelz and Andrews, 1966).

In relation to structural issues, the major issue that has drawn attention has been whether it is more effective to establish separate innovation units or project teams (see, for example Mintzberg and Quinn, 1991, Tushman and O'Reilly, 2002), or to establish innovation as an organisational compatibility that should be found throughout the organisation (Christensen and Raynor, 2003, Hamel, 2000; Utterback, 1994). A particularly helpful overview of various structural models is given in the work of Leifer et al (2000). Case studies of successful innovation reveal that to a significant degree organisational structures are more important in inhibiting innovation, rather than promoting it, and this has led writer like Hamel to comment on the importance of what he calls 'activists' (Hamel, 2000; cf related work on the concept of the organisational 'Ronin', Sheldrake, 2003).

The second theme, looking at the relationship between innovation and the life-cycle of products and services has seen considerable development in recent years – especially with the work of Christensen and Raynor looking at the factors that seem to influence the successful opening up of new markets (Christensen and Raynor, 2003).

However, it is the third area, research on the culture of organisations and the impact of that culture on innovative and entrepreneurial thinking, which has been a major area of interest over the past decade. One dominant approach has been the rationalistic strategic model, where organisations are seen as a portfolio of resources and competencies (Hamel and Prahalad, 1994), and business planning is concerned with assessing environmental and industry requirements, competition and the

alternative uses of resources and competencies to achieve maximally effective competitive positioning. Drawing on Porter (1980), there has been an extensive development of systematic approaches to competition and the use of competencies (see, for example, Christiansen, 2000; Zack, 2002; Shapiro, 2001: and Brown and Eisenhardt, 1998).

While this approach has led to sophisticated strategic analysis models, a second approach has been to look at culture in a broader framework, as a basis for establishing the values, ways of behaving and values that characterise the priorities and focus of the organisation. This has led to a number of studies looking at the 'internal environment' of innovative companies, ranging from seminal work by Drucker (1985), through to more recent studies by Tushman and O'Reilly (2002), Collins and Porras (1996), Clarke and Clegg (1998), and Seely Brown and Duguid (2000).

A particularly important study was undertaken by Kuratko et al (1990), which surveyed a number of leading firms and identified five actors that appeared critical in establishing a climate conducive to innovation:

- senior management commitment
- a willingness to take risks
- structure
- incentive and rewards
- resourcing.

In a similar fashion, Tushman and O'Reilly conclude that both structure and culture must be aligned to ensure effective innovation (1997). Again, while these are clearly important factors, they sidestep the question as to who is going to make use of this environment, and the challenges facing a creative and innovative person working within a well-structured organisation: activists seem to flourish in spite of (and sometimes in opposition to) organisation cultures that are far from conducive to creative thinking and ideas, (Hamel, Sheldrake, *op cit*).

More recently Garvin has tried to summarise the range of issues explored in recent research under 10 propositions that summarise the challenges facing the company that wants to become innovative. These propositions are:

1. Growth means starting new businesses
2. Most new businesses fail
3. Corporate culture is the biggest deterrent to business creation
4. Separate organisations don't work – or at least not for long
5. Starting a new business is essentially an experiment
6. New businesses proceed through different stages requiring different management approaches
7. New business creation takes time – a lot of time
8. New businesses need help in fitting in with established systems and structures
9. The best predictors of success are market knowledge and demand driven products and services
10. An open mind is hard to find.

(Garvin, 2004, pp 19-21).

Research on Australian companies has confirmed that Garvin's summary is helpful. Case studies in the chemicals, power, motor car industries have revealed these same factors are relevant, and that corporate structures, culture, and an underlying systemic focus on sustaining, incremental innovation act as significant barriers to innovation and corporate ventures, even when carefully developed schemes are introduced to support new business development (see Sheldrake and Fazzino, 2003, for a detailed case study in the chemicals industry).

### **Innovation in the SME sector**

In contrast to the research on innovation and venturing in larger companies, the focus of much of the research on innovation in SMEs has quite a different starting point. The challenges of dealing with routinised processes in large organisation seeking to be innovative are contrasted with the nimble, non-routinised behaviour of potentially disruptive small companies (see, for example, the discussion in Christensen and Raynor, 2004, on disruptive innovation). Given this, it is not surprising to find that many of the themes in the literature concerned with the innovation and entrepreneurial behaviour in SMEs are quite different, focussing on topics which include:

- The capabilities – or traits – of entrepreneurs, or business founders
- The processes and systems that identify and allow choice between opportunities (opportunity development and opportunity analysis)
- Business planning
- Funding.

Research on these themes is well summarised in a number of texts (e.g. Stephenson et al, 2000; Timmons, 1999).

Between 2002 and 2005, three case studies were conducted, looking at innovative SMEs, (more details on the three cases are in Sheldrake, 2004), with a particular interest in looking at the factors that inhibited or discouraged innovation business development. The case studies illuminated a number of issues.

First, despite their small size and relative short periods of business, there was considerable resistance to change, and to stepping out of their (relatively newly created) 'box'. For example, one company, in the food industry, manufacturing sports drinks and bars, identified an opportunity in responding to 'weight conscious' consumers, and decided to develop a new range of products in this area. Having identified market needs, new distribution channels, and product opportunities, within a year the opportunity was slowly dragged back to making an incremental change to the existing business. What had been an innovative business development had changed:

- while market research had identified a new market, the actual products were seen as an extension of the existing range
- branding was a challenge, with uncertainty over the extent to which this should be a new brands (or sub-brand), or should continue to be marketed through the existing and well-established brand
- entry into the new distribution channel was slower and more difficult than expected, and a reversion to the existing distribution channels was taking place..

Having defined a quite new business area, to a large extent, this company's existing operational models and approaches have re-defined the approach to the 'new' business area in a way that mimics its current operations.

Second, the ability to see new product development as 'experimentation' is critical. A second case study, looking at a small company in the entertainment industry, found that for 18 months, every proposed new venture quickly declined and failed, and the response was to cut costs and focus even more on the core business. In late 2003, the approach was changed, and new ventures are seen as 'experiments', as market trials, from which learning could be derived. Funded and supported as experiments, new business possibilities were given greater freedom, and some successful ideas were enabled.

Third, no amount of nimble behaviour can bypass market knowledge and demand driven approaches. In a second organisation, also in the entertainment industry, the core team sought to change audience by offering a quite different mix of products. However, this 'supply driven' approach was only partially successful; while the new approach did increase the number of younger people attending events, the established older audience did not continue to attend as they had in the past, and overall there was a dip in numbers. Poor market research had led to imperfect product selection, and when better demand driven planning was used in the following year, audience began to recover. To borrow from Jim Collins, being a 'fox' was no substitute for being a 'hedgehog' (cf. Collins, 2003).

### **Assessing the challenges**

While three case studies can only be illuminative, it is interesting to consider them through two quite different lenses. The first is that conventionally used in looking at innovative SMEs, and the second is the framework derived from research on larger companies.

From a conventional point of view, these three case studies are unexceptional. Each company was run by an entrepreneur, and in two of the three cases, entrepreneurs with a track record of success and failure. In each case, opportunity evaluation was linear and justificatory: the entrepreneur felt that the business ideas (new products, new approaches) were 'right', and in each case collected data to substantiate the potential market, potential return, and potential competitive opportunity. In none of the three cases did the entrepreneur assess the proposed innovation against others. In each case, interviews with the entrepreneur revealed that they lived with the expectation that 'the market would decide'.

On the other hand, there were a number of issues that did not surface in planning. There was a lack of awareness of the unwillingness of the companies concerned to abandon their relatively new ways of doing things: indeed, in two cases there was a focus on developing SOPs (standard operating procedures) at exactly the same time as the innovations were being brought to market, in the belief that the SOPs would make them work better – rather than allowing new ways of operating to be developed alongside the implementation of an innovative approach. Another issue that was not recognised was that in asking the same staff who were responsible for the on-going

business to also address the new business developments exacerbated unwillingness to allow creative and innovative ideas to flourish.

These three cases exemplify many of the observations made by researchers looking at new venture creation. However, another lens through which to view these case studies is provided by Garvin's summary of the experience of larger companies, and his ten propositions. Here, the comparison proves most interesting.

Overall, eight of the propositions that are put forward for large organisations seem to make equally good sense when applied to these smaller organisations. Of course, in some cases, that is because the propositions are self evident. For example, it is evidently the case that "*Most new businesses fail*" and that "*New business creation takes time – a lot of time*". These do not require further comment.

Some of the other propositions are more interesting, and yet still clearly relevant. First, "*Corporate culture is the biggest deterrent to business creation*": in these three case studies, this proposition is evidently borne out by the innovation histories that were observed. For all three companies, their existing cultures were a barrier to innovation. In the case of the food company, they sought to enter a new market and change their business in this area, but gradually moved back to more of an 'extension of existing business model'. In the case of the two entertainment companies, they were unable to recognise that their culture no longer saw innovation as the centre of the business – once this was recognised, it seems that the chances of successful experiments have gone up. This is closely related to another proposition: "*Starting a new business is essentially an experiment*". Over time, all three companies began to see new business development as experimentation, and as this perspective became more broadly accepted, so they were able to accept failures in start-up ideas, and become more willing to trial several experiments. This was particularly evident in the entertainment company, which now sees its core business as running experiments, and then building on those that work. For the food company, the realisation came late in the process, and it is still grappling with an effective path to develop its new business area.

The next of Garvin's propositions was the observation that "*Separate organisations don't work – or at least not for long*". Small companies do not usually have the luxury of resources that allow them to set up separate units or areas of activity opt promote innovation. However, while a separate group developing the new product line could have helped the food company in the short term, in the long term, reintegration would have been a challenge, as limited resources in areas like marketing, distribution and sales would have required that some people worked across business activities.

The preceding proposition links to another, that "*New businesses proceed through different stages requiring different management approaches*". This might be considered another self-evident proposition, as it is generally agreed that small businesses need quite different management strategies as they move from 'start-up' to 'growth' to maturity', and this developmental process tends to conflict with the challenges of managing innovation as this is taking place. For example, the food company was going through an overall consolidation phase, adopting more routinised

processes and procedures at just the same time as its innovative developments needed a quite different approach.

A particularly interesting proposition is that “*The best predictors of success are market knowledge and demand driven products and services*”. While scarcely surprising, it was striking how hard this was to keep in mind in the case of these three small and growing companies. While this is paradoxical, it is not surprising. In all three companies, there was a clear realisation that the business survived (or not) only to the extent that it met customer needs. On the other hand, management was busily trying to ensure costs were contained, systems put in place and followed, policies and procedures implemented. This is an essential and unavoidable tension: a in larger businesses, the organisation has to ‘work’, and at the same time, success can only come from developing new ways to meet customer needs and aspirations. The only difference between smaller and larger companies is that in the smaller company, getting policies and processes in place is a management challenge; in larger companies, keeping those policies and procedures in their place is the challenge.

Perhaps this is also the point at which research on the attributes of entrepreneurs is also relevant: entrepreneurs often ‘know’ there is a market for their innovative product or service, and are only proved wrong by experience! This slightly cynical observation has to be balanced by consideration of another of Garvin’s propositions, which is that “*An open mind is hard to find.*” In the case of these three companies, all three founder entrepreneurs has a remarkably open-minded approach, and as a result reported on constant battles they had to keep the rest of their staff working effectively, and yet not lose sight of the bigger picture. In larger companies, these two roles can be separated (as with the increasingly common practice of separating the COO role from that of the CEO). In a smaller company, this is very hard to achieve.

There are two areas where the applicability of Garvin’s propositions to SMEs needs to be reconsidered. First, he suggests “*New businesses need help in fitting in with established systems and structures*”. In many cases, smaller companies do not have well-established systems and processes, and are often battling to get these in place as the company moves towards a more stable basis of operation. In the case of the entertainment company, this was particularly important. As noted earlier, alongside a growing realisation that the business is about experimentation, the management has been trying to establish ‘standard operating procedures’. Thus smaller companies are busily trying to put into place the very same set of policies and procedures that the larger ones are trying to overcome. This leads to a dissonance between innovation and the need for a solid and secure basis for organisational effectiveness that makes the CEO’s role in a smaller company particularly challenging.

Second, another proposition is that “*Growth means starting new businesses*”. Clearly, for a small business, this is a contestable statement. Most larger businesses have developed from smaller ones that have grown through increased market share, and through product or service enhancement. Clearly, for the food company this is the case. It is less evident in the case of the other two organisations, where significant growth seems to come from really innovative ideas that ‘change’ the business, rather than simply doing more of the same. Overall, it seems likely that smaller companies will be unwilling to start new ventures while they seek to build up their income and profitability. Limited resources, and the dependence for success on making what is

being done today work well means that the capability to experiment is even more limited.

### ***Summary***

By and large, researchers looking at innovation and entrepreneurship tend to focus separately on new venture creation and start-ups and on larger companies. *A priori*, there are some good reasons for doing this: while new ventures are built around establishing a product or service – which is often (but not always) innovative, the challenge in larger corporations is to shift from focussing on sustaining innovations, and to look for new areas of business. However, while they can only be indicative, these three case studies of small new ventures in Australia suggests that the models being developed to make sense of innovation in larger corporations can be helpful in understanding the issues confronting SMEs. Small, even emerging businesses, face an immediate demand to establish policies and procedures that ensure consistency, quality and predictability, and very rapidly face challenges that, in many areas, are essentially the same as those faced in major corporations. This suggests there may be scope to draw on a lot more of the emerging theory on innovation in large companies in seeking to understand start-ups and new venture creation, and that theories about the different management needs of companies as they move from a start-up to a mature phase of operations may mark some important consistencies at every stage.

Existing theory is extended to predict the effectiveness of strategies for structurally reducing work family conflict by manipulating roles, given the salience of work and family roles and the resources available to the female entrepreneur. A conceptual framework is presented to examine the following question: Do female entrepreneurs who achieve high growth in complex service industries choose more appropriate strategies for reducing levels of work-family conflict than those who desire high growth, but are unable to achieve it?

Three basic strategies for manipulating roles are identified: 1) role elimination, 2) role reduction, and 3) role sharing. It is proposed that women who successfully develop high growth businesses will more effectively reduce work-family conflict by choosing strategies that better match their family salience and access to external resources than their less successful counterparts. It is further advanced that work family management strategies are a significant determinant of venture growth, and that role sharing strategies are preferred by most women since they permit women to enjoy the enhancement of both work and family roles while reducing the level of interrole conflict. As a result, it is purported that the high prevalence of team-building and participative management practices observed in women-owned businesses is driven by the need for female entrepreneurs to manage work-family conflicts as well as genetics or socialization.

# **VENTURE CAPITAL INVESTMENTS IN FAMILY BUSINESSES: THE FINANCIER PERSPECTIVE**

## **ABSTRACT**

This article summarizes findings of the exploratory study investigating the rationale behind the venture capital (VC) investments in family businesses (FBs) from the financier's perspective. The empirical evidence was gathered in the qualitative interviews with seven investment directors of Finnish VC firms. The findings of the study suggest that FBs represent a considerable share of the portfolio of VC firms and that venture capitalists (VCs) perceive this type of organization as an important source of deal flow for their funds. Although sustaining that assessment criteria for FB proposals do not differ from the ones used for the evaluation of other types of business organization, VCs recognize that FBs present particular organizational and cultural features that can increase the level of complexity and risk for their investments. Despite the additional risk involved, most of VCs remain interested in investment proposals from FBs, especially those FBs at the succession or exit phase. While in the case of non-FBs VCFs usually structure deals consisting in a mix of equity and debt instruments and demand exit strategy that includes the possibility for the VCF to force the sell of 100 percent of the business, some VCs revealed openness to structure deals with FBs using instruments that respect the objective of some families to maintain ownership and management control over time.

## **INTRODUCTION**

Why some venture capital firms do finance family businesses while others do not is the question motivating the present study. Despite the fact that family businesses (FBs) are the most prevalent form of business organization in the world, the knowledge on the role that external sources of equity play in this type of organizations is still rather limited. The evidence gathered in previous research analysing venture capital (VC) from the point of view of family business (FB) suggests that this type of firms rely less on VC than non-FBs (Poutziouris, 2001) and that family owner-managers are reluctant to use VC due to their fears of losing ownership and management control (Poutziouris, 2000). The knowledge about the VC investment in FBs from the perspective of venture capital firms (VCFs) is limited to findings of one empirical study (Upton & Petty, 1998, 2000). It was carried out in the US and focused specifically on the decision criteria used by VCs when assessing proposals of FBs in succession phase. The study found that VCs are eager to participate in FB successions and that the attractiveness of the investment opportunity is largely determined by the quality of the successor and the firm's growth potential. One important reason why some VCFs are reluctant to invest in FBs is that they do not consider FBs as sufficiently growth oriented businesses. Incited by these findings, the present study was designed to generate the knowledge about the VCs' perception of FB deals at a more general level and in VC markets other than that of US. Using Finnish VC market as a context, this article explores the rationale

behind the VC<sup>1</sup> investments in FBs from the financier's perspective and shed light on how VCs adjust to the particularities of FBs.

## **LITERATURE ON VENTURE CAPITAL DECISION MAKING CRITERIA**

There exist a number of studies that have sought to understand how VCs assess and select investments proposals and a variety of methods have been used to reveal the criteria involved in this process. In the literature on VC decision making, the criteria discussed are viewed as being associated with the proposals under analysis and the profile and strategic objectives of the VCFs.

Regarding the criteria associated with the investment proposals, one of the first studies (Wells, 1974) detected that management commitment is the criterion having the heaviest weight in VCs' assessment of proposals, other relevant criteria being the product, as well as market and marketing skills. In the study by Poindexter (1976) it was found that the criterion ranking the highest in the opinion of VCs is quality of management, followed by expected rate of return and expected risk. Similar results were obtained in studies by Tyebjee and Bruno (1981) and MacMillan et al. (1985). Applying non-compensatory actuarial models to both VCs' judgement and the actual outcome of ventures, Khan (1987) suggested that the entrepreneurs' desire to succeed and the uniqueness of the product are the variables of essential importance for VCs in arriving at their judgement regarding the financing decision.

Rather than being related exclusively to the perceived quality of the proposals, some further studies suggested that the decision-making criteria of VCs are also strongly influenced by the profile and strategy pursued by the VCF. Using verbal protocols, a method that consists in asking the research participants to verbalize their thoughts as they perform a particular task, Hall and Hofer (1993) discovered that in the initial proposal screening, one of the most important evaluation criteria applied by the VCs was whether or not the proposal fits the venture firm's financing policy in terms of business development stage, size of the investment, geographical location or industry.

## **METHOD**

The findings reported in this article are based essentially on the evidence gathered through interviews carried out with seven VCs from five Finnish VCFs during the summer 2004. The common characteristic of the VCFs included in this study is that at the time of the interview they had invested in at least one FB, here inferred as a business where more than one family member were involved in company's management. In addition to this, the VCFs investigated present variation in terms of the geographical focus of their investment: two of the firms focus on investment at a regional level, two others invest nationally, and the remaining one operates also internationally. Table 1 summarizes the basic information concerning the VCFs.

---

Table 1 about here

---

The five VCFs included in this study represent 11 percent of the total number of VCFs operating in Finland, employing 26 percent of investment professionals of the area, and managing 27 percent of the VC funds, which represent 48 percent of the capital under management. Their current portfolio comprises more than a quarter of all the Finnish businesses backed by the VCFs operating in the country. At the end of the year 2003, there were 46 VCF operating in Finland with € 3144 million capital under management and 576 Finnish companies in their active portfolio (Finnish Venture Capital Association 2004).

The seven VCs interviewed in this study were investment directors of one or more FB deals, three of them being managing directors of the VCFs. With each respondent a semi-structured one to two hour long interview was carried out using a general interview guide as a basic checklist.

In the following section the main findings of the study are presented. Safeguarding confidentiality, the identity of the participants quoted in this report is not revealed.

## FINDINGS

### Significance of Family Businesses in VCFs' Portfolio

To open up the discussion on VCFs investment in the FBs and to infer the significance of FBs in the overall investment portfolio of the VCFs the participants were provided with the list of investments (found on company's website) and asked to indicate which of their firm's current and past Finnish investments would they consider investments in FBs.

---

Table 2 about here

---

Taking into account that about 80 percent of the total number of Finnish corporations are FBs (Veaceslav & Lehtinen, 2001) the figures depicted in Table 2 suggest that in the portfolios of the VCFs FBs are comparatively underrepresented<sup>2</sup>. Despite of that, it is important to note that FBs correspond to a significant share of the VCFs' investments. If aggregated, data from the five VCFs investigated show that FBs represent over 20 percent of the total number of investments in their active portfolio.

After having identified the FBs that have received their firm's investment, the participants were asked to rationalize about why from all the businesses on the list they classified those as 'family' businesses. Encouraged to explain their own concept of FB, the participants emphasized such factors as 1) strong influence of the family in the decision making process; 2) having the majority of the shares of the company in hands of the family; 3) more than one family member working at the company; 4) the family envision the transfer of the business ownership to the next generation.

The important aspect discerned in the interviews was that some companies identified as FB at the moment of the interview were not perceived by VCs as such at the moment VC investment

decision took place either because the family dimension was not yet present or it was intentionally or unintentionally concealed from VCs.

*“... at the time when we entered the company we were not so aware of the family interest – we suspected and we even asked about it: do you have such interest? And then it turn out that they really have a very strong family interest! The grandfather (is) very strongly participating in the decision making and (has) a very strong interest in keeping the business in the family ...”*

### **Family Businesses as a Target Group?**

Although FBs statistically represent an important part of the VCFs' investment portfolios, the participants feel that their firms do not target family businesses as such. Nevertheless, they do consider this type of businesses as a potentially important source of deal flow for their funds, especially so, because of the high number of Finnish FBs that are expected to face succession issues in the coming years reported in press and by the Family Business Network. While two of the participants said their VCF only consider investments in FBs in which the family is ready to sell out the business (e.g. due to the lack of successor), the others were convinced that their VCFs could support also other alternatives such as financing the family generation transfer.

In participants' opinion the comparatively low number of VC backed FBs is more due to the attitudes of the FB owners than those of a VCF: the participants believe that many FBs are not keen to consider VC as a financing alternative, because they tend to be reluctant to sell ownership to outsiders. VCs also think that although FBs may have as much growth potential as non-FBs, some families pursue other objectives that limit or hinder the growth potential of the business:

*“They often have the growth potential - they have a lot of that potential in there! It's just that the family orientation impose such restrictions that they cannot use the potential.”*

### **Assessing Family Business Proposals**

The participants' general opinion was that they assess FBs proposal the same way they assess any other investment proposal. From their point of view their decision making criteria continue to focus essentially on the entrepreneur or the management team and on the business potential. In FBs they continue to look for strong and capable management teams and businesses with good growth potential or with a good free cash flow.

Several participants did recognize though that a FB proposal often includes a few features that are unacceptable or that add complexity and risk for the VC investor. Participants from two VCFs, for instance, revealed that a factor that makes them reject FB proposals is the family's intention to regain the business ownership at the VCF's exit phase. One VC considered this desire incompatible with the strategy of his VCF, since their goal is to have a controlling stake in all the business they invest. He considered this as the only way they can effectively influence the decision making process and exit their investment via trade sale or initial public offerings.

Another VC considered that the family must be ready to sell all the company out in order to maximize the return potential of the VCF's investments.

Another issue of concern in financing FBs regards the lack of "normal" corporate governance culture and board procedures in FBs, although some participants recognized that this problem also exists in many non FBs, especially in smaller organizations. Moreover, family ownership is perceived having strong influence on the company culture. The strong company culture, despite its advantages may also present disadvantages that even over a considerable period of time are rather difficult to overcome.

*"The family ownership has very much impact on the way the personnel thinks and the way the operation is organized and that is something that you cannot buy away!"*

The emotional and social connection of the family to the business can also increase the complexity of the investment as the business and the family are usually perceived by the VCs as indivisible.

Often a number of family members are involved in the business, yet the overall opinion of the participants was that this situation represents a problem for the VCF only in the cases when the family members do not have the appropriate skills for the job or occupy the post that can significantly hinder the development of the business. Otherwise, most participants said they would not hesitate to invest in an attractive FB even if unnecessary or less-skilled family members would remain on the payroll. In their view this situation can be accepted as a part of the deal. Yet the consequence of maintaining such members would be a reduction in the business valuation to incorporate the extra burden, or then adaptations in remuneration package of the family members would have to be made to discount the cost of such inefficiencies. As one of the VCs exemplifies:

*"It doesn't really matter if you pay the entrepreneur ten thousands a month or if you pay him seven and (his) less capable son three thousands: it all adds up the same!"*

Despite the fact that the family members involved in the business to finance require an extra assessment to avoid inefficiencies, most participants considered that family members do not normally represent a burden for the business. These members are actually viewed as hard workers being strongly committed to the business and having heightened sense of responsibility.

*"...they take the risk very differently! The risk concept is very different than in some other companies where the managing director just can go to any other company if this doesn't succeed."*

## Structuring Family Business Deals

The participants' accounts revealed that the deal structure for investments in FBs may change, especially in cases when it is clear that the family wishes to continue with the business after the exit of the VCF. Participants from those VCF which regard this sort of FB's aspirations as acceptable revealed that financing package would, in fact, be structured differently:

*“The structure of the investment would be different and also what sort of risk we can assume, what sort of other financing the company should be getting, what sort of participation in the financing the family should have and so on. So... the perspective would be very different and of course the position that the company has in our portfolio would also be very different. We wouldn't be expecting so high return on it but, in return, we would have different type of structures or instruments for our investment and also other sort of financing – probably we would look for more loan type of financing from other investors or other banks.”*

The result tends to be financing packages where the proportion of equity is significantly reduced in favour to debt or quasi-equity. Depending on the leverage capacity of the business and desired risk exposure of the parties involved, the debt can be provided by the VCF (subordinated debt/mezzanine) or by other debt providers. In the cases where it is the VCF who provides the debt the deals normally include some equity kickers (warrants or other payment in kind) or some guaranteed minimum return on capital. From the VCFs' point of view this solution reduces the investment risks and aligns the objectives of the FBs with the ones of the VCF. Some participants also consider that this financing alternative fit well the family needs since it enables them to remain in control of (most) of the ownership.

## CONCLUSIONS

Overall the findings suggest that the decision-making criteria of VCs remain unchanged when considering FBs proposals. However, some VCs do identify organizational and cultural specificities in FBs that need special attention. While some of these specificities can present advantages over non-FBs (e.g. high level of commitment), others (e.g. low level of corporate governance) are clearly perceived by VCs as disadvantages. Although the balance between the advantages and disadvantages depends on each particular FB case, the overall perception of VCs is that these specificities tend to create additional risk for the investment. Despite the additional risk involved, most of VCs remain interested in investment proposals from FBs (especially those FBs at the succession/exit phase) regarding them as an important source of deal flow in the near future.

It is at the deal structuring and the exit strategy where most differences in the approach adopted by VCFs toward FBs as compared to non-FBs can be found. While in the case of non-FBs VCFs usually structure deals consisting in a mix of equity and debt instruments and demand exit strategy that includes the possibility for the VCF to force the sell of 100 percent of the business, some VCs revealed openness to structure deals with FBs using instruments that respect the objective of some families to maintain ownership and management control over time. The solution typically consists in deal structures composed mainly of debt financing instruments

(subordinated debt/mezzanine) with some sort of equity kickers or minimum return on capital. This option of deal structuring seems to have advantages for both parties involved: for the FBs it enables maintenance of the ownership structure desired by the family, and for the VCF it reduces the investment risks and aligns the objectives of the FBs with the ones of the VCF.

The findings of this exploratory study suggest that it is important for the VCFs to understand the specificities of the FBs before investing in such form of business organization. For the FB owners it shows that VC is, indeed, an alternative source of financing worth considering, because even in the cases where the family wishes to maintain ownership and management control over time, it is possible to find VCFs interested in adapting deal structure to finance them. Openness with regard to the family objectives and awareness of variations in attitudes and strategies of VCFs toward investments in FBs are important preconditions for successful collaboration between VCFs and FBs.

## ENDNOTES

<sup>1</sup> For the purpose of this study, the definition of VC adopted is the broader one prevalent in Europe, according to which VC includes not only seed and start-up financing, but also later-stage financing, i.e., expansion projects, buyouts, turnaround and mezzanine financing.

<sup>2</sup> The findings presented in Table 2 include both the FBs that were identified by VCs as such at the time of the investment and those that became FBs or were unveiled during the VCF presence in the business.

**THE IMPACT OF THE ENABLING ORGANIZATION ON CUSTOMER  
SATISFACTION: BANKS AND THEIR SMALL BUSINESS CUSTOMERS**

**ABSTRACT**

The primary goal of this paper is to investigate how banks that are structured as enabling organizations are able to generate higher satisfaction among their SME customers. The enabling organization builds on two principles. Firstly, as banks generally survive through standardization of services the enabling organization needs to maintain a competitive inner standardized core of services to be able to generate income in a competitive market. The second principle is based on the organization's capability to create an atmosphere where the bank officers facing the customers will have a degree of competence high enough to guarantee a professional status. The study is based on a sample of 359 SMEs in Sweden. Lisrel, a structural equation modeling technique, is used to analyze the empirical data. Banks, structured as enabling organizations, generate higher satisfaction among their SME customers primary because they are able to generate an atmosphere where the individual bankers are encouraged to be flexible and take own initiative in the interaction process with the customers. What banks do as enabling organizations is that they actually shield their customers from having to interact with the bureaucratic machinery inside the bank. The bureaucracy is still there; it has to be there in order to comply with regulations. The only, but vital, difference is that the customers rarely see the machinery at work. Instead, they are in the hands of a seemingly individualistic officer of the bank who appears to be as flexible as anyone else in their environment.

## INTRODUCTION

Small and medium sized enterprises (SMEs) are argued to be important customers, offering the greatest profit opportunities for banks (Bannock and Doran, 1991; Zineldin, 1995). A recurring theme in the discussion of SME-bank relationships has therefore been focused on the satisfaction of the SMEs (Ennew and Binks, 1996; Jamal and Naser, 2002; Madill et al., 2002). Among other things it is argued that the more satisfied the customers are the more likely they will have repurchase intentions (Armstrong and Boon Seng, 2000) and the higher probability that they will remain as customers. (Bloemer et al., 2002). This means that the loyalty of the SMEs is increased as they become more satisfied and the bank can in turn gain increased profit through the continual purchase of their SME customers. However, it has been indicated in several studies that the SMEs are somewhat dissatisfied with their banking relationship (Harrison, 2001; Butler & Durkin, 1995; Zineldin, 1995).

The bankers are, among other things, criticized for being too focused on selling the bank's products instead of trying to understand the needs and requirements of their SME customers. It has furthermore been argued that bankers are reluctant in creating close relationships with their SME customers that can require personal involvement. The criticisms are often targeted towards the individual bankers involved in the interaction process. However, as has been indicated by other studies, the organizational structure is also of importance and indeed affects the behavior of the individual bankers and in the end also the satisfaction of the customers (Madill et al., 2002). In this paper we use enabling organization as a concept for an organization that creates an atmosphere where the individual employees are encouraged to have a flexible attitude towards the customers and still being able to maintain a competitive inner standardization of services. The purpose of this paper is to evaluate how banks, structured as enabling organization can generate higher satisfaction among their SME customers.

Many of the basic ideas of the article are based on Henry Mintzbergs (1979) classic definitions of organization structure. The terms adhocracy and machine bureaucracy are also used in this article to stress the impact, the organization structure can have on customer satisfaction. The bankers that possess an ad hoc professionalism spend more time with their customers, rather than spending their time navigating through the often-complicated inner life of the bank. The SME customers are thus met by a highly professional advisor in an ad hoc role whose decisions are based on the customers need. In opposite, bankers employing the machine bureaucracy processes tend to subject their customers to standardized treatment. The aim of this article is thus to investigate how in fact the enabling organization functions through the employees ability to ad hoc relate to the customers and how it by avoiding machine bureaucracy processes is able to generate higher customer satisfaction.

The idea of strategic fit between the capabilities of the organization and the characteristics of its environment is at the core of organization management in general, and thus also for banks as organizations (Hall and Saias, 1980; Miles and Snow, 1984; Markides and Williamson, 1996). In particular, by enabling organization we emphasize the importance of shielding the customers from the inner works of the organization, an integral idea in the decentralized bank organization. Perhaps this is the single most important trait in gaining significantly higher satisfaction levels among SMEs. It should be emphasized, however, that even the enabling bank organization combines elements of simplicity and complexity in handling the environment, implying a step from the bureaucratic traditional form of banking to a differentiated organization, rather than a dynamic, virtual organization which would be all but impossible given the requirements of supervisory authorities in the banking industry (Mintzberg 1978, p. 287).

## THEORETICAL POINTS OF DEPARTURE

The measurement and explanation of organizational structure has been a major concern in organization theory (Wong and Birnbaum-More, 1994). One approach argues that the variables can be found internally in the form of size, technology, or dependence (Pondy, 1969; Pugh, Hickson and Hinings, 1969<sup>1</sup>; Blau, 1970). A second approach that emerged during the late 1960's tried, in addition, to find variables outside the organization in the specific environment (Thompson, 1967; Lawrence and Lorsch, 1967). The determinants of organizational structure have in the latter approach been connected, among other things, with environmental uncertainty as the key predictor (Miller and Dröge, 1986; Greenwood and Hinings, 1988; Wong and Birnbaum-More, 1994). Organizations handle uncertainty through internal strategies of adaptation, adjustment or organizational design, and through external strategies or modes of interaction. The general proposition is that the complexity of the environment is reflected in the complexity of the organizations' structure, or the number and variety of units.

In the case of the banking industry, the banks are embedded in a larger societal context (Emery and Trist, 1965; Pfeffer and Salancik, 1978) that fundamentally shapes their structure. In this, banks are almost at the mercy of environmental determinism (Dastmalchian, 1986; Davis and Powell, 1992), in that banks are shaped by supervisory authorities with few opportunities to themselves shape their regulatory context<sup>2</sup>. The supervising authorities in charge of banks tend to emphasize stability in the banking industry for good reasons. Over time the banks have more and more been shaped in a traditional mode where centralization, formalization and standardization have remained keywords in the industry. The traditional bank has been authority-bound and built on principles of hierarchy and bureaucracy. The

---

<sup>1</sup> The Aston school

overwhelming rationality mode in such an organization tends to be cost-efficiency, as banks are bound by economy-of-scale. As a result, the banks as organizations have typically been seen as monolithic rule-bound organizations that in essence functions in the form of the machine bureaucracy. Meyer and Rowan's (1977, p. 341) almost deterministic view on how external obligations come to take on virtually rule-like status within organizations are apt descriptions of the banking industry.

The individual bankers are taught to comply strictly with the rules, as there are virtually no incentives for bankers to behave flexible and show innovativeness in solving problems at work. Instead bankers generally are conservative in their approach to new dilemmas, and rarely deviate from safe procedures. Bankers well exemplify institutions guided by taken-for-granted assumptions on how things are to be done (Scott, 1987). In addition, the way things are to be done in the banking industry is spread throughout different banks creating a highly institutionalized environment<sup>3</sup>. In a study of 165 savings and loans organizations Haveman (1993) used DiMaggio and Powell's (1983) ideas of institutionalism to prove that banks to a high degree mimic each other's organizations and behaviors. The way bankers conduct their business is transferred to the customers. Thus, customers meet bankers who will stick by their regulations no matter what. Some customers are content with what they receive and actually do not have any real incentives themselves to interact closely with their bank. Customers who, however, have pressing matters that need to be resolved promptly in a flexible manner often face difficulties in interacting with their bankers. To them, bankers only care about formality and disregard that the customer is an individual being seeking an individual solution. In effect, the bank transmits their bureaucratic way of doing business to their customers, whether they like it or not.

---

<sup>2</sup> This can of course be discussed, as banks tend to work behind the scenes to influence policy-makers.

<sup>3</sup> Akin to institutionalism as described by DiMaggio and Powell 1991

In an attempt to challenge the set up of traditional banks there are a small number of banks abiding to another basic principle. These banks function exactly in the same bureaucratic sense as all the other banks, but they chose to interact with their customers in a different way. The Swedish bank, Handelsbanken is an example that has for a long time worked under a strict regimen of decentralization that has in many ways been the opposite of the way traditional banks function<sup>4</sup>. The decentralized system has, from time to time, clashed with the interests of supervisory authorities, but in particular the system's way of surviving crisis has continued to interest and amaze onlookers. And yet, the system has not been copied very often. The reason, according to an interview made by the authors, is that centralized management in most banks fears the consequences of losing control of operations, both in terms of decreased power and in terms of the consequences of failure.

Handelsbanken, with its decentralized structure can be seen as an enabling organization, as decentralization is more a case of enabling subordinates than anything else. The enabling organization is based on a number of mechanisms. Based on the aforementioned argument of how traditional banks function the enabling organization is inherently based on local initiative and flexibility. Anything goes as long as the banks earn enough money, given compliance with basic banking rules. The range of decision-making is extensive and the purpose of the decision-making system is in promoting own initiative. The bank places less reliance on computerized systems than its counterparts, and the decision-making system is less formal. The integration devices are, in order of importance: (1) policies, (2) procedures and (3) rules. Meaning that the integration devices leaving more room for maneuver are the most important.

---

<sup>4</sup> This description is build on personal interviews with Jan Wallander (Silver, 2001), former CEO and chairman of Handelsbanken in Sweden, on books written by him (1991; 1998) and also on an extensive interviews with staff of the same bank and their competitors (Silver 2001).

## **The Enabling Organization**

The enabling organization builds on two principles. Firstly, as banks generally survive through standardization of services (Silver, 2001) the enabling organization needs to maintain a competitive inner standardized core of services able to generate income in a competitive market. The enabling organization strives to push decision-making as closely as possible towards the bankers facing the customer. As a result, the organization manages to achieve cost reduction through minimizing and computerizing administration as well as headquarters and regional management and personnel. Within the organization the amount of interaction is minimized. This will also mean that innovativeness in terms of enhancing processes may be reduced, as the organizations in charge of development are reduced to a skeleton crew size. However, banking is known for blueprint copying, which means that not every innovation needs to be made within the organization.

The second principle of the enabling organization is the capability of the organization to create an atmosphere where the individual bankers facing the customers will have a degree of competence high enough to assure a professional status. Not only will the bankers need to know the inner standardization system intimately, they also need to be able to show some innovativeness and independence in facing the customers (Donnelly, 1994). The enabling organization needs to maintain an organization where a flexible attitude is encouraged. In doing so the enhancing organization maintains an organization based on few, but clear and concise measurements of success. In effect, the organization refrains from signaling preferable ways of action through the use of incentives closely connected to particular conditions, for instance incentives for selling certain products. Instead the enabling organization uses standardized measurement objectives that encourage the local bankers to apply whatever action is deemed applicable to reach those targets. For instance in the use of a

cost/income ratio where it is up to local management to do whatever they feel is most appropriate to reduce costs and increase revenues in their particular environment. The emphasis on easily measured, simple, challenging but obtainable short-term targets is an old idea in banking (Coult 1990, p. 115), but few banks manage to scale them down to one single ratio.

While taking the above-mentioned principles into consideration, two hypotheses are created. Firstly we hypothesize the enabling organization to be positively correlated to the formation of ad hoc professionalism among the bankers actively engaged in the bank-customer interactions. Secondly, we hypothesize the enabling organization to be negatively correlated to the use of machine bureaucracy processes in the bank-customer interactions.

**H 1:** The enabling organization affects the degree of ad hoc professionalism among the individual bankers actively engaged in the bank-customers interactions positively.

**H 2:** The enabling organization affects the use of machine bureaucracy processes in the bank-customers interactions negatively.

### **Ad hoc Professionalism**

The crucial part in determining the success of the interaction between the bank and the customer is in the capability of the individual banker in the actual engagement with the customer. Strategy, organizational structure, structure of internal information systems and activities are all-important determinants for the ability of co-workers to enact in their immediate environment (Grønhaug & Falkenberg 1989; Gioia and Thomas 1996; Weick 1996). The average banker is closely attached to the inner values of the banking system as

most bankers start at a young age at the bank and slowly advance internally before they are provided with a platform for engaging in crucial bank-customer interaction episodes. It is therefore imperative for the enabling organization to educate and internally promote bankers to maintain an individualistic streak within the large bureaucratic machine.

It could be argued that just as the traditional bank instills values in which actors within the bank imitate each other, the enabling organization also instills values where actors imitate each other through taken for granted assumptions (Ritti and Silver 1986; Davis and Powell 1992; Haunschild and Meyer 1997). Even in the training organization the imitation is provided through learning by observation and thus institutionalizing behavior (Whitley 1987). However, the vital difference is that in the enabling organization the individual worker witness the ad hoc role of other co-workers and their initiative and skills. The provision of an incentive system is the most important variable in determining the degree of independence among bankers. Other variables include the interaction between bank officers in charge of bank-customer interactions and their superiors as well as the interaction between bank officers in charge of bank-customer interactions and various specialists in the bank. The individual will if all of these variables are handled be able to possess an ad hoc professionalism where the customer recognizes the bankers as a highly professional advisor in an ad hoc role, both able to and willing to guide the customers through the intricacies of financial decision-making.

The ad hoc professionalism spends more time discussing with their customers and thereby will learn how to interact with them, rather than spending their time navigating through the often complicated inner life of a major bank bureaucracy. Thus, for the individual banker the daily life is more about learning how to interact with the customers, in particular in learning how to listen to the customers. The ad hoc professionalism fostered among bankers result therefore in increasing time spent with the customers and actually listening to whatever

happens in their daily life. This will make it easier for the individual bankers to identify the needs of their customers. With a more accurate picture the bankers can thus deliver services better match to the customers' needs (Ennew and Binks, 1996). As the ad hoc professionalism never pushes individual products, it is more a case of where the banker listens and tries to pinpoint what to sell to this individual customer, than to wait for the opportunity to force sale the product of the day. The bankers will be judged by their ability to provide advice based on what they gather from listening to their customers and in aiding customers as they present particular problems for the banker (Zineldin, 1995). The increased frequency of contacts between the banker and the customer is argued to improve the working relationship between the two, which in turn leads to higher customer satisfaction (Gammie, 1995). We therefore hypothesize that a higher degree of ad hoc professionalism among bankers engaged in the bank-customer interactions will be positively correlated to customer satisfaction.

**H 3:** The customer satisfaction is increased by the higher degree of ad hoc professionalism among bankers engaged in the bank-customer interactions.

### **Machine bureaucracy processes**

A clear indication of the machine bureaucracy processes being forced upon the customers is when the customers are subjected to standardized treatment by the bank. Standardized treatment of customers is partly a result of increased computerization (Chorafas and Steinman 1988, p. 1) and partly due to new entrants in the market relying on standardization (Baumohl 1993). Most SME customers will when they approach the bank for advice in important matters demand that the bank treats their problem as unique in a unique environment. Or at least have the feeling that they are seen as unique. Many will however be dismayed to find out

that they are being subjected to the latest promotion campaign within the bank. It is usually the case of the “new, innovative product” that will be available for the customer, and that this product just happens to be the permanent solution to this particular problem.

Another clear indication of machine bureaucracy processes is when the decisions of the individual bankers mainly are based on the customers’ availability of collateral. The fear of bankers in taking individual initiative is the way that they rather claim that a loan application will be turned down due to a lack of collateral than due to a lack of ability to repay a loan from an operating business. Collateral has been seen as a promising way of computerizing data for credit risk purposes (Clementz 1986, p. 17). As soon as the discussion is based on collateral, however, something is usually amiss in the actual loan application. In theory, the banker should always strive to first and foremost concentrate on the business operation, and not on the collateral available. Especially on cash flow as a decision making criteria (Goldberg 1992). Bankers tend to use the collateral as a way to avoid an argument with the customer about the potential of the business. This is, of course, not a very practical course of action in the enabling organization. Since the use of machine bureaucracy processes leads to a more standardized treatment of the customers, the needs of the customers tend to be put as a second priority. In fact, the major criticism of the banks has been targeted towards their focus on selling standardized products and on their lack of understanding of the customers’ needs and requirements (Harrison, 2001). With this we hypothesize that the use of machine bureaucracy processes in bank-customer interactions is negatively correlated to the level of customers satisfaction.

**H 4:** The customer satisfaction is decreased by the use of machine bureaucracy processes in the bank-customer interactions.

## HYPOTHESIZED CAUSAL MODEL

Hypotheses 1-4 are combined into a structural model (see fig. 1), illustrating the relationship between the different variables. As shown in the figure, the enabling organization is believed to have a positive effect on the used of ad hoc professionalism among the bankers that meet the customers (H 1). Furthermore, banks as enabling organizations are believed to have lesser degree of machine bureaucracy processes within the organization (H 2). The end variable, customer satisfaction, is supposed to be affected by the use of ad hoc professionalism as well as the degree of machine bureaucracy processes among the bankers facing the customers. However, as illustrated in the model, the customer satisfaction is positively affected by the degree of ad hoc professionalism (H 3) while it is negatively affected by the degree of machine bureaucracy processes (H 4). The model can be seen as an additional hypothesis, since it correlates all four hypotheses into one. For example, although we have not stated any correlation between the enabling organization and the level of customer satisfaction, there is a relation, not directly but indirectly. The enabling organization has an effect on the customer satisfaction positively through the ad hoc professionalism. Likewise, the enabling organization is believed to affect the customer satisfaction through the use of machine bureaucracy processes. The relation is however hypothesized to be negative.

## DATA AND METHOD

Data used for the empirical analysis were obtained from a survey sent to SMEs in Sweden. A total of 1131 questionnaires were randomly distributed to those SMEs with 200 or fewer employees. The random sampling of the firms was made by the statistic Sweden. Thus, in this paper SMEs is defined as firms that have 200 or fewer employees and also they should not be part of a corporate group. This definition is usually used in earlier research in Sweden regarding SMEs (Davidsson, 1989; Cressy and Olofsson, 1997) and it is also compatible with the one put forward by Bolton (1971).

The survey was formulated and sent out in December of 2003 to CEOs of the firms. After one month a follow-up reminder was sent out to those that had not yet answered. Of the 1131 questionnaires sent out, 359 were returned, giving a response rate of 31,8 percent. The survey conducted was focused on SMEs financial needs and relation to their financiers. Since earlier research has concluded banks as the most important actors SMEs encounter in their search for external capital (Berggren, 2002), a specific part about SMEs banking relationship was therefore included in the survey. In line with earlier research it was also confirmed by the answers that the majority of SMEs in Sweden are finance by banks. Of those firms that answered the questionnaires, banks financed 69.9 percent. A large amount of information could therefore be collected about SMEs and their banks. The bank as organization and the behavior of the individual bankers involved in the interaction process could consequently be portrayed from the eyes of the SMEs by the answers collected. Since the study is to investigate how the satisfaction of SMEs is affected, it seems reasonable to do the study from the perspective of the SMEs.

Due to the relatively large number of non-respondents a dropout analysis was conducted. A comparison between those that have answered the questionnaires with those that

have not answered was conducted to check bias. This was done using key statistic such as size, industry and age. No such bias could however be found.

## **Lisrel**

Lisrel, a structural equation modelling technique (Bollen, 1988; Jöreskog & Sörbom, 1993; Jaccard and Wan, 1996) was used to analyze the empirical data collected. Lisrel structural models are derived into two-step procedures. First, higher-order variables are created, called latent variables or constructs. These variables capture the underlying commonalities of the indicators (Bollen and Long, 1993). The second step constitute of creating a model by linking the constructs in a causal chain (Jöreskog and Sörbom, 1993).

Also the validity of the structural model is assessed in a two-step procedure using three key validity dimensions. These three dimensions are 1) convergent validity, which checks the homogeneity of the indicators and their constructs, 2) discriminant validity, which refers to the extent of separation between the constructs and 3) nomological validity, which checks the validity of the entire model and indicates the fit between the model and the data. The three key dimensions are first used to test the measurement model without causal relationship between the constructs. Thus, the measurement model is tested to see if the chosen indicators for a construct do really measure that construct. When the validity of the measurement model is established the same key dimensions are used in the second step, testing the structural model with causal relation between the constructs.

A number of statistical values can be used in the validity process. In accessing the convergent validity three estimates can be used; coefficient, t-value and  $R^2$ -value (Jöreskog and Sörbom, 1993). Same statistical values can be used when testing the separateness of the constructs. The strength of the relationship between different variables is

presented by the coefficients (Bollen, 1989). There are no definite limits for the coefficient instead the value should be judged in association with the theoretical considerations. The t-value estimates the statistical significance and should be equal or exceed 1.96 to be statistically significant at the 5 percent level. The  $R^2$ -value estimates the linear relationship between two variables. It is preferable to have  $R^2$  above 0.20.

Nomological validity is assessed by using measures as  $\chi^2$  - value, degree of freedom and a probability value.  $\chi^2$  - value and degree of freedom measures the distance between the data and the model while the probability value is a test of a non-significant distance between the data and the model. There are no definite threshold values for the  $\chi^2$  and the degree of freedom measure (Jöreskog and Sörbom, 1993) but some authors have concluded that the fit is good when the two measures are approximately the same. The probability estimate, the p-value of the model must be higher than 0.05 to be valid at the 5 percent level. Comparative Fit Index (CFI), which checks for non-normal distributions, and Goodness of Fit Index (GFI), which checks for sample size effect, are two other frequently used measures of nomological validity. CFI as well GFI should be above 0.90. Another measure worth mentioning is RMSEA, which measures population discrepancy per degree of freedom and should be below 0.08. However, as pointed out by Jöreskog and Sörbom (1993), all the other measures of nomological validity are functions of  $\chi^2$  - value.

### **Construct Validity**

By assessing the measurement model the validity of the constructs is tested. The validity of the measurement model is verified, nomologically, discriminately and convergently. Nomologically the measurement model is verified since the  $\chi^2$  - value is 10.50, with 9 degrees of freedom, at a probability of 0.31. The probability value high over the rule of thumb and the

fit between the data and the model is valid since the  $\chi^2$  - value and the degrees of freedom are approximately the same. Also measures as CFI, GFI and RMSEA support the validity of the entire model (1.00; 0.99; 0.022). The separateness of the different constructs within the model is obvious, securing the discriminant validity. The t-value and  $R^2$  - value are used as measures to test if the chosen indicators really measure the constructs created. Also, the relations between the constructs and the indicators are judged in association with the theory. The indicators and their respective constructs are displayed in *Table 1*. Since there is little difference between the figures in the measurement model and the structural model, we have chosen to present the figures from the structural model, when analyzing the convergent validity. This is mainly done because of pedagogical reasons. As can be seen at *Table 1.*, the dependent variables are standardized; so one of the indicators of each constructs do not have t-value presented.

Enabling Organization is assessed in an organizational level and is measured by using two indicators. The first indicator concerns the first principle of the enabling organization, which is the organization need of maintaining a competitive inner standardized core of services. The question whether the bank provides financing for SMEs at reasonable conditions portrays the respondents' perceptions regarding whether the bank has competitive prices or not. The second principle of the enabling organization is assessed by the question whether the bank is good in solving the SMEs financial problem. With other words, it measures whether the bankers facing the customers have the competence needed to be able to solve their customers' financial problem. The key statistical values in *Table 1.*, shows good convergent validity of the construct. Both indicators have  $R^2$  - values (0.64; 0.75) and t-values (17.06; 19.05) well above the rule of thumb.

The Ad hoc Professionalism construct assesses the individual bank manager's, engaged in the bank-customer interactions, flexibility and adaptability to the need of the

customers. As has been argued by Zineldin (1995), “*bank management’s persuasive action must be geared to the client’s needs*” and not according to the inner life of the bank. Earlier research indicates that SMEs would like their banking relationship to include more than financial transaction. They would like their banking relationship to be based on a more personal level (O’Donnell et al., 2002) including advice and support (Butler and Durkin, 1995) from an individual bank manager. The respondents’ answers to the questions regarding, whether the bank is good in giving (1) advice and (2) support in times of trouble, indicate if they perceive the banker facing them to be flexible and adaptive to their needs. The indicators’  $R^2$  and t-value show that they are well related to the construct, securing the convergent validity. The  $R^2$  values are 0.61 respective 0.83, well above 0.20. Also the t-value of on of the indicators is well above the rule of thumb, 16.40.

Machine Bureaucracy is measured by two indicators, which both secure the convergent validity. The  $R^2$  values above 0.20 (0.25; 0.46) and the t-value well above 1.96 (6.80). The two indicators stress dimensions that have been questioned by SMEs for a long time. The collateral requirements for a bank loan have been argued to be unfair and not particularly situated to the business of the SMEs, instead collateral is required according to the bank’s rule and policy. The collateral requirements have indeed led to a borrowing constraint among the SMEs (Cowling and Westhead, 1996). The second dimension concerns the bank’s focus on selling products. The bankers’ focus in selling the bank’s products has been argued to put the needs of the customers as a second priority (Harrison, 2001). The questions whether the SMEs find their bank to be too focus on the (1) collateral and on (2) selling products, give us answer whether the SME customers are subjected to standardized treatment by the bank.

The Customer Satisfaction is measured explicitly by a question, whereby the SMEs are asked to answer how satisfied they are with their banking relationship. This

construct is based on the customer's perceived satisfaction. The error variance of the indicator is set to zero. The factor loading and the  $R^2$  value are thereby equal to 1.00.

-----  
Insert Table 1 here  
-----

## RESULTS

As presented in *Fig. 2*, the nomological validity of the structural model is secured. The  $\chi^2$  value is 14.86 with 11 degrees of freedom, at a probability of 0.19. This means that the entire model holds together and the fit between the model and the data is good. This is also confirmed by other measures as CFI, GFI and RMSEA (1.00; 0.99; 0.031). The separateness of the constructs is shown to be acceptable, since the modification indices of the structural model did not suggest any changes. All  $R^2$  values are above 0.20 and all t-values are well above 1.96, securing the discriminant- and the convergent validity.

The results of the statistical analysis indicate that there is a positive relation between the enabling organization and the extent of ad hoc professionalism among the bankers that are actively engaged in the customer interactions. Hypothesis 1 is consequently supported, with a coefficient of 0.84. Hypothesis 2, with a coefficient of  $-0.74$  between the constructs, is also supported, showing that there is a negative relation between the enabling organization and the existence of machine bureaucracy processes in the bank-customer interaction. The result also indicates that the perceived satisfaction of the SME customers is increased by ad hoc professionalism among the bankers facing the customers, supporting the hypothesis 3 (0.38). The last hypothesis is also supported with a coefficient of  $-0.33$ , which

indicate that the use of machine bureaucracy processes in the bank-customer interaction negatively affects the perceive satisfaction of the SME customers. This means that the enabling organization generate higher satisfaction among their SME customers by creating an atmosphere that increase the ad hoc professionalism among the individual bankers and by decreasing the use of machine bureaucracy processes. The individual banker is given incentive to work flexible according to the need of the SMEs. The SME customers are thus not treated by standardized solutions by the enabling organization; instead they interact with an individual banker, who gives them individual solutions to their problems.

## **DISCUSSION**

The results of the study indicate why the enabling organization is able to generate higher customer satisfaction. Apparently this type of organization manages to create an atmosphere in the relationship, which cannot be easily matched by their more standardized counterparts. One of the most striking features of the enabling organization is that, inside it is still a highly standardized and computerized bureaucratic machine. Due to reasons of economy-of-scale and due to demands from supervisory authorities, there is still a need for the enabling organization to maintain a highly standardized format. What the organization does not have to do, however, is to show those inner workings to the customers.

In the enabling organization mode the bank chooses what to display to their customers, and knowing that most customers prefer not to interact with machinery in more

delicate and pressing matters, they choose not to display the machinery. The customer may still have to fill in a form or two, but the banker never tells the customer that they will have to await the decision of some unseen decision-makers deeply within the organization. The banker will furthermore never argue that the reason for why a credit cannot be extended is due to regulations, when in fact the reason is that the bankers fail to trust the capability to repay the loan. The banker will never routinely sell standardized solutions to the customers merely because some marketing manager in a head office thousands of miles away has implemented a new sales scheme. Instead, the banker will in every way take personal responsibility for whatever happens to the customer and whatever decisions are being made within the organization.

This means that one of the most significant dimensions of the enabling organization is the ambition to hide some of the inner processes of the bank from the customers. Some may say that in that case the organization cannot really be very enabling after all. In fact, however, based on the 50 or so interviews with bankers and some 60 more interviews with customers, mainly SMEs, the enabling organization really shows its strength as a decentralized organization. Other quantitative material (Silver 2001 for example), show that the decentralized bank significantly differs from its more traditional competitors in the bank industry in terms of control mechanisms.

## **MANAGEMENT IMPLICATIONS**

Banks organized as enabling organizations can create advantages not only for the banks but also for the SMEs. From the perspective of the banks it has been repeatedly confirmed by studies in customer satisfaction<sup>5</sup> that decentralized banks are higher rated than their

---

<sup>5</sup> In Sweden called "Svenskt Kvalitetsindex" and is conducted as a national survey by researchers at the Stockholm School of Economics.

counterparts. In addition, the decentralized banks present a higher net return on equity than their counterparts. The only significant drawback appears to be the rigor by which this kind of bank organization is set up. The enabling organization needs to be firmly institutionalized in the very minds of the co-workers. Management needs to avoid interfering with subordinates or alternating the system, in order for subordinates to maintain their attention on the customer. At the same time, the professional banker needs to be better educated, as they cannot rely on set rules. If these criteria are met the bank can become as successful as Handelsbanken.

As has been indicated before, SMEs do not want a relationship with a bank organization, what they want is a relationship with an individual bank managers, who they can trust and turn to in times of problems and who is flexible enough to give them individual adaptive solutions. All SMEs are unique and so are also their financial needs. It is therefore important that the individual banker, interacting with the SMEs, are encouraged to adopt a flexible attitude towards the customers and are competent enough to solve the problems of the SMEs. In this study it has been confirmed that the enabling organization is able to create that kind of atmosphere that allow the individual bankers to be flexible and adaptive to the needs of the SMEs. From the perspective of the SMEs, the enabling organization means that they do not need to interact with the bureaucratic machinery inside the bank, instead they will be at the hands of a seemingly individualistic bank officer who appears to be as flexible as anyone else in their environment. The SMEs will be met by an individual bank officer who will work according to their needs and not according to the bank's need of selling products.

## **KEYWORDS**

Social enterprise; evidence base; policy

## **ABSTRACT**

The aim of this paper is to contribute to current debates about the role of social enterprise and social entrepreneurship in local development. Whilst currently attracting considerable attention from policy makers in the UK, the evidence base for this is limited. Key issues include a lack of

clarity in policy debates about what constitutes social enterprise and associated concepts of social entrepreneurship; the rationale for public policy in this field; and what can/should be done to foster their development. This paper seeks to address these issues, drawing on a number of recent studies in which the authors have been involved, which includes the co-ordination of a national baseline mapping exercise, on behalf of a UK government department

The paper includes a short empirically-based section, in order to demonstrate the nature and extent of the contribution of social enterprises to local development and how this may be assessed. This part of the paper draws mainly on a study of the contribution and impact of social enterprise to rural economies and communities. Focused on Devon and using a case study-based approach. This study is of wider interest because of the methodology developed to assess a wide range of social and economic impacts that social enterprises are claimed to contribute. As a consequence, the paper seeks to contribute a greater degree of conceptual clarity to current policy debates, as well as some of the practical issues that need to be addressed if the contribution of social enterprise in practice is to be better understood.

## **1. Introduction**

The aim of this paper is to contribute to current debates about the role of social enterprise and social entrepreneurship to local development, focusing particularly on issues related to the development of the evidence base in the UK. More specifically, the paper seeks to make a conceptual contribution, as well as discussing some of the practical issues that need to be addressed if the contribution of social enterprise in practice is to be better understood. Whilst

currently attracting considerable attention from policy makers in the UK, there is a lack of clarity and agreement about firstly, what constitutes social enterprise; secondly, the nature and extent of their contribution to economic and social development; and thirdly, what should be done to foster their development. As a consequence, one of the current policy priorities in the UK is to improve the evidence base of the social enterprise sector.

Current policy interest in social enterprise in the UK was initially associated with the Labour Government's concern to tackle social exclusion through a focus on neighbourhood renewal. This was reflected in the National Strategy for Neighbourhood Renewal (Cabinet Office, 2001) and the reports of the Treasury's 18 Policy Action Teams (PATs). Of these, the recommendations emerging from PAT 3 report on 'Enterprise and Social Exclusion' (HM Treasury, 1999) are of particular interest, since Government adopted them for inclusion in its plan for action.

Recommendations relevant to social enterprises included:

- Recognition of social enterprises as a group of businesses deserving support.
- A commitment to enhancing the potential of social enterprises.
- A commitment to recognising social enterprises in national funding criteria.
- A commitment to shifting the culture of social enterprises and the voluntary sector away from grants and towards loans.

The PAT 3 report was followed by the DTI's 'Strategy for Success' (DTI, 2002), which sets out the current policy approach of government, with a strong emphasis on trading social enterprises. This has been described as close to the 'not-for-profits' approach with which social enterprise is

strongly associated in the US and strongly linked to a market-driven ethos (Peter Lloyd Associates, 2003).

The initial focus on neighbourhood renewal in the UK has resulted in much of the attention being focused on the most deprived local authorities, which are predominantly urban. This is because of the more dispersed nature of deprivation in rural areas and the tendency for pockets of low incomes within rural local authorities to be masked by high income groups because of an 'evening out' effect. Nevertheless, the potential contribution of social enterprise to rural development has been recognised at a policy level as part of the current strategy for economic and social regeneration of rural areas (DEFRA, 2004), although there are few policy measures specifically targeted at social enterprises in a rural context. Whilst there are schemes, such as DEFRA's<sup>1</sup> Rural Enterprise Scheme, which are open to both private sector and social enterprises, the level of take up by the latter group has been modest. The Countryside Agency's grants for schemes such as community transport, community renewables, 'vital villages' has benefited some social enterprises.

The emphasis on social inclusion, in which social enterprise is seen as one of the ways of fostering inclusion through the development of enterprising communities and localities has also been promoted in European policies over the last decade. A 'social economy unit' was set up in the early 1990s by DG XXIII of the European Commission, which, more recently, has officially recognised a consultative committee on co-operatives, mutual societies, associations and foundations (i.e. much of the voluntary sector), which are described as 'social economy enterprises'. In addition, the EC's Green Paper on entrepreneurship includes 'social economy

enterprises', or 'non-profit-driven enterprises' among the applications of entrepreneurship referred to (Commission of the European Communities, 2003, p6). It also refers to the role of entrepreneurship in the "efficient delivery of health, education and welfare services (p8), with social economy enterprises 'encouraging the participation of stakeholders in the delivery of such services. Such an approach can supplement public resources and extend the range of services offered to consumers'.

As Amin et al (2002) point out, there are considerable international differences in the way that social enterprises are considered, reflecting differences welfare systems, as well as different political and institutional contexts. For example, in the US, the absence of a strong welfare state is reflected in a well-established tradition of bottom-up community development. In Western Europe, by contrast, the state has tended to take a more prominent role in encouraging and supporting local development, although the contraction of the welfare state in recent years, in some countries (such as the UK), has given a boost to expanding the role of the social economy.

However, one of the current problems is that there is a lack of data concerning the nature and extent of social enterprise activity and its contribution to social and economic development.

Although central government, most Regional Development Agencies (RDAs) and social enterprise organisations recognise the need to improve the current evidence base, achieving it is not an easy task. A number of RDAs and devolved administrations (i.e. in Scotland and Wales) have undertaken some form of mapping exercise as a starting point for future policy development, but there is a lack of harmonisation between these studies concerning the definitions used and also the methodologies employed.

---

<sup>1</sup> Department for Environment, Food and Rural Affairs

The lack of a comprehensive and consistent evidence base led the DTI to initiate a national baseline mapping exercise in 2004 to provide a starting point for building up an evidence base to support the on-going development of the social enterprise sector. This was preceded by the development of guidance on mapping social enterprise in 2003, which is summarised in a booklet of guidance notes, providing some benchmarks for definitions, mapping and evidence collection (DTI, 2004). The authors' experience in applying this guidance in the initial stages of the mapping exercise raised a number of practical issues, drawing attention not just to the heterogeneity of the sector but also to the variety of views among practitioners about what should be included within the social enterprise sector.

## **2. Some Definitional and Conceptual Issues**

There is no universally accepted definition of terms such as social entrepreneurship, social enterprise and the social economy, which means they are sometimes rather loosely used and often defined in different ways by different organisations for different purposes. For example, describing social enterprises, as a new concept, which they suggest, has not yet been widely institutionalised in its member countries, the OECD (1999) has defined social enterprise as:

*“any private activity conducted in the public interest, organised with an entrepreneurial strategy but whose main purpose is not the maximisation of profit but rather the attainment of certain economic and social and which has a capacity to bring innovative solutions to the problems of social exclusion and unemployment” (OECD, 1999, p10).*

The OECD definition is based on a fairly broad view of the social economy, similar to that included in the H.M Treasury's PAT 3 report in the UK, which describes the social economy as composed of:

*“organisations that are independent from the state and provide services, goods, trade for a social purpose and are non-profit distributing” (HM Treasury, 1999).*

In addition, the former Department of Environment, Transport and the Regions (DETR), who sponsored various initiatives concerned with social enterprises since the 1980s stated:

*“sometimes known as social enterprise, a community enterprise is owned and run by local people. It serves the interest of the local community rather than generating private gain, tackling social and environmental issues, providing work, training opportunities and local services. Any financial surplus is used for community benefit, not distributed as private profit” (DETR, 2000<sup>2</sup>).*

This definition uses the term social enterprise as synonymous with community enterprises, which represents just one of a wide variety of types of organisation that may be considered part of the sector, such as worker co-operatives, consumer/retail co-operatives, housing co-operatives and housing associations, agricultural co-operatives, employee owned businesses, development trusts, community foundations, social firms, intermediate labour market projects, credit unions, community loan funds, friendly societies, mutual insurers, building societies and the trading arms

---

<sup>2</sup> In the SRB Round 6 bidding glossary:

of charities (Smallbone et al, 2001). Although ‘community’ can also mean an interest-based community, a geographical focus is more usually implicit in the use of the term, at least in terms of the spatial boundedness of the benefits. Another issue raised in the DETR definition concerns ownership, which has been a key element historically in the UK because of the tradition of co-operatives in the social economy. This is explicitly recognised in some definitions, which emphasise co-operative organisational and decision making structures, alongside ‘not-for-profit’ objectives, whilst also including the trading element (e.g. Birkhoelzer et al, 1997).

The definition currently used by the UK Government is taken from the ‘Social Enterprise: Strategy for Success’ document:

*“A social enterprise is a business with primarily social objectives, whose surpluses are principally reinvested for that purpose in the business or in the community, rather than being driven by the need to maximise profits for shareholders” (DTI, 2002).*

The lack of a widely accepted definition contributes to the difficulties of obtaining statistical and other data about social enterprises, both nationally and internationally. The issue is complicated by the fact that although the level of policy interest may have increased recently, as a response to dealing with social needs that are not met either by the market or by the welfare state, the concept of social economy has a much longer tradition. The result is that contemporary use of terms such as social enterprise and social economy include different types of organisation, which may share a commitment to social purpose but may differ in their traditions, starting points and emphases. A key feature of the contemporary social economy is the inclusion of some participants in the sector that are driven by an ideological commitment to democratic ownership and control and/or

community empowerment, alongside others who are simply seeking pragmatic solutions to emerging gaps within a market-based welfare state. These may be focused on socially disadvantaged groups, but are not necessarily confined to them. Another potential role is with respect to building social capital through interpersonal networks and collective engagement (Putnam, 1993).

Social entrepreneurship has its origins in the 18<sup>th</sup> and 19<sup>th</sup> centuries, when philanthropic business owners, such as Robert Owen, demonstrated a concern for the welfare of their employees by seeking to improve their lives, both in the workplace and in other respects (Shaw and Carter, 2004). More recently, the term has emerged as a label to describe people who ‘create social value (through entrepreneurship) in the non-profit, private and public sectors, which is part of the definition used by the social enterprise initiative at Harvard Business School ([www.hbs.edu/socialenterprise](http://www.hbs.edu/socialenterprise)).

The Harvard definition explicitly refers to the leadership role of its graduates, whether this is as managers of social enterprises, board members of not-for-profits organisations, or as corporate leaders engaging their businesses in social purpose activities. The approach explicitly encompasses the contribution that an individual or organisation can make towards social improvement, regardless of the legal form of the organisations in which they are operating, claiming to challenge the traditional dichotomy between the not-for-profits and corporate sectors. Whilst such an approach may be an appropriate and innovative one as far as education and training for (potential) entrepreneurs and managers is concerned, it mixes social enterprise activity and corporate social responsibility, which is not helpful in a policy context. Whereas social enterprises are organisations whose primary purpose is social, corporate social

responsibility is practised by privately owned enterprises, whose main raison d'être is the generation of profits for their shareholders.

A number of writers have compared social entrepreneurs with their private sector equivalents. For example, Leadbetter (1997) has suggested that many of the characteristics and behavioural traits of social entrepreneurs mirror those of entrepreneurs working in the 'for profits' sector. These include drive, determination, ambition, charisma, leadership, and an ability to inspire others and to make the best use of scarce resources. In an empirical investigation, based on 80 in-depth interviews with individuals involved in entrepreneurship for social rather than personal financial gain, Shaw et al (2002) found a number of similarities with private entrepreneurs, such as a high level of both serial and portfolio involvement in entrepreneurial activity; an emphasis on vision, passion, and creativity; the ability to engage others in their vision and ability to network.

More detailed analysis of the same dataset drew attention to certain differences between the two groups, of which perhaps the most important concerned the nature and extent of exposure to risk. Since social 'entrepreneurs' rarely invest or risk personal finance in their ventures, the nature of any personal risk for them focuses on their personal credibility and reputation, rather than involving financial risk (Shaw and Carter, 2004). It was also concluded that whilst both social and private entrepreneurship requires creativity and innovation, 'in the social context, this is manifested mainly in managerial actions by applying novel solutions to intractable social problems (Shaw and Carter, op cit).

So can such individuals operating in a social enterprise context be legitimately considered to be entrepreneurs? The reference by Shaw and Carter to the nature of personal risk for individuals

involved in developing social enterprise, together with the reference to managerial actions is relevant in this regard. At the same time, it must be recognised that there is spectrum of views concerning definitions of entrepreneurship expressed in the mainstream entrepreneurship literature, with entrepreneurs ascribed different roles by different theorists. These include the risk-bearing, uncertainty roles emphasised by Knight (1921), which the leaders of social enterprises are unlikely to perform, and the innovator role of Schumpeter (1934), which only a minority may be able to achieve.

In their definition of entrepreneurship, Wennekers and Thurik (1999) emphasised the perception and creation of new economic opportunities, combined with a willingness and ability to introduce ideas into the market, in the face of uncertainty and other obstacles. Hence, entrepreneurship is a type of behaviour that concentrates on opportunities rather than resources and is essentially a behavioural characteristic of individuals, although commonly taking place in an organisational context. By emphasising economic opportunities and their exploitation within markets, the application of Wennekers and Thurik's definition of entrepreneurship, together with that of Knight, casts doubt on the validity of considering all leaders of social enterprises as entrepreneurs. Such people may be able to engage in entrepreneurial behaviour in much the same way as public sector employees can, but not legitimately be considered as entrepreneurs, in relation to such definitions. Entrepreneurs are business owners whose behaviour involves financial risk for them, although the term entrepreneurship may be used to embrace a wider range of entrepreneurial behaviours. Moreover, while social enterprises may be run as efficient businesses, their prime purpose does not lie in profit generation but in building social capacity and responding to under met social needs (Amin et al, 2002).

One of the definitional issues that has been much debated in mainstream literature, and which is potentially relevant to discussions about social entrepreneurship, concerns whether or not self-employed people and small business owners are necessarily entrepreneurs. In practice, business owners perform both entrepreneurial functions (e.g. recognising new market opportunities, creating new ventures) and managerial functions (e.g. organising, co-ordinating), although the balance between these varies between firms and individual owners, as well as within firms over time. For example, an individual may be entrepreneurial in creating a new venture, whilst subsequently managing it conservatively. Additionally, Wennekers and Thurik (op cit) note that few business owners are pure Schumpeterian entrepreneurs or pure shopkeepers. From this it may be concluded that the lack of definitional clarity over social entrepreneurship is not significantly different from that in the mainstream entrepreneurship literature. However, the more fundamental distinction discussed previously remains.

### **3. Mapping The Social Enterprise Sector in the UK**

This section describes the baseline mapping exercise in the UK, commissioned by the Department of Trade and Industry (DTI) in 2004, in order to bring out some of the problems involved in improving the evidence base of the social enterprise sector. Whilst focusing on some of the practical issues arising in assembling the database, many of these issues have wider conceptual dimensions to them.

The starting point for the mapping exercise is the current definition of social enterprise included in the previous section. The DTI definition contains a number of key words and phrases that are important in guiding what should and should not be included. As far as this definition is

concerned a social enterprise is firstly a 'business' that is trading, which by implication means that organisations that are entirely dependent on grant income are excluded. However, unlike a privately owned business, a social enterprise must have social objectives as its primary purpose, rather than simply claiming to be socially responsible. As with any business, a social enterprise aims to generate a surplus, although instead of being distributed to private shareholders, these surpluses are mainly used to achieve the organisation's social aims.

Following the publication of the guidance notes early in 2004, the authors were commissioned by the DTI to co-ordinate the initial stages of the national mapping exercise (specifically stage (ii) below). Previous consultants, who were employed by the DTI to provide guidance for the national mapping exercise, had recommended that the mapping be taken forward in five main stages:

- (i) Compilation of initial databases for each region and devolved administration, containing all organisations listed at Companies House as Companies Limited by Guarantee or Industrial provident Societies.
- (ii) Validation and enhancement of initial databases by regional partners and the national co-ordinator
- (iii) A telephone survey of (a sample) of listed enterprises to establish social aims and trading level.
- (iv) Analysis, including estimation of economic contribution
- (v) Utilisation of data gathered as a resource for the social enterprise sector

Following the initial guidance, the aim of the mapping exercise was to gather baseline data for a 'core group' of social enterprises, recognising that it would be impractical and probably too costly, to collect information on all social enterprises. The core group was defined as organisations that satisfy three tests, with respect to registration, trading status and the pursuit of a social aim. More specifically, the three eligibility criteria were:

- Registered as Companies Limited by Guarantee (CLG) or Industrial Provident Societies (IPS);
- Generating at least 50% of their income from trading;
- Pursuing social objectives and principally reinvesting surpluses in the business or in the community.

In addition, it was also intended to capture information on 'additional groups' of social enterprises that meet the following criteria:

- Businesses which meet trading and social aims criteria but which are registered in some other form than CLGs or IPSs
- Generating between 25-50% of their total income from trading activity

The role of the national co-ordinator (i.e. the authors) was to facilitate the checking and enhancement of the initial databases (see (i) above) by so-called regional expert groups. The idea was that these groups of regional experts, which would be assembled by each RDA and devolved administration, would use their local knowledge to make recommendations for additions and

subtractions to the initial databases provided. Each group was chosen by the staff responsible for social enterprise in each RDA/devolved administration, in consultation with the national co-ordinator and the Social Enterprise Unit (SenU) at DTI<sup>3</sup>. The aim was to reflect the diversity of the social enterprise sector, whilst keeping each group to a manageable number (6-8 persons).

The initial databases were distributed to the convenors of each expert group at the beginning of February 2004. The national co-ordinator arranged meetings with the expert groups in each region/devolved administration, which were held during March 2004. The idea was that each expert group would go through the initial databases (which ranged from approximately 2000 to almost 10,000 organisations prior to the meeting and classify each organisation on the basis of what was known (if anything) about firstly its social aims and secondly its trading income<sup>4</sup>. The idea was to capture whatever knowledge existed at the regional and local levels, in order, on the one hand, to sift out organisations that were known not to meet the DTI's definitional criteria and, on the other, to add any organisations believed to be social enterprises that were missing. Expert groups were not expected to survey or contact listed organisations in order to complete this exercise, but simply to use whatever databases existed at the regional/devolved administration level, supplemented by their own knowledge (including tacit knowledge) and that which could be drawn on through the wider regional social enterprise network. The purpose of the meetings with the national co-ordinator in each region/devolved administration was to finalise the amended/enhanced databases, seeking ways to resolve any problems that may have arisen.

Following the meetings, the enhanced databases were returned to the national co-ordinator for

<sup>4</sup> The coding scheme adopted for both social aims and trading status allowed for uncertainty, particularly with regards to the proportion of total income from trading activity.

checking and collation, before submission to DTI. The enhanced national database will be used as a basis of the telephone survey (stage (iii)).

A number of definitional issues emerged from the meetings with regional expert groups as a result of their experience in applying the social aims and trading income tests. As far as social aims are concerned, key issues included what might legitimately be considered to be a social benefit and who the beneficiary group are. In this regard, the guidance we provided referred to ‘a reasonable person test’ of what constitutes community or wider public interest, emphasising that access to benefits provided by the organisation should be widely available and not confined to an unduly restricted group (DTI, 2003). Hence social benefits should extend beyond a particular membership group, unless the members are socially disadvantaged/excluded. This is supported by the charitable status test which states: *‘charities must benefit the community at large or a substantial section within it. They must not entirely exclude those of limited means’*.

However, when this interpretation of social aims was applied, concerns were expressed by some members of expert groups about the implications for certain types of organisation. The most consistently expressed concerns referred to worker co-operatives, which some felt justified inclusion because they believe that the empowerment which employee ownership offers employees is inherently social, alongside the working environment and employment created. However, application of the definitional guidance meant that some co-operatives were excluded, because the social benefits they offer do not extend beyond the members/employees of the worker co-operative.

Faith-based organisations were another group that featured in the discussions of several expert groups. One view was that all faith-based organisations have social aims, even if they are exclusive to members, on the basis of their contribution to building social capital and contributing to local communities. However, a more common view was that there needs to be specific social benefits (i.e. other than the spiritual), which are available to a wider group of members, for faith-based organisations to qualify.

Other organisational types discussed in these expert meetings included colleges and higher education institutions, although because of the business element in the definition, most agreed that it was only the trading arms of these organisations that could be eligible; business support organisations; sports clubs, where discussion focused on who the beneficiaries were; and organisations, such as Connexions, which provide information and advice for young people. Housing associations were another controversial type for some expert groups, with concern expressed over cases where the creation of an association simply involved the transfer of housing stock from a local authority to a housing association. An underlying issue concerned the difference between the results of applying the test and what some saw as the spirit of social enterprise.

For some 'experts', a key issue is that the exclusion of many worker co-operatives omits one of the traditional elements in what has been seen as the social economy, whilst many voluntary sector organisations that have not traditionally been considered part of the social economy (and which may not consider themselves to be social enterprises) are included. Another issue raised concerned the treatment of charities, which were included in the mapping if registered as a CLG.

Although other legal forms may qualify for the additional group of social enterprises, these were not included in the mapping exercise because they were being covered by a separate study.

However, the aim throughout was to systematically apply the tests and treat each case on its merits, rather than to make judgements about generic types. Of course, the final decision concerning whether or not particular organisations should be included in the core or additional group, depends on the responses of organisations participating in the telephone survey, which will be undertaken once the database of potentially eligible organisations has been assembled. Application of the trading income test also led to considerable debate in some expert group meetings. A dictionary definition of trading income refers to 'income from sales of goods and services' or 'payments received in direct exchange for a product or service'. DTI guidance is that trading income specifically excludes income from grants, subsidies, supporter's membership fees (unless these are linked to the receipt of specific services), voluntary contributions and fundraising, although it does include service level agreements with public bodies. Service level agreements are contracts between service providers and customers that define the services provided, acceptable and unacceptable service levels, liabilities on the part of the service provider and the customer and actions to be taken in specific circumstances.

One area of concern in most expert groups was the exclusion of organisations in which income from trading represents less than 25% of total income. It was argued that many of these organisations will be fledgling or emerging social enterprises and a potentially important target group for intervention. This would seem to be a potentially strong argument, although to include all organisations meeting the social aims test, whilst undertaking some trading activity (i.e. below the 25% level), would include many organisations with very little trading income.

However, a more fundamental problem concerned the difficulty of distinguishing trading from grant income, especially when some organisations may refer to contracts as grants. Whilst, in principle, grants may involve income that is not necessarily related to specific levels of output, it was reported in a number of expert group meetings that the distinction is becoming an increasingly fuzzy one, because of the inclusion of clawback clauses for many grants. This means that in cases where a service is not delivered, or the outputs are below the level in the grant application, some of the grant must be repaid. However, whilst not a black and white distinction, most recognised that service level agreements include more specific output-related funding than grants; for example, where the income received is on a per capita basis or according to the number of training places actually provided.

The practical difficulties experienced in the regional meetings and the nature of the discussions in the so-called regional expert groups over definitional issues reflect more fundamental differences concerning the nature of social enterprise, reflecting different traditions.

#### **4. Assessing The Impact Of Social Enterprise On Local Economic Development**

Alongside improving operational definitions and completing the baseline mapping exercise, the third element in the development of an evidence base for social enterprise concerns assessing its contribution to local development. In this regard, it is important that the methodology used to assess this contribution takes into account a full range of potential impacts, which include both direct and indirect benefits. Potential direct benefits include the provision of goods and services and employment benefits. Potential indirect benefits include the multiplier effects of any local

spending through purchases and spending by employees, as well as any contribution to building social capital. There also needs to be a combination of 'hard' and soft' indicators used in order to capture the full range of benefits (Figure 1).

Insert Figure 1 about here

An attempt was made to operationalise such an approach in a recent study of social enterprises in rural Devon (Smallbone et al, 2003). The methodology employed involved a series of in-depth case studies of 30 social enterprises located in rural Devon. These included regeneration organisations and development trusts; community shops; community centres/village halls; transport schemes; community finance initiatives; housing associations; and child care organisations. The 30 cases were selected to capture the variety of different types of social enterprise located in the county. For the purpose of the study, social enterprises were defined as organisations that meet social aims by engaging in trading activities, from which any surplus generated is not for personal profit. Since the design of the study predated the publication of the definitional guidelines for the national mapping exercise, the definition used in this study was broader than that described earlier in the paper. These 30 enterprises were fairly evenly divided between organisations that were completely, or almost completely, dependent on contracts or grants from the public sector; those financed through a combination of sources, including trading income and public funding; and those totally dependent on trading income, either from sales or rental income. Evidence from the case studies enables us to draw some conclusions about the nature of the contribution of social enterprise to rural development in the county, although an assessment of the extent of this requires a larger scale survey.

One of the main benefits of social enterprises to rural Devon was the contribution to service provision, particularly those enterprises that are providing basic services to rural communities (e.g. transport, shops). These are services, which in rural areas the private sector is not currently willing to supply and the public sector is unwilling to solely fund, representing both a market and publicly funded gap. This contribution is particularly relevant in a rural context, in view of the continuing decline of a range of services, such as shops, post offices and public transport services in rural areas, which particularly affects low income households and socially disadvantaged groups (including mentally ill, people with disabilities, young, elderly, unemployed, and families on low incomes), with low levels of personal mobility.

Poor access to transport was being tackled by rural community transport initiatives providing both general bus services when public transport is inadequate or non-existent, and specialist services (such as routes to schools, hospitals, delivering meals and laying on transport for the less mobile). The four community shops interviewed were found in villages where all other shops had closed, because it was not financially viable for private enterprise to operate. Where these shops also had a post office, they were able to provide a range of banking and other services that help to reduce financial exclusion in certain social groups. Many rural areas lack childcare provision. In this context, nurseries and crèches provided by social enterprises allow parents to go back to work either full-time or part-time, as well as being an important opportunity to allow children to socialise.

Community centres were providing a local service by letting out rooms to community groups, providing information and, in some cases, running a café. One of the centres was hosting 25 organisations on a regular basis (once a week), renting out rooms to a total of approximately 50

organisations during the year. Through these activities, they were able to build a strong bond within communities and provide social support for groups, such as the elderly. A number of community centres were also involved in training provision. Some were well connected with other organisations and public agencies and had incorporated signposting as one of their activities, which included putting individuals or organisations in touch with other organisations or businesses. Village and community centres are a type of social enterprise with an important potential role as a necessary part of the social infrastructure of rural communities, but with potential contributions to the economic life of the countryside also, such as by hosting training workshops.

On the basis of the case studies investigated, social enterprises are not a major generator of jobs in rural Devon. Moreover, wage levels are typically low and the high turnover of staff, in low skilled occupations particularly, is comparable with private sector businesses. There was also a relatively high degree of job insecurity, particularly in those social enterprises more dependent on public funding. Social enterprises were involved in various networking activities with other organisations and businesses, which involved sharing knowledge, ideas and space or staff with other organisations and businesses, reflecting the contribution of this type of enterprise to social capital.

Although a pilot study, this research provides some evidence of the nature of the contribution of social enterprise to rural development. A more comprehensive assessment will be easier, once the DTI's mapping exercise is completed.

## **5. Conclusions**

There is no doubt that the social enterprise sector in the UK is attracting increasing attention from policy makers, although effective policy development is restricted by the limited nature of the evidence base that currently exists. The baseline mapping exercise that is currently being undertaken by the DTI is an attempt to get a better idea of the scale of the social sector and the characteristics of organisations that are active in it. This is essential if the potential and actual contribution of the social sector is to be estimated, which is necessary if public funds are to be used to support it (or parts of it) in different ways. At the same time, the sector is difficult to define, mainly because it represents such a diverse mix of organisations, which may share a loosely defined social purpose, but in some cases little else. Whilst the current government definition has established a clear set of principles, their application in practice raises some problems. The systematic application of the tests derived from the definition results in the inclusion of some organisations, which few would have previously considered part of the social economy, not even the organisations themselves, whilst excluding other organisations which historically have been one of its foundations.

At the same time, the attempt to establish a clearer set of guidelines to define the sector must be applauded. It may be argued that because of the lack of clear conceptual definitions, the current approach will ultimately lead to greater clarity. Fundamentally, there are two related sets of issues: firstly agreeing on the definitional criteria; and secondly, providing workable guidance for operationalising them. As far as the first is concerned, while most would agree that a social enterprise is an organisation that combines social aims with some attempt to operate as a business, problems arise when attempts are made to define social aims operationally, mainly because of the value judgements implicit in such an exercise. Our attempts to use Community

Interest Company (CIC) and charitable status guidance emphasised wider social benefits, but one is still left to interpret the 'reasonable person test'.

The other key problem involves interpreting precisely what operating as a business means in practice. DTI guidance has set fairly demanding trading income criteria for social enterprises to qualify for the core group in the mapping exercise (i.e. 50% of total income), although it remains to be seen how many organisations will actually qualify when the baseline mapping exercise is complete. At an operational level, the problem focuses on exactly what constitutes trading income. If service level agreements are included, there can be considerable problems involved in distinguishing these from grants, since few grants these days come without some expectations with regards to outputs. Conceptually, we suggest that a service level agreement or contract should only be regarded as trading income if it is won in competition with other organisations, although this raises additional problems at the operational level.

From a policy perspective, once the results from the baseline mapping exercise are publicly available, there is a need to systematically assess the nature and extent of the contribution to local, economic and social development, perhaps in comparison with public and private sector alternatives. However, the evidence base should also include a better understanding of how social enterprises develop, recognising the heterogeneity of types of organisation involved. This includes those emerging from community development or regeneration projects, which may move slowly towards the generation of trading income, as well as more commercially oriented organisations (e.g. community shop, community transport), which may not be completely self financing, but which are inherently trading enterprises. Indeed, in the first case, one might

question whether they can ever become free from a dependence on the public purse, which on the basis of the evidence presented by Amin et al (2002) is doubtful.

Another priority research area, which is closely related to an understanding of the process of social enterprise development, is to better understand the nature of entrepreneurship in the social sector. This has implications for policy as well as being of policy significance because there is a feeling that the entrepreneurship discourse may be overstating the entrepreneurship involved. For example, some critics suggest that part of the current policy push is driven by a desire on the part of government to improve the quality of management in voluntary sector activities, as part of an attempt to encourage organisations dependent on public funding to diversify their income base. We also need to increase our knowledge about so-called social entrepreneurs; in other words, the key individuals behind the social enterprises, using more discriminating typologies rather than including all leaders of social enterprises as social entrepreneurs. This is important conceptually, if we are to better link research in this field to the mainstream entrepreneurship literature (disparate as it is). It may also be important for policy development in helping to define the support needs of such people and their enterprises at different stages of their development.

### **Abstract**

The paper sets out to review entrepreneurship in transition countries, assessing the extent to which theories and concepts of entrepreneurship developed in a market economy context can provide an appropriate interpretative framework. This is done in order to develop propositions for a model of entrepreneurship under transition conditions, which captures (1) the distinctive features of entrepreneurship (2) the context for entrepreneurship in these countries and (3) the

entrepreneurial process. The paper builds on previous papers by the authors, selectively using empirical evidence to support appropriate conceptualisation.

## **1. Introduction**

Alongside the liberalisation of prices and the creation of market institutions, the transformation of centrally planned into market economies involves the development of a privately owned business sector, through a combination of the privatisation of former state-owned companies and the creation of completely new enterprises. In principle, entrepreneurship (particularly in the form of the creation of new ventures) can contribute to the process of transforming former socialist countries into democratic, market based systems in a variety of ways. The potential role of entrepreneurs includes generating employment; using privatised property for production; contributing to the development of a diversified economic structure; contributing to the innovative capability of the economy; and contributing to economic development through the generation of foreign sales and/or import substitution. In addition to these essentially economic roles, entrepreneurship can also contribute to the emergence and development of a middle class that is fundamental to the wider process of transformation to a market based democracy.

However, achieving this potential contribution has presented many challenges in a context where, in most socialist countries, private business ownership was previously considered illegal; the resources for establishing and developing businesses extremely limited and the external environment contains many institutional deficiencies, compared with most mature market economies. Not surprisingly, some 15 years after the start of the reform process, there is considerable variation between countries in the extent to which a facilitating environment for the development of entrepreneurship has been created. As a result, it is inappropriate to refer to transition countries as if they are an undifferentiated, homogeneous group, any more

than so-called market economies may be considered as a uniform group. Instead, it may be more appropriate to think in terms of a continuum from central planned economies at the one extreme to liberal market economies at the other, with individual countries situated at different points along it. In the context of former socialist economies, positioning along this continuum is heavily influenced by the extent of the commitment of government to market reforms, which is demonstrated through their actions with respect to progress with privatisation; the extent to which there is price liberalisation; and the role of government with respect to the creation and effective operation of market institutions as well as their attitude towards entrepreneurship.

In this regard, assessment by the European Bank for Reconstruction and Development (EBRD) shows wide variation between countries with respect to dimensions, such as large and small-scale privatisation; price liberalisation; and banking reform, where the rate of progress has typically been slower. Whilst a detailed classification of all so-called transition economies may be inappropriate here, a broad distinction can be made between Central and Eastern European countries (CEECs) that are either current members of the EU, or in the next group to join; and former Soviet republics (other than the Baltic States). Although considerable variations can still be identified within each of these groups, such a distinction can be justified, not least because of the influence of EU accession in driving the process of institutional reform (Smallbone & Welter, 2003b).

As a consequence, when analysing entrepreneurial behaviour with the aid of concepts and theories developed in a market context, so-called transition economies cannot be treated as a single group. In practice, a growing gap can be identified between CEECs that are essentially emerging market economies and countries where the framework conditions for establishing a

market environment have still to be effectively installed, particularly where there appears to be no current political will to do so (as in Belarus). For the purpose of this paper, we will use the term 'early stage transition' to describe such countries, without meaning to imply any necessary progression to later stages.

In this context, the paper sets out to review the development of entrepreneurship in countries that have emerged from central planning, in order to assess, on the one hand, the extent to which theories and concepts of entrepreneurship developed in a market economy context are appropriate to analysing this phenomenon and, on the other, the implications of the types of entrepreneurial behaviour observed in transition conditions for existing theory. This is done in order to develop propositions to subsequently feed into the development of a conceptual framework of entrepreneurship under transition conditions, which captures (1) the distinctive features of entrepreneurship, (2) the context for entrepreneurship in these countries and (3) the entrepreneurial process.

One of the issues this raises concerns the nature of the evidence base on which to develop or test theories and apply concepts. In this regard, Scase (2003) refers to a lack of reliable data leading, amongst other things, to 'extremely unreliable estimates of the real significance of entrepreneurship and small business ownership in a transition context (Vickerstaff et al, 1998). However, whilst secondary data constraints, and the difficulties of systematically conducting empirical research in some of the former Soviet republics, should not be underestimated, the challenge for researchers is to develop methodological approaches that are appropriate to the context in which they are being used, as well as to the research questions they are addressing. Large scale surveys can be undertaken in transition circumstances, and can produce potentially useful results, provided they are interpreted in the context in which

the data were gathered, with the limits to generalisation clearly defined. At the same time, such methods can benefit from being used in combination with more process-oriented qualitative approaches, which on some issues can produce quite different results than those based on survey responses (Welter and Smallbone, 2003).

The empirical underpinnings of the paper comprises a number of studies since 1993, in which one or both the authors have been involved. These include studies of the survival and growth of manufacturing SMEs in Poland and the Baltic States, based on interviews with 600 businesses (Smallbone et al, 1997); internationalisation and SME development in Central and Eastern Europe in 1997-98, which also involved a large scale survey of SMEs in Poland, Bulgaria and the Baltic States (Smallbone et al, 1999a); a study of the support needs of Small Enterprises in Ukraine, Belarus and Moldova, involving 600 interviews with entrepreneurs, as well as with providers of business support (Smallbone et al, 1999b); the contribution of small businesses to regional economic development in Ukraine, Moldova and Belarus, which involved case studies, as well as a large scale survey (Smallbone et al, 2001); employment, SMEs and Labour Markets in the Russian Federation and Moldova, involving a survey of more than 1000 SMEs and case studies also (Welter et al, 2000); innovation, small and medium enterprises and economic development in Ukraine and Belarus, which also combined case studies with a survey' (Smallbone et al, 2002); female entrepreneurship in Ukraine, Moldova and Uzbekistan (Welter et al, 2003); entrepreneurial strategies and trust in low trust and high trust environments of East and West Europe.

## **2. Concepts of Entrepreneurship under Transition Conditions**

In considering concepts of entrepreneurship in a transition context, it may be helpful to briefly discuss a *number of definitional issues* that are potentially relevant. Entrepreneurship involves both inputs and outputs. Inputs involve entrepreneurial skills and qualities, with participation in the competitive process as the main output. A firm is a vehicle for transforming the personal qualities and ambitions of entrepreneurs into actions and outputs. Context may be viewed as a third dimension of entrepreneurship, since the specific internal organisational and external operating contexts provide the framework within which the input and output dimensions can take place (de Wit and Meyer, 1998).

Entrepreneurship is also a multidimensional concept, which can be analysed at different levels. Firstly, entrepreneurship is concerned with individuals in terms of their roles, traits and actions, integral to which are their learning abilities and behaviours (Pedler, et al. 1998).

Individual entrepreneurs can operate on their own or in teams. The second dimension is at the firm level and the third at the aggregate level of industries, regions and nations. A consideration of the role and characteristics of entrepreneurship in a transition context involves linking the individual level to the aggregate level, as the context for entrepreneurship is a distinctive one, with a much stronger influence on entrepreneurship compared to mature market economies (cf. section 3). Moreover, in any context, entrepreneurial learning activities need to be analysed as a reciprocal process between an individual entrepreneur/firm and the external environment, with the entrepreneur and his/her environment interacting and influencing each other (Berger and Luckmann, 1967).

Richard Scase (1997; 2003) has contributed to the debate about the role of entrepreneurship under transition conditions by distinguishing between entrepreneurship and proprietorship,

based on “contrasting psychologies of business founders; their attitudes towards trading; and their orientation towards capital accumulation” (Scase, 2003, p 67). According to him, entrepreneurship refers to a person’s commitment to capital accumulation and business growth, whereas proprietorship describes the ownership of property and other assets, which may be used for trading purposes to realise profits, but which are not utilised for longer term purposes of capital accumulation. Any surpluses generated by proprietors are likely to be consumed rather than re-invested for business purposes.

In the pursuit of capital accumulation and long term growth, the entrepreneur may forego personal consumption and may actively search out market opportunities, which involves taking risks and coping with uncertainty. In the case of proprietorship, according to Scase, the motives are quite different, since surpluses are not re-invested in the business for future long term capital accumulation but rather consumed and used to sustain a specific standard of living. According to Scase, in the transitional economies of Russia and Central Europe, proprietorship rather than entrepreneurship best describes the majority of small business activity. His assessment is that whilst numerically significant, particularly in sectors such as services and retailing, offering employment and providing earnings, these proprietors are incapable of constituting an indigenous force for economic development at the macro level.

Although Scase focuses on transition economies, his distinction between entrepreneurs and proprietors is not specific to a transition context. The lack of commitment to long term capital accumulation, with an emphasis on consuming any surplus rather than re-investing it in the business (proprietors according to Scase), is a common feature of many small firm owners in mature market economies. It is one of the reasons why few small businesses grow to any great extent. Perhaps the issue needs to be viewed as part of a wider discussion about the role of

entrepreneurship and small business in economic development, rather than being viewed as a specifically transition issue. In this context, the key point to emphasise is the importance of Schumpeterian-type entrepreneurs to economic development in any economy and the creation of 'newness', such as in terms of products and processes, although as Wennekers and Thurik (1999) note, in practice, few business owners are either pure Schumpeterians or pure 'shopkeepers'.

Scase's approach is related to an earlier concept developed by Bögenhold (1987), who distinguished between entrepreneurship motivated by economic needs and entrepreneurship, which is driven by a desire for self-realisation. More recently, the GEM consortium have distinguished between 'opportunity' and 'necessity' entrepreneurship, based on the reasons given by entrepreneurs for starting a new business, with necessity entrepreneurship tending to dominate in transition and developing countries.

However, some empirical results have challenged the appropriateness of such a simple dichotomy. For example, it has been suggested that concepts of 'necessity' and 'opportunity' entrepreneurship are overly simplistic classifications, especially in the context of the conditions pertaining during early stages of transition, where it may lead to overly negative conclusions about the contribution of entrepreneurs (Smallbone and Welter 2003a). This is partly explained by the specificities of external conditions that can lead even well-educated people being presented with limited opportunities for satisfying and sufficiently rewarding employment, which contributes to entrepreneurship attracting individuals with high levels of human capital. As a result, many entrepreneurs in transition environments are well equipped to identify and exploit opportunities as they emerge over time, even if the initial reasons for becoming an entrepreneur in the first place can reasonably be described as 'necessity'. It is

also influenced by the learning experience of individuals, which can contribute to changes in their motivation and behaviour with respect to entrepreneurship over time. Even in those post socialist countries where institutional and other external conditions for private entrepreneurship are deficient, entrepreneurs set up businesses for a variety of reasons, including 'pull' as well as 'push' factors. Moreover, the aims and orientation of entrepreneurs can change over time, as new opportunities are presented, the business environment improves and/or because of the development of their own entrepreneurial capacity.

Concepts such as proprietorship/entrepreneurship and the distinction between opportunity- and necessity-driven entrepreneurship implicitly focuses on the attributes of individuals, which can be measured through, for example, the motives and objectives of entrepreneurs, or, as Scase emphasises, through "psychological profiles". This draws on the psychological traits approach, which has been widely criticised for its restrictive focus on entrepreneurship as a personal phenomenon, divorced from its social and institutional context.

New venture creation must be viewed as a process, which means that the aims and motivations of (potential) entrepreneurs can operate at different levels, including deep-seated antecedent influences, as well as immediate triggers. The entrepreneurship literature contains numerous models and frameworks developed to analyse the process of starting a business, most of which have been based on research undertaken in market economies. In the context of a transition environment, such frameworks are potentially useful for analysing the barriers faced by entrepreneurs and potential entrepreneurs, since it is likely that these barriers will vary at different stages of market development. At the same time, the distinctiveness of transition conditions raises the question of whether these models can fully capture the entrepreneurial process in post socialist countries.

One issue that arises in countries that until ten years ago were operating under a centrally planned system, concerns the potential of entrepreneurial activities during the socialist period to 'breed capitalism' (Kornai 1992), thus acting as the 'antecedent influences', identified by authors such as Cooper (1981), which have potential implications for the balance between productive and unproductive entrepreneurship (Baumol 1990). Although in Central and Eastern European countries private entrepreneurship lost its major role with the introduction of a centrally planned economic system, different forms of private entrepreneurship co-existed beside state ownership and entrepreneurship within state enterprises during the socialist period. In this regard, we can distinguish between the formal and the grey economy (consisting of the second and the illegal economy), where 'boundaries' frequently changed following political trends of liberalising and restricting private ownership and entrepreneurship.

In addition, Rehn and Taalas (2004) have emphasised how entrepreneurship flourished during the Soviet period in the daily lives of individuals, as they struggled to cope with the material shortages that were a common occurrence in the Soviet system. In pointing out the importance of interpreting entrepreneurship in its specific social context, Rehn and Taalas raise definitional issues concerning the nature of entrepreneurship, which they interpret as a 'search for opportunities and beneficial outcomes in economic interactions' (Rehn and Taalas, op cit, p246) which, through necessity, made most citizens of the USSR entrepreneurs, in the Rehn and Tallas sense.

All this contributes to a different background of entrepreneurs in transition conditions, which interacts with characteristics of the institutional environment to influence the specific patterns

of their entrepreneurial behaviour. For example, in early stage transition countries, where progress with market reforms has been slow or stalled, we can frequently observe a persistent type of behaviour that may be characterised as ‘muddling through’ and ‘rule avoiding’, but which nevertheless represents a learned response to a particular set of external environmental conditions (Welter and Smallbone 2003). Examples include economic activity that is at least partly in the shadow economy, tax evasion, and a heavy reliance on personal network contacts in daily business life.

Principally, entrepreneurs fall back on behaviour they have previously applied successfully, as long as they are facing familiar situations, for which ‘closed loop’ learning can provide the basis for making an adequate response. However, faced with unpredictable or even unknowable change situations, tried and tested routines may be inadequate. An example relates to the rapid series of changes and instability of macro and institutional conditions at the beginning of the transition process. Although this situation would require a change in entrepreneurial behaviour, cognitive biases inherent in decision making processes could reinforce a muddling-through approach and unstructured behaviour of entrepreneurs. The conflict theory of decision making explains this in terms of ‘avoidance’ (Lyles and Thomas 1988). Once an entrepreneur has settled on a particular course of action, (s)he will only change her behaviour in cases where current actions lead to negative results, which are higher than the risk coupled with taking an unknown course of action.

### **3. The Institutional Embeddedness of Entrepreneurship in a Transition Context**

In a transition context, the environment is characterised by a high level of uncertainty, rapidly changing external conditions and institutional deficiencies, which result in significant

additional operating costs for businesses without contributing any additional value (Smallbone and Welter 2001b). The key question is whether or not this results in fundamental differences in the way that entrepreneurs identify and exploit opportunities, compared with their counterparts in mature market economies and/or whether the outcomes, for example, in terms of the types of organisation established are distinctive. Although much of the research on entrepreneurship in transition economies has focused on entrepreneurs and their behaviours at an individual level, the specific characteristics of the external environment under transition make the latter a potentially more dominant influence on entrepreneurship than in a mature market context, where external conditions are typically more stable.

So far, with the exception of the eclectic approach to entrepreneurship (cf. Verheul et al. 2002) most entrepreneurship theories focus on micro-level influences in order to explain new venture creation and the development of entrepreneurship, taking the institutional environment as given. However, there is considerable empirical evidence from transition economies, which shows the external environment to be one of the dominant feature influencing the nature and pace of entrepreneurship (e.g., Peng and Heath 1996, Peng 2000, Polishchuk 2001, Smallbone and Welter 2001a, 2001b). It can be argued that in any context enterprise behaviour results from a dynamic inter-relationship between internal (i.e. both organisational and personal characteristics) and external conditions, but in situations where market conditions are only partially installed, the institutional context becomes a critical factor. Referring back to the introduction, where a continuum of market development was described, if entrepreneurship is viewed as an individual act, undertaken in specific social/institutional/environmental conditions, then the balance between individual and environmental factors in explaining entrepreneurial behaviour is likely to vary at different points along that continuum.

In this context, an institutional perspective can be used to explore differences in the embeddedness of entrepreneurship in post socialist and market-economy environments and the influence on entrepreneurial processes. Institutions represent the ‘formal’ and ‘informal’ constraining and enabling forces with respect to entrepreneurship, creating opportunity fields (e.g., through laws) and influencing the collective and individual perception of entrepreneurial opportunities. Nooteboom (2002: 34) defines institutions as “things that constrain, enable and guide behaviour”, consequently discussing a separation between so-called surface institutions, which would enable and constrain, and deep structures, which would guide individual behaviour. However, Nooteboom himself concludes that a clear separation is not viable due to recursive and feedback links between both concepts, illustrating the difficulties in achieving a clear-cut distinction between formal and informal institutions.

One prominent example of formal or regulatory institutions is laws, which might create new opportunity fields for entrepreneurs, as happened in transition economies with the introduction of property rights allowing for private ownership. On the other hand, a deficient legal infrastructure (e.g., implementation gaps, a lack of judges, economic courts) could restrict entrepreneurship, especially where an ‘institutional void’ (Polishchuk 1997) allows for discretionary actions of administration, thus fostering rent-seeking, corruption and non-compliant or defiant behaviour of entrepreneurs. Normative and cultural-cognitive elements contain the collective sense making and individual understanding of societal values and rules respectively, which depends on previous experiences and knowledge.

The nature and extent of entrepreneurship across different environments reflect particular settings of institutions and enforcement mechanisms (Scott 2001, Honig and Karlsson 2004).

Formal institutions are enforced by coercive mechanisms as mainly set down in government rules, whilst informal institutions are enforced by normative and mimetic mechanisms.

Normative mechanisms push entrepreneurs to follow codes of behaviour as set out by a specific community such as industries, business associations, families or ethnic groups. They assist in creating legitimacy, which is of particular importance for nascent entrepreneurs and entrepreneurs in environments such as the transition context, where they face an additional degree of liability of newness. Formal mechanisms to ensure normative behaviour include regulations such as licensing, registration or accreditation (Scott 2001), while informal institutions are also enforced by trust (Welter 2003b, Welter et al. 2004).

Normative pressures, as codified in informal institutions, regulate entrepreneurs' behaviour and restrict their options, thus often forcing entrepreneurs to comply, even when they have to employ illegal actions. One such example is the Russian tax system. When paying taxes, entrepreneurs face a bundle of unwritten rules such as bargaining over the law, making friends within the tax authority, observing the formalities (i.e., filling in fictitious statements) and knowing their limits, which applies to both taxpayers and inspectors (Busse 2002). Again, these institutions are partly founded on Soviet predispositions, where the individual bureaucrat was the ultimate decision-making authority, rather than a law or written regulation itself (Busse 2002: 215), although they also result from regulatory shortcomings and gaps in implementing the new institutional frame.

In a transition context, several studies have confirmed the occurrence and persistence of avoidance behaviour (e.g., Frye and Shleifer, 1997; Hendley et al., 2000; Gustafson, 1999), which can be explained by a highly volatile institutional environment, encouraging entrepreneurs to fall back on learned behaviour. Feige (1997: 28) characterises such actions as

the 'legacy of non-compliance', which dominated most of the tolerated and non-legal entrepreneurial activities in Soviet times. Other examples of entrepreneurial behaviour reflecting a response to specific institutional conditions include a high degree of networking, based on personal connections; particular financial bootstrapping tactics; and diversification or portfolio entrepreneurship (Welter and Smallbone 2003). With regard to networking, entrepreneurs draw on behaviour, which was widely used during Soviet times, namely reciprocal favours ('blat'). During the Soviet period, 'blat' was an integral part of the everyday lives of Soviet citizens, providing a mechanism for 'realising the hidden potentials of the system' (Ledeneva 1998). Such behaviour represents an integral part of the inheritance of citizens in transition countries, originating from the Soviet period and one of the mechanisms for dealing with resource constraints facing entrepreneurs during the transition period.

Another enterprise reaction to the external environment in transition economies concerns the so-called financial strategies of SMEs, in a situation where access to finance from formal sources is extremely scarce. Here, financial bootstrapping is used including, for example, serial entrepreneurship as one way for SMEs to accumulate the financial resources necessary to start a business in a context where the financial system is inadequate (Smallbone and Welter, 2001a). This often is extended to portfolio entrepreneurship and diversification particularly in sectors such as manufacturing where access to external capital is scarce and demand may be fluctuating and uncertain. The establishment of a retail shop or market stall by a clothing manufacturer is one example. In a transition context, such behaviour does not only reflect 'normal' risk behaviour of entrepreneurs, but it can also be encouraged by certain institutional deficiencies. For example, diversification commonly represents a deliberate strategy of making business success less visible to officials and those who may seek to make

money from offering 'protection'. Although our evidence from several projects also implies that motives for diversification strategies include the realisation of market opportunities, as well as ongoing access to markets, the role of both portfolio entrepreneurship and product diversification as a means of overcoming (short-term) financial constraints is even more important, especially with respect to enterprises with high investment and working capital needs.

In addition, case studies show that diversification in most cases results in a broad and apparently unrelated portfolio of activities. Thus diversification strategies of enterprises in a transition context, particularly in early stage countries do not mainly reflect long-term strategic considerations. They chiefly express short-term behaviour to overcome financial and environmental constraints and institutional deficiencies. This emphasis on behaviour driven by short term expediency, necessary for a business to continue to operate, is also reflected in the reported pattern of use of advice and assistance from external sources, which in early stage transition environments, is typically focused on the use of legal and tax consultants, rather than on help (e.g. with marketing) associated with improving the basis for longer term business development (Smallbone et al., 2001c).

Although such behaviour may fall short of the optimal, standard set of economic man assumptions, it may be viewed as a rational entrepreneurial reaction to the given institutional framework. In adverse, unfamiliar and fragile environments, entrepreneurs keep a low profile, mainly avoiding official regulations whenever possible, or attempting to conform, which is made difficult in environments with rapid institutional changes. Thus, environments with institutional gaps generally favour a muddling-through type of behaviour (Barrett 1998). New and unfamiliar environments lack the basic strategic options, which have to be tested and

learned in a trial and error manner, going from simple to more complex patterns over time (Welter 2003a). In fragile and turbulent environments, entrepreneurs have to decide and (re-) act rapidly, whilst the deficient institutional settings re-enforce institutional mistrust.

In this regard, the concept of path dependency helps to explain rule-avoiding and seemingly sub-optimal behaviour. Conflicting formal and informal institutions encourage individuals to recur to familiar courses of action. If successful, this tends to reinforce trusted and known codes of conduct, resulting at the individual level in an 'escalating commitment' of entrepreneurs to viable, but not necessarily the best courses of actions (Whyte 1986). This in turn further constrains the required adaptation of informal institutions, often resulting in vicious circles and low-level efficiency traps for entrepreneurial behaviour, which are a widespread phenomenon in transition economies, especially in the early phases of transition (Kuznetsov 1997).

From an economic point of view, these 'lock-in effects' foster sub-optimal resource allocation, resulting in unproductive entrepreneurship as described by Baumol (1990). In such situations entrepreneurship remains restricted, the number of firms small and their contribution to economic development in terms of jobs, innovation and external income generation rather limited. As a result, institutional change becomes an important resource needed to initiate entrepreneurship, particularly in uncertain and unstable contexts.

Institutional change positively influences entrepreneurship when it removes or lowers barriers to market entry and market exit, thus creating opportunity fields for entrepreneurs, and vice versa. Examples of positive institutional changes include the introduction of private property rights at the beginning of the transformation process in some former socialist countries, or efforts to reduce regulatory burdens on enterprise in mature market economies.

#### **4. The Entrepreneurial Process under Transition Conditions**

One of the contemporary themes in the mainstream entrepreneurship literature is concerned with the creation and identification of entrepreneurial opportunities, which raises the question of whether the entrepreneurial process differs in a transition environment, and if so, in what aspects. In this context, some of the most recent models of the entrepreneurial process concentrate on opportunity recognition as an important element. For example, Beattie (1999) identifies two major models of the business creation process, differentiated by factors, which influence the opportunity recognition process. The first incorporates individual characteristics and environmental influences, understanding venture creation as an interactive process in which a person, his/her personality and interpretation of events influence any decision to start a business. Theoretically, this process is reflected, for example, in Shapero's concept of the entrepreneurial event, or Ajzen's theory of planned behaviour, which interprets entrepreneurial intentions as a function of feasibility and desirability.

The second model, of which Gibb and Ritchie's approach (1982) is an example, accepts venture creation as an outcome of the situations encountered and the social embeddedness of the entrepreneurs, thus implicitly picking up the theme of opportunity enactment outlined below. In this context, Kirzner's understanding of opportunities as a result of entrepreneurial alertness, entrepreneurial beliefs and information asymmetries (Kirzner 1997a, 1997b, 1999) emphasises the cognitive properties of (potential) entrepreneurs, which have an impact on entry patterns into entrepreneurship as well as subsequent development paths, thus indirectly influencing the extent and nature of entrepreneurship.

Shane (2003) distinguishes between two types of opportunities, i.e., Schumpeterian and Kirznerian ones. Schumpeterian opportunities result from disequilibrating situations, which makes them rare and innovative, involving the creation of new combinations. Sources of Schumpeterian opportunities include technological changes, political and regulatory changes and social and demographic change. Compared to this, Kirznerian opportunities are understood as being equilibrating, not requiring new information, less innovative, common and having a limited potential for discovery and innovation (Shane and Venkataraman 2000, Shane 2003).

Schumpeter's understanding of opportunities draws attention to environmental influences. This allows us to construct a link between the embeddedness perspective of entrepreneurship and an individual perspective, as the institutional framework influences the existence of opportunities as well as their recognition and possibilities for exploitation, which is explicitly recognised by Kirzner (1980) also. In this context, Shane (2003: 22-33) and Eckhardt and Shane (2003: 341-343) review empirical evidence for opportunity creation resulting from what they label 'exogenous shifts in information'. Several studies confirm that changes in technology, political forces, regulation and macro-economic influences, as well as social trends, are decisive influences on the existence and occurrence of new opportunities. All this applies to transition economies, which underwent fundamental changes when starting the transition from central planning economy towards a market-based system.

In a transition context, the Kirzner type of opportunities would be more apparent in later stages of transition, where markets have been developed and flows of information, ideas and knowledge from mature market economies represent an important source of innovation for enterprises (Smallbone et al. 2002). It is reflected in empirical surveys in more advanced

transition countries, where entrepreneurs complain about growing competition as one of their pressing business problems (e.g., Smallbone et al. 1999, Smallbone and Welter 2003b), whilst in early stage transition countries it is a lack of resources needed to realise an entrepreneur's business idea, together with a lack of institutional stability and unpredictability of institutional behaviour that is emphasised (e.g., Smallbone et al. 2002, Welter et al. 2003) At the beginning of the transition period, limited competition existed in many markets and market opportunities resulted from the shortages of certain goods, for which a latent demand existed. Such an environment was potentially a 'seedbed' for the Schumpeterian type of opportunities for entrepreneurs, although a variety of institutional constraints limited their ability to exploit these.

The embeddedness of opportunities in the formal institutional environment may be illustrated with reference to the initial changes in the institutional framework, which fostered entrepreneurship, when legal and administrative reforms made it legally possible for privately owned businesses to compete with state owned enterprises. Consequently, the number of private firms increased sharply in what has been described in Poland, for example, as "an explosion of entrepreneurship", facilitated by a removal of legal barriers to market entry, combined with the low intensity of competition and the existence of opportunities to earn monopoly profits and/or speculative incomes for a period (Piasecki and Rogut 1993). In explaining this, McMillan and Woodruff (2002) emphasise the results of distortions created by the planned economy, which created new market opportunities for potential entrepreneurs (e.g. in consumer services), once the establishment of privately owned enterprises became legal. However, in situations where a new formal framework is not (yet) properly implemented, 'loopholes' for 'creative' entrepreneurial activities may be created, although

some of these may fall into the category of more unproductive or even destructive entrepreneurship, as described by Baumol (1990).

Whilst focusing on the effects of the institutional environment on the exploitation of opportunities, Shane (2003, p160) recognises, in principle at least, that the former may also influence the discovery of opportunities. An example of institutional deficiencies creating opportunities for entrepreneurship is the development of business service consultancies in Ukraine, which is a new and emerging sector in such a context (Smallbone et al., 2002). The customers of these small consultancy firms are mainly private businesses, but also include some state and municipally-owned enterprises, which are increasingly looking for firms to supply a full range of services to avoid the necessity of employing several specialist companies. This 'full service' portfolio would include not just business advice, but also the acquisition of the necessary licences and permits needed to start and run an enterprise or, in some cases, to develop a new project. The consultancy firms that had developed to fill this niche were not 'grey sector' enterprises, but some of the most innovative and successful services firms in the study, which had responded positively to a market opportunity created by the specific institutional conditions pertaining in Ukraine at the time. Whilst the specific nature of the opportunities may be transient as the institutional environment for productive entrepreneurship improves, the behaviour demonstrated by these enterprises shows a high level of sensitivity and responsiveness to the needs of customers, which are themselves heavily influenced by institutional conditions.

Whilst Schumpeter puts more emphasis on the 'objective' side of opportunities and the related process of discovering and exploiting them, which he describes as a process of creative destruction, Kirzner (1997a: 51) implicitly understands this as an enacted phenomenon:

“Entrepreneurial discovery represents the alert becoming aware of what has been overlooked. (...) When the (...) human agent acts, he is determining what indeed he ‘sees’ in the murky future.” In this context, Kirzner (1979, 1997b) also refers to spontaneous learning and ‘surprise’ as a fundamental basis for entrepreneurial discoveries, allowing to include ‘serendipity’ and ‘luck’ as possible sources for entrepreneurial actions. A Kirznerian perspective draws attention to the interplay of ideas, beliefs and actions in defining and creating opportunities defying a simplistic view (Sarasvathy et al. 2003). Opportunities do not only “exist out there”, they are also created (Davidsson 2003). Opportunities emerge as individuals make sense of information and their actions, thus retrospectively ‘discovering’ and ‘recognising’ opportunities (Gartner et al. 2003).

As Gartner et al. (2003) argue, this opportunity enactment perspective draws attention to the fact that environments are also influenced by the scope of individual actions, which draws attention to the recursive links, existing between individual perceptions and environments, both simultaneously creating opportunities. This brings us back to the institutional embeddedness perspective on entrepreneurship outlined in section 3 above, which can be integrated into our discussion around opportunities in a transition context. Whilst formal institutions create opportunity fields for entrepreneurship, informal institutions influence the collective and individual perception of entrepreneurial opportunities, thus resulting in differences in the opportunity recognition process across contexts, cultures and countries. In a transition environment, this conception takes on particular importance, because the environment, in which opportunities are created, is qualitatively different compared to market economies and conditions can also change very quickly.

## **5. Conclusions and Implications**

Davidsson (2003) has emphasised the need for entrepreneurship research to acknowledge the heterogeneity of environmental conditions, outcomes and behaviours. The key question, as far as this paper is concerned, is the extent to which existing concepts and theories are appropriate bases for analysing entrepreneurship in transition conditions. The discussion shows that entrepreneurship in a transition context is not unique, as the essential principles of individual behaviour are the same regardless of the environment. However, where the process of entrepreneurship is distinctive is with respect to the specific interplay between individual entrepreneur/firm behaviour and the external environment, which changes as the process of transition unfolds. This emphasises the need to carefully review theories and concepts based on market economy principles for their usefulness and applicability in a context where market conditions are only partially established.

In this context, our selective review of literature and the empirical evidence base leads us to suggest a number of key propositions:

(i) In assessing the relevance of concepts and theories of entrepreneurship developed in market economies to transition environments, it is important to recognise the distinction between countries where the process of market reform is advanced, such that they may be better described as emerging market economies, on the one hand, and countries where the framework conditions for a market economy are still to be installed, on the other. In the latter case, external conditions may encourage unproductive, and even destructive, forms of entrepreneurship, with implications for its contribution to economic development.

(ii) As in mature market economies, the nature and extent of entrepreneurship in a transition context depends on individual goals and self-perceptions of the entrepreneur with regards to opportunities for venture creation and development, as these influence the steps entrepreneurs take to set up and/or expand their venture. All are influenced by the values and conventions within a society, as well as by the background of entrepreneurs, who for the most part have no prior experience of entrepreneurial activity in a market context, but are often educationally well qualified, with some experience of management.

(iii) The institutional environment influences the extent to which entrepreneurship develops, but also the forms that entrepreneurship takes and the behaviour patterns exhibited by entrepreneurs. In environments, where institutional settings are not clearly defined, as in 'early stage' transition countries, (nascent) entrepreneurs face a high level of uncertainty and ambiguity. This results in entrepreneurs falling back on learned behaviour, such as networking and avoidance strategies, which are to some extent path dependent. Although such behaviour might support firm performance and/or survival in the short run, it might be detrimental to firm development and growth in the long run.

(iv) Typologies which crudely classify individual as entrepreneurs or proprietors; or necessity- or opportunity-driven, fail to recognise the learning capability of individuals, interacting with a rapidly changing external environment. Whilst the point applies to entrepreneurship in all types of external conditions, it is a particular issue in transition economies, because of the reported dearth of opportunity driven entrepreneurs.

(v) Institutional change can create opportunities for entrepreneurship, as it opens up new fields which entrepreneurs can pursue. However, institutional change may also trigger and/or reinforce norm-deviant behaviour at the individual level. Conflicts within the institutional settings may encourage entrepreneurs to revert to familiar and known courses of actions (learned behaviour), based on the requirements of a previous institutional environment, thus fostering 'lock-in' situations where path-dependency prevents entrepreneurs from adapting to new context conditions.

(vi) Fostering entrepreneurship in 'locked-in' situations, where institutional change is needed, requires entrepreneurial (re-) learning. Institutional change itself may trigger entrepreneurial learning, but the learning capability of entrepreneurs and businesses influences the nature of the response.

(vii) Entrepreneurial opportunities in a transition context differ across the various stages of transition, being linked to the institutional environment. In early stages where a new institutional framework is in the process of being created, Schumpeterian opportunities result from disequilibrating situations. Kirzner type opportunities (equilibrating, less innovative) would be more apparent in later stages of transition, where markets and business environments have been developed and are more stable, thus forcing nascent entrepreneurs more and more into imitative new ventures.

The implications for further research on entrepreneurship (in a transition context) emphasises the importance of viewing entrepreneurship as a learning process, where entrepreneurs change their behaviour in reaction to changes in their external environment, or in anticipation of this.

In this perspective, entrepreneurship is understood as a non linear process with feedback loops between individuals and their environment. This draws attention not only to the individual component of entrepreneurship, but also to its institutional embeddedness. This emphasises the need for caution when applying entrepreneurship theories and concepts, which have been elaborated in the context of a mature market economy to explain the entrepreneurship phenomenon in situations where the framework conditions for a market economies are still to be established..

## **ABSTRACT**

While the adequate supply of skilled employees for Small and Medium Sized Enterprises (SME) should be a priority, little is known about their awareness of or management of the human resource component of their capacity. There has been significant research and popular press coverage of impending labor shortages affecting large business firms, but not its possible impact on SMEs. Reporting on interview results from 76 small business firms across a variety of industries, this research explores SME perceptions and reactions to the labor shortage issue. Small business firms readily admit to already experiencing such shortages. Their responses are different than what one might anticipate. There is a notable paradox indicating the absence of proactive planning. While the majority of SME firms interviewed have experienced frequent or constant problems finding people with important or firm-survival critical skills, only thirty percent indicate human resource needs and availability processes. We report on the nature of skills sought, and current and anticipated responses to the anticipated shortages. Perceptions of and remedies to the shortage are different than might be expected. This study suggests skill weaknesses, shortsightedness, and naïveté on the part of the small business owners and managers. Considering this as a skill shortage confronting SMEs causes the authors to consider this potentially being more significant than shortages within the external labor market. Although the findings are tentative due to the relatively small sampling of SMEs, they provide encouragement and direction for future research.

## **INTRODUCTION**

Since small businesses represent 99.7 percent of all employer firms in the United States, the impact of small business on the economy and society cannot be overstated. Further, small businesses serve as predictors for the general economic activity of the nation (Dunkelberg, Scott,

Dennis, 2004). The need for those companies to develop and maintain appropriate capacity with which to meet the needs of their customers – customers who range from large original equipment manufacturers (OEMs), to other small and medium businesses (SMEs), and to end consumers – is critical to the success of the general economy. Clearly, a vital component of small business capacity is the collective set of skills, knowledge, and abilities (KSAs) possessed by the firm’s human resources. This paper focuses on that issue.

Given the importance of small business in the U.S. economy, one would suspect that the adequate supply of skilled employees for those firms would be near the top of any list of commercial priorities. Unfortunately, little is known about how well off small businesses really are when it comes to the human resource component of their capacity.

Some of the more obvious specific questions include: Are there significant KSA shortages among small business? What skills are most critical to small business survival and / or mission accomplishment? How aware are small and medium enterprise (SME) managers of KSA shortages that may exist? How do they monitor current and future needs and availabilities? What actions are SME managers willing to take should future shortages emerge? Are KSA acquisition programs formalized? Are they budget lines in company plans? This study aims to address these and related concerns.

## **BACKGROUND**

Although the broad topic of “labor shortage” has long been a mainstay of interest to practitioners and scholars within the human resources management (HRM) field, background themes for the present study serve to emphasize the fact that the impact of any human resource deficit is obviously much broader. At the microeconomic level, adequate labor of the right mix is a cornerstone of company competitiveness. At the macroeconomic level, economic growth of

community (or nation) depends on having access to adequate levels of competent labor.

Fundamental changes in the nature of work itself, however, are serving to amend both local and global notions about what constitutes needed labor and thus what defines “labor shortages.”

SMEs, not unlike larger companies, must develop and implement effective procedures for acquisition and retention of appropriately skilled personnel. The cost to remain competitive can, however, be substantial, particularly for SMEs (*Training and Development*, 2003).

### **Microeconomic Issues**

In a bygone era, tangible items largely defined a firm’s assets, but today’s interest has shifted to intangibles. Human resources create the intellectual capital of an organization, and increasingly, that capital determines the market value of the organization and ultimately its competitive success. As crucial elements of what an organization or firm is capable of providing, employee capabilities as well as shortcomings emerge throughout any company’s managerial dialog. Competitiveness depends on productivity, and productivity depends on how well humans can use the tools of work. As those tools continue to get more complex, higher-level skills must be developed. Increasingly, the objective in HR planning is not labor, rather it is labor with certain critical skills, knowledge, and abilities (KSAs).

When a company faces a shortage of requisite KSAs, something must be done. The company must increase or enhance its recruiting, increase or enhance training of the existing workforce, outsource for needed skills, alter demand patterns for its goods and services (demand management), forego all or some of the operations that depend on the needed KSAs (and thus the ensuing output goods and services that emanate from those operations), or continue to serve customers without having the KSAs that are required. The last option raises serious questions about quality, safety, responsiveness, costs, and workforce fatigue (and other issues). Cessation

of operations can produce direct and immediate revenue decline; demand management can be unpopular because of the short-term disruptions in workflow and potential loss of profitable customer base, and outsourcing has negative short- and long-term effects on local economies and potential long-term effects on company supply lines. That leaves training and / or recruiting – options not totally dissimilar to those in a manufacturer’s make-or-buy decision.

When skills are the sought-after resource, the issues raised in the make-or-buy discussion remain; just the terms and bodies of literature change. Moreover, when the buyer is a smaller firm, the economic consequences of mistakes are exacerbated... company demise can easily be the consequence of inattentive management, whether in manufacturing or in services. Another problem exists in the skills acquisition situation: Need is not always readily apparent. Finally, even if the “right” decision is known, the smaller business owner or manager must typically provide for enhanced training and / or recruiting with minimal staff assistance.

### **Macroeconomic Issues**

The existence of critical KSAs is rapidly becoming a major concern as global competition forces leaders to redefine a country’s wealth. At one time, the key to any nation’s future was its natural resources, but perhaps that time has passed. Today, human resources dominate the assets column in competitive nations. As is the case with global businesses, the quality and number of a nation’s skilled people now determines that country’s likely prosperity or decline (Adler, 1992).

Global and national-level research has historically focused on “labor shortages” rather than on shortages in critical KSAs, but that might be changing. In the United States, concerns about impending labor shortages have been voiced for over a decade (e.g. Johnston, 1992). And not surprisingly, studies generally suggest that labor shortages constrain economic growth (Buss,

1996). A study from the U. S. Chamber of Commerce suggested that the shortage of *skilled* labor is most pronounced in the Midwest (Buss, 1996).

Approximately 70 million U.S. workers from the so-called baby boom will retire, or at least reach retirement age, before 2018 (Sterling and Waite, 1998). This group constitutes about 60 percent of what both employers and economists call the prime-age workforce—that is, people between the ages of 25 and 54. (Kaihla, 2003) Only 40 million new people are expected to enter the workforce during the same period, clearly too few to replace vacated slots, much less fill newly created positions. (Fisher, 2003)

Evidence of worldwide shortages of skilled human resources in certain industries continues to build. In the United States, there is a general consensus among private and public sector analysts that the demand for skilled workers in today's global economy has been outpacing the supply, and that this situation will continue to grow as the millennium continues to evolve. The U.S. Department of Labor has projected that by 2010; U.S. companies will face a shortage of more than 10 million employees (Fisher, 2003). Others have projected that a shortage in the 10-million range will occur several years sooner, perhaps as early as this year (Herriott and Torrey, 2003). Regardless of which prediction is closer, the fundamental message is that the shortage exists and is growing. Shortages of skills could threaten competitiveness, a point that has already been argued in the realm of information technology skills. (Hoffman, 1998)

### **Impact on SMEs**

While the issue of the impending labor shortage has received global press coverage, existing research on the matter is dated (most of it was performed in the early 1990s), and predominately oriented towards larger employers, and focused on the anticipated workforce rather than on the employer. Relatively recent publications still rely on data from over 10 years

ago. While interest in this issue is emerging (e.g., Shane and Knod, 2004; Diebolt and El Murr, 2003,) there has been very little attention focused on Small & Medium Sized Enterprise firms' (SME) skills shortages *per se*. We've been told that there was a surplus from the 1990s through the early half of 2000 (Dundelberg, Scott and Dennis (2004), and that small firms in general will *not* face a shortage (Phillips, 2004), but even that prediction was framed with the recognition that the information is "less than perfect." (ibid.)

Research into the human resource practices of SMEs is limited. There has been some inquiry into the formality of Human Resource processes, and changes to those processes through firm growth. While the processes may become formalized for employees with firm growth, the managers tend to remain informal (Kotey & Slade, 2005; Nguyen & Bryant, 2004). This pattern parallels the research evidence pertaining to SME planning in general. Entrepreneurs and SME managers tend to avoid formal planning (Kern, 2002), preferring informal plans and processes (Penn et al., 1998). Research shows that networking is one method by which SMEs respond to shortages (Sherer, 2003); however, this does not address the shortage, it addresses the migration of workers from one firm to another. Rather than resource development, this reflects a resource hoarding behavior.

Larger organizations are beginning to recognize long-term impacts of KSA shortages, and many have boosted investment in corporate training and management development. Larger companies are more likely to employ a wider variety of external organizations for training than small businesses. Clearly, this trend can have a disproportionate negative impact on small businesses, and therefore, economic development. Though Phillips (2004) argues that overall, small businesses will not experience great labor shortages, he does concede that economic and

demographic changes will create labor shortages in certain industries and in certain parts of the country.

Small firms' source of training is generally an in-house program at the unit or department level. The limited research on small business firms' participation in training initiatives indicates that they do not get involved in external training programs in spite of governmental policy initiatives designed to assist those endeavors. (Devins and Johnson, 2003) According to a recent study conducted by the Research Institute for Small and Emerging Business (RISEbusiness), SMEs utilize handbooks or manuals, and are disappointed with limited access to and affordability of training options (*Training and Development*, 2003).

Small companies have more difficulty filling certain positions than larger firms, and a lack of skilled employees has negatively impacted their businesses in many ways. According to a report from Maryland Business Roundtable for Education (2001), the majority of SMEs so affected have lowered their level of operation and productivity. In short, many of the remedies available to large business firms as they seek to maintain KSAs are not feasible for the small business due to resource constraints. The scope of the present inquiry was intentionally left general, is an attempt to better ascertain the unique SME perspective.

## **METHODOLOGY**

Semi structured interviews were conducted with key senior management and / or ownership personnel from 76 small businesses and entrepreneurships. Fifty-one of the companies operate in the Midwest, specifically in the Mississippi River corridors of Illinois and Iowa. The remaining 25 respondents are located along the Atlantic seaboard in the Eastern Virginia area. Respondents represent 10 diverse industries, with relatively more respondent

concentration in professional services, manufacturing, retail, and construction. Exhibit 1 illustrates participation by industry.

---

Insert Exhibit 1 about here

---

Respondents were asked to identify themselves, state their company positions, indicate the primary industrial classification for their firms, and supply the number of employees in the company. An open-ended item explored how the small business firm was monitoring the labor market. Interviewers were prepared to assist less forthcoming or hesitant respondents to this item with prompts about professional or organizational networks such as trade associations or chambers of commerce, informal networks, information from colleagues, intuition, and so forth. Another open-ended item served to close each interview; respondents were asked if there were any other comments regarding the topic of skills shortages. A Yes / No item indicated whether or not the company had and maintained policies and procedure for preparing *formal* needs and availability budgets for human resources.

The other questions focused more narrowly on respondents' experiences with hiring difficulties, the relative importance of different skill sets for their small business firms, their perception as to whether or not there was a shortage of employees with requisite knowledge, skills, and abilities (KSAs), and on their current and intended future responses to those perceptions. Those items asked respondents to indicate:

- The extent to which the company is currently experiencing shortages of people with specific (named) knowledge, skills, and abilities.

- The extent to which the company relies on each of a (specified list) set of remedies to alleviate any KSA shortage.
- The current importance of each type of skill (from a specific list) to the company.
- The projected or anticipated availability and cost of each type of skill (again, from a list of specific skill types) needed to maintain or increase company capacity for meeting demands.
- The likelihood that, should the company face critical skills shortages, certain remedy options (from a specified list) would be undertaken.

The interviews were conducted by graduate students under the supervision of the principle author (for the Mississippi River corridor), and under the supervision of one of the co-authors (for the Atlantic Coast area). Interviews were scheduled in advance and conducted at a location and time convenient to the interviewee, generally at their places of business and lasting approximately one-half hour.

## **RESULTS**

Results from this exploratory inquiry shed light on several of the research questions noted in the earlier sections of this paper. Additional data are being collected by the authors as part of a long-term study and might certainly cast a different light on these tentative findings. At this juncture, given the limited data set, all analysis has been conducted on the data set as a whole; there has been no attempt, for example, to compare midwestern respondents with east coast respondents. That issue, and related others, will be the subject of another study. Finally, due to the exploratory nature of this research, both qualitative and quantitative interpretations of the interviews provide insight.

### **KSA Shortages in General**

Respondents indicated the degree to which their companies were currently experiencing shortages of people with appropriate knowledge, skills, and abilities with a Likert-type (ordinal) response: Never, rarely, frequently, or constantly. Exhibit 2 shows the frequency of each response and serves as a general overall indicator of the current KSA shortage problem within small businesses.

---

Insert Exhibit 2 about here

---

The fact that 57.9 percent of respondents experience KSA shortages either frequently or constantly suggests that skill shortages are already a real problem for small businesses. Although several respondents identified specific skill shortages (e.g., machining, accounting, marketing), the overall results suggest that shortages are probably more generalized. The authors performed a cross tabulation analysis of the reported degree of shortages (Exhibit 2) with the industry types (Exhibit 1). A chi-square test of independence revealed no support for any relationship between type of industry and KSA shortages ( $X^2$ ,  $df\ 27 = 26.56$ ,  $p = 0.49$ ). Thus, we tentatively conclude that the KSA shortage problem might be expected to affect small businesses across a wide cross variety of industries.

Respondent commentary on the open-ended items provides a rich collection of qualitative data. While personnel from some responding small business firms indicated that they have “no difficulty in finding the people we need” (a comment from a manager at a non-profit agency), or voice a lack of concern because “the union supplies our needs,” there does appear to exist overall anxiety about skills shortages. The concerns are expressed using a variety of words, such as

“critical shortages,” (from a long-term care facility manager), “scarce,” (from an owner of a veterinary / animal hospital), “severe shortage” (from a manager at a trucking company). [The lead author is reminded of a small robotics-welding firm with 50 employees that revised its employee selection process a few years ago. The company abandoned education and experience requirements, and according of the human resources manager, if an applicant was “breathing,” he or she was offered a job.] While it might be easy to consider such a reaction as extreme, the present study suggests that small business firms across a variety of industries are experiencing similar circumstances.

Responses to open-ended questions are replete with comments pertaining to shortages of people with hands-on-skills, deficiencies in critical thinking abilities, and needed interpersonal skills. Somewhat reminiscent of the robotic firm, several of the responding small business firms indicated that they hire people that do not meet qualifications and instead rely on training to instill necessary skills. As one manufacturing firm manager indicated, “We have yet to find anyone in the area with the skill set we need to start off as a contributor.”

Another of the research questions pertains to the nature of skills (or knowledge and abilities) that are deemed “critical for company survival” or at least “important” for the firm’s ability to carry out its mission. Exhibit 3 illustrates the relative degree of importance that respondents attached to a specified list of KSA areas.

---

Insert Exhibit 3 about here

---

Four of the skill areas have been highlighted in Exhibit 3. Over 80 percent of respondents stated that basic communications skills, basic mathematics and quantitative skills, interpersonal leadership skills, and critical thinking skills were either *critical* or *important*. Comparable ratings for strategic skills (58%), information technology skills (42%), and basic science skills (34%) relegated these three categories to a level of somewhat lesser importance in the minds of the respondents.

The skill area labeled “functional” represents a skill that is more or less company or industry specific (e.g., machine tooling, laboratory skills, or patient care), or a more universally needed skill area that was not listed specifically on the survey list but was deemed important or critical by respondents (e.g., marketing, purchasing, or accounting). Most respondents (67 out of 76) did volunteer one or more of these additional functional skills and that information could assist in refinement of future research. Finally, we note that 70 percent of respondents considered one or more of the functional skills to be either *critical for survival* or *important*.

### **Responses to Perceptions of KSA Shortages**

With nearly 60 percent of respondents reporting a frequent or constant KSA shortage, the inquiry shifts to what those companies are currently doing about the shortage, and also what they plan to do about it in the future. The relationships between perceived skills shortages and (1) current responses to those shortages as well as (2) potential future responses to those shortages are somewhat mixed as to the likelihood that a given response activity is being or will be followed.

Respondents were presented with an array of options for dealing with or responding to skills shortages and asked to indicate whether their companies currently used each option *constantly, frequently, rarely, or never*. Ordinal data correlations (Spearman’s  $r_s$ ) between the

degree of shortage experienced (See Exhibit 2) and strength, or intensity, of action on various types of response are summarized in Exhibit 4.

---

Insert Exhibit 4 about here

---

Contents of Exhibit 4 suggest that there is a positive relationship between skills shortages perceptions and efforts to increase training for employees, to recruit both full-time (permanent) employees and part-time (or, temporary) employees, and to engage in overtime and / or extra work shifts. However, there is no significant relationship between the degree of skills shortages perceived and tendency to engage in outsourcing. A tentative explanation might include a general negative opinion of outsourcing *per se* in light of its association with loss of jobs. The very low (4, or 5.3 %) response rate to the “other options” item is evidence that company principals either felt that the listed response options sufficiently covered the scope of their efforts or were unwilling to reveal other steps that they are taking to alleviate shortages.

Respondents were also asked to indicate how their companies might face a future critical skills shortage. Specifically, they were to indicate the likelihood that their firm would engage in any of several possible activities by responding with one of the following choices:

- This is likely to be the preferred option
- We would do this, but we have not yet done so.
- This option would be unlikely.
- My company would not do this.

Ordinal data correlations (Spearman’s  $r_s$ ) between the degree of shortage experienced (See Exhibit 2) and likelihood of action on various types of possible future response are summarized in Exhibit 5.

---

Insert Exhibit 5 about here

---

Exhibit 5 data suggest a very strong positive relationship between the intensity of perceived skills shortages and the likelihood that the firm will work to secure contracts with employees that make extended overtime more feasible. This finding is not surprising given that overtime is among the least risky avenues for short-term capacity enhancement; the existing workforce is knowledgeable, in place, and at least somewhat loyal to the firm. At the same time, this exhausts resource capacity in the long run, and does not enhance sustained human resource capacity. For small business owners, long hours are the norm rather than the exception, so paying employees to work longer hours has a sense of normalcy about it.

Strength of perception of skills shortage is also positively related to the likelihood that the firm will recruit skilled personnel from suppliers and will increase general recruiting that is not targeted to customer or supplier workforce personnel. The option to phase out operations that require needed skills produced interesting results: Fifty-four respondents (71%) said their companies *would not* phase out operations if faced with skills shortages and another 15 (20%) said their firms would be unlikely to do so. Thus, over 90 percent of respondents say they would stay the course and intend to continue providing goods and services even if facing a shortage of the skills necessary to do so.

### **Perceptions Regarding Future KSA Shortages**

Respondents' unwillingness to phase out operations when confronted with critical skills shortages raises several questions, some of which are at least partially addressed by respondents'

open-ended responses. An immediate “reality-check” arises: How do these small business firms envision continued operations without skilled personnel? Several of the companies rely on labor unions to supply workers and don’t appear to have considered the decrease of new entrants into the trades. Other managers or owners admitted to accepting less-than-qualified employees. One must wonder about the resultant impact on the quality, efficiency, and competitiveness of those firms. Several respondents indicated an awareness of impending difficulty, but imply that it is not important to them *now* although company growth may bring KSA shortage into sharper focus.

Throughout the respondent SMEs, there seems to be no great sense of either urgency or acknowledgement of the potential for enduring skills shortages. Some of the respondents do not anticipate growth, and have experienced stability in their current workforces. For those respondents, there is no shortage, and they believe that any cries of impending labor shortages do not apply to them. This might explain why responding SME managers do not anticipate the necessity for drastic steps (such as ceasing certain operations) in current business. Perceptions about the likelihood of being able to acquire each of the types of skills listed in Exhibit 3 were gathered, and summary findings are shown in Exhibits 6 and 7.

---

Insert Exhibit 6 about here

---

Exhibit 6 shows that very few respondents consider any of the types of skills listed in Exhibit 3 as likely to be *impossible* to acquire. Given the exploratory nature of the present study, perhaps any consistency of beliefs concerning ease of future acquisition across skill types may be

assessed appropriately in graphical form. Exhibit 7 contains a bar chart presentation of the data in Exhibit 6.

---

Insert Exhibit 7 about here

---

Exhibit 7 illustrates the rather consistent *collective* agreement among respondents across the eight types of skills for the categories of *readily available with surplus* and *impossible to acquire*. The relative “flatness” of the bar heights for all skill types in these two categories suggest little variation in the number of respondents who believed a particular skill to be either *readily available* (range 10 to 17 respondents; average 12.9), or *impossible to acquire* (range 0 to 4, average 1.4).

There is less consistency among respondents as a group regarding skills that are thought to be in the two intermediate skills acquisition categories, *available at reasonable cost* and *difficult or costly to get*. The first of these categories exhibited the greatest variation (range 27 to 49; average 36.4) in the number of respondents who categorized the difficulty of obtaining a needed skill as available at a reasonable cost. Skills viewed as *difficult or costly to get* exhibited slightly less variation in the number of respondents (range 12 to 37, average 23.3). Critical thinking skills, and to a lesser extent interpersonal leadership skills, were top contenders in the *difficult or costly to get* category, while basic mathematics and quantitative skills followed closely by basic communications skills were the KSA types most often rated as *available at a reasonable cost*.

### **Effects of Formal Budget Processes**

In an effort to gain some (arguably) more tangible insight into just how serious the companies represented by respondents are about acquisition of critical KSAs, a “yes / no” item inquired as to the existence of a *formal* (formality of process was emphasized during interviews) needs and availability budget for human resource needs. The authors hypothesized that having a formalized procedure to analyze small business firm needs and a plan *and budget* for acquisition of critical KSAs would signal a more definitive commitment than merely having a plan to do so. Fifty-two of seventy-four (70%) respondents to this item indicated that their firms did *not* have a formal planning and budgeting process for this purpose in place.

Moreover, the expressed (perceptual) existence of a formal planning and budgeting program does *not* appear to be related to either (1) the degree of company engagement in any of the current efforts (options) to acquire needed skills (Refer to list in Exhibit 4), or to (2) the likelihood of engaging in any of the possible future responses should critical KSA needs arise (See list in Exhibit 5). In other words, when it comes to various techniques for acquiring critical KSAs, respondent small business firms are either “doing” or “not doing” regardless of whether or not the actions can be tied to strategic intent or to specific budget lines.

The finding regarding the (relative lack of) existence of formal budgeting opens the door to a broader issue: When it comes to managing the critical skills component of company capacity, just how sophisticated are small business managers? How well are they performing when it comes to awareness of critical skills needs and in their responses to those needs?

### **Managerial Awareness and Performance**

The principle mechanisms used by respondents to monitor the labor market are their personal and professional networks, including relying on associations, temporary agencies and even competitors for signals of impending shortages. In one sense, relying on networks is

typical behavior for entrepreneurs; on the other hand, depending on others to provide reliable information about a critical resource is contrary to the resource-based view of the firm. Under this framework, any critical resource will be guarded (hoarded) rather than openly shared. Therefore, small business firms that rely on networks to provide signals of impending shortages may get the information late. The timeliness (or lack of it) of the monitoring process is further demonstrated by the number of firms in the present study that indicated their primary labor market indication was response rates to their ads. One could argue that such behavior suggests reactive rather than proactive management.

Another somewhat unexpected hint of managerial weakness (or at least, underperformance) among small business firm owners / operators emerged from the interviews. Several respondents seem to be overly shortsighted, focusing on short-term, operational issues to the exclusion of long-range planning. Moreover, some respondents openly admitted weaknesses in the management of skills acquisition. As one respondent stated, “Only we don’t know what the next step will be.” (From a retail manager) A general review of the interview commentary suggests that small business owner / managers might be insufficiently aware of the managerial KSAs required to perform strategic planning and respond to changing labor market conditions. In short, the small business firms are not aware of what they don’t know. They are focusing predominately on their current situation and not looking into the future.

The short-term or near-term focus can be understood when one considers the operational reality of entrepreneurship and managing an SME. The small business manager is both a productive worker and manager. The nature of entrepreneurship calls for the manager to spend the majority of time with operational issues at the sacrifice of strategic planning. Growth brings new challenges, however, and the skills needed to successfully manage a growing, functionally

structured business are significantly different (Solymossy and Penna, 2001). While previous studies have identified migration of managerial personnel from large business firms to small business firms (Gendron, 1999), the present data provide some indication that the migration might also be between similarly sized and positioned firms. One respondent unabashedly admits to actively recruiting managerial personnel from competitors.

## DISCUSSION

This research, though exploratory in nature, does lend support for the contention that small businesses are indeed facing critical KSA shortages. Moreover, the study data show no evidence that KSA shortage is confined to a particular industry. Our tentative suggestion is that the shortage is widespread among small businesses, perhaps affecting all industry segments. Verification of this dispersion of shortages and investigation of the degree of impact across segments appear to be viable research agendas.

While the original intention was to discover the perceptions of *impending* skill shortages and intended strategies, it is meaningful that the study results suggest (1) that small business firms *are already* experiencing such shortages and readily admit so, and (2) that the responses to current and anticipated (impending) shortages are different than what one might anticipate.

For example, when we consider the issue of a formal planning and budgeting program for acquiring critical KSAs, what appears to be a notable paradox emerges: First, approximately 60 percent of the firms investigated have experienced frequent or constant problems finding people with appropriate skills. Second, depending on the skill area, from 16 to 52 percent of the respondents indicate the likelihood of a skill being either impossible or difficult and costly to acquire. Third, from 34 percent (for basic science) to more than 80 percent (for four of the examined skill areas) of respondents considered the KSA as either critical for company survival

or at least important to the attainment of the company mission. Any one of those three conditions should motivate firms to engage in proactive KSA acquisition planning and budgeting; yet only 30 percent of the responding small business firms do so.

Although 23 responding SME managers do indicate a formal process, the level of sophistication could be questioned. One respondent's notes might be another respondent's formalized plan, since the strategic and managerial processes of entrepreneurs tend to be unique to each entrepreneur's personality (McCarthy, 2003). While McGee and Sawyer (2003) found that the "Perceived Strategic Uncertainty" (PSU) of younger business owners suggest they use more external information than their older counterparts for business planning, evidence continues to indicate that entrepreneurs avoid formal planning (Kern, 2002), preferring informal plans and processes (Penn et al., 1998). Some have even been characterized as "flying by the seat of (their) pants." (Salter, 2004)

The apparent lack of managerial awareness among the current sample of small business firm respondents as to *what one might do in order to alleviate KSA shortages* is of great interest. It suggests that the skill shortage might well rest within the domain of the small business owners and managers; perhaps more significantly than within the labor market itself. Although a shortage of managerial skills in SMEs has been suggested (Higson and Wilson, 1995), it does not appear to have been explored through research.

Responses to the present survey also suggest shortsightedness. While a strong majority of the firms have already experienced critical shortages, they apparently don't equate the skill shortage as having an economic cost to the firm. There seems to be an expression of need for the skills, absent of a willingness to pay for them. Believing that there will be difficulty in

obtaining people with the necessary skills, but believing that they can be acquired at a reasonable cost indicates naiveté.

Another somewhat troubling indication concerns the nature of possible future efforts to acquire the skills necessary for capacity building. The small business firms indicate increasing intensity of current efforts – or what could be expressed as a “try-harder-attitude,” as opposed to a “try-something-new” attitude. In one sense, this demonstrates entrepreneurial tenacity. On the other hand, it is troubling because it appears to contradict the entrepreneurial characteristics of innovative behavior. At what point of time does determination to “stay-the-course” become harmful to the future of the firm?

Regarding the relative importance attached to various skills, some comments are in order. First, an overwhelming proportion of respondents consider basic communications skills, basic mathematics and quantitative skills, interpersonal leadership skills, and critical thinking skills as either critical for survival or important to the company mission. This suggests that these KSA areas are foremost in the minds of small business managers. While there is evidence of a general concern in our society about deficiency in these skills, it is interesting that the small business respondents express far greater concern over these skills than has been demonstrated by previous research with large business firm research. One explanation for this could be that employees of small business firms are expected to perform multiple tasks and multiple functions. Therefore, any weaknesses will have a higher proportionate impact on the firm than might be experienced by a large firm. Even though current respondents placed less importance on basic science, information technology, and strategic skills, relegation of these latter three skill categories to less-than-equal emphasis at this point seems premature.

We note that previous studies (e.g., Haskel & Martin, 2001; Hawley & Raath, 2002) place information technology skills and strategic skills in somewhat higher importance than did the respondents in this study. There are several possible explanations for this difference. The number of employees with the more advanced technological and strategic skills in a small business firm is low; frequently these are the skill sets of the manager or owner of the firm. The small business perspective *might* be acting to downplay these skills in the eyes of respondents. SME firms are niche focused, and *may* not require their employees to demonstrate the depth and breadth of information technology skills sought by large employer respondents of previous research. The matter of whether or not this difference can be generalized to the entire SME community, and if so, investigation of the reasons for any variance from conditions found in larger-companies provide fertile opportunities for further inquiry.

While anticipated shortages of qualified personnel do appear to be real, the effects upon the firm need not be negative. The first step requires recognition of the needs of a growing enterprise. Many of the prescriptive remedies offered by the literature (e.g., increasing pay levels, increasing recruitment efforts and retention rates [Johnston, 1992]) are not as available to SMEs because of their resource constraints. The most significant shortage facing SMEs could well be the lack of a managerial awareness of the knowledge, skills and abilities necessary to grow the firm. The personal attributes and skills used to initiate a venture are different from those that are required to move the organization to a growing, functionally structured enterprise (Solymossy and Penna, 2001).

Entrepreneurs initiate their ventures by creative innovation under conditions of risk. Entrepreneurs must continually manage the growth of their firm with innovative management. Vorhees and Meulenber (2004) conclude that the business owner's level of innovativeness has a

direct impact on firm performance. As demonstrated by some organizations, this can take the form of employee empowerment (e.g. Leonhard Plating Co.), strategic alliances to share resources (Kenton County Airport Board and Cincinnati / Northern Kentucky International Airport), utilization of automation software (e.g. Kendle), tapping alternative labor markets such as stay-at-home mothers (The Payne Firm), or using college students in an internship program (Schafer, 1997).

Drawing on the themes and relationships suggested from this exploration, the authors are developing a general model to guide our subsequent research efforts. Presentation, testing, and discussion of that model, however, are beyond the present scope. Clearly, a major impediment to more thorough analysis in the present study is the limited data set. More powerful parametric and nonparametric statistical analyses must await the growth of the database. Comparisons of critical skills perceptions and responses across industry types, geographical regions, and degree of aggressiveness in seeking needed talent are among the more general types of analyses planned for the future. Future surveys also add the potential for longitudinal studies as well. The present study does highlight, however, the existence of skills shortages and suggest marked differences in perceptions and responses between small business firms and those of previously researched large business firms.

## ABSTRACT

*Recent attempts to guide research on entrepreneurship leave out an important aspect of entrepreneurship, namely its relationship to wealth distribution. Drawing from Schumpeter's work we combine recent research on technical innovation with entrepreneurship research. In doing so, we demonstrate that entrepreneurship, narrowly defined, is a contributing factor towards a more equitable distribution of wealth.*

## INTRODUCTION

*"It is important to note that ... it is not sufficient to know merely the quantities of goods existing in our theoretical country taken as a whole. Not only must the sum of individual wealth be given, but also its distribution among individuals.... The distribution of wealth is important for determining values and shaping production, and it can even be maintained that a country with one and the same amount of general wealth may be rich or poor according to the manner in which that wealth is distributed." - J. A. Schumpeter*

"Entrepreneur" and "entrepreneurship" have become buzzwords both in academia and in the popular press, and have been used in a wide variety of contexts (Shane & Venkataraman, 2000; Schoonhoven & Romanelli, 2001). Interest in entrepreneurship today arises from the recognition that it is an activity that is important for economic growth (Baumol, 1968; Stevenson & Jarillo, 1990). Entrepreneurs and entrepreneurial activity improve competitiveness, create jobs, stimulate the larger economy, and so forth. However, often overlooked in the discussion of entrepreneurship is its role in helping create an equitable distribution of wealth.

In this paper we will investigate the role of the entrepreneur in wealth distribution. First, we will describe the concept of wealth distribution in relation to economic development, in particular how wealth distribution distinguishes economic development from economic growth. We will review the current literature on entrepreneurship, emphasizing the difference between Schumpeter's and Kirzner's theories of entrepreneurship as evident in contemporary views, and in the process develop a definition of entrepreneurship that is suitable for investigating and understanding entrepreneurship as a mechanism for creating and maintaining an equitable distribution of wealth. Third, we will link this definition to, and review the literature on, innovation and technological change, emphasizing on how it relates to wealth distribution. We will use the theories of technological innovation to demonstrate wealth distribution in action and to guide researchers to make a distinction between the entrepreneur's roles in wealth creation and distribution. In doing so, we support a narrower definition of entrepreneurship that excludes some of what is currently labeled as entrepreneurship.

## WEALTH DISTRIBUTION AND ECONOMIC DEVELOPMENT

The gain in social well being within nations is often referred to in a dual statement: "economic growth and development." By this economists mean to draw attention to their two main measures of economic well being - growth in wealth and distribution of wealth. One of Alfred Marshall's motives for developing the neo-classical model was his concern for the inadequacy of wealth distribution evident in the slum sections of England's cities and the misery of the people who lived there (Marshall, 1890: 41). This inequitable distribution of wealth was within the nation with the greatest per capital wealth and the fastest growing wealth in the world at the time. Marshall argued that markets should and could function so as to distribute wealth. Marshall's perfectly competitive markets would adjust prices to equate supply and demand, not just in commodities but also in labor. In his model, markets will adjust prices such that consumers pay fair prices for goods and services; all workers will receive fair wages for their labor; managers will receive fair compensation for their risk taking and organizing of effort; and investors will receive a fair return to their invested funds.

Today, Marshall's tenets form the foundation of the whole field of "general equilibrium theory." But general equilibrium theory has significant weaknesses that are important in this context. First, the model provides no explanation for the process of growth but only for the process of equilibrating markets if and when they grow. Second, the model assumes that generation of new technology is external to the economic system, i.e. not affected by economic factors. Third, it assumes that knowledge is a public good. Finally, there is no room for the innovative entrepreneur since all suppliers offer undifferentiated products and have equal information.

Recent developments in general equilibrium theory, most notably within a field termed "new growth theory" (Solow, 1956, 1957; see Scherer, 1999: for a review) have tried to amend these weaknesses but still there is no role for the entrepreneur in the theory. As Kirzner (1997) persuasively notes, although most economists today agree that markets work, the neo-classical model does not explain how they work (9). He suggests an explanation in which the entrepreneur is a central actor.

Inequitable wealth distribution is the essence of most criticisms of capitalism. Social critics have long considered capitalism to be "unjust" because of the widely differing shares of wealth held by different segments of society. Perhaps the best known critic, Karl Marx (1845), was concerned about the concentration of wealth in the hands of a few under capitalism due to economies of scale. He believed that the largest firms would come to dominate all markets. Perhaps Marx's most important point was that if the distribution of wealth does not meet widespread societal acceptance as a fair, equitable or just phenomena, there will be social unrest and eventually an upheaval (revolution) in the society.

Schumpeter (1942) had similar concerns as Marx, but for different reasons. He argued that economies of scale would not threaten the legitimacy of the capitalist system as long as innovations by new firms (entrepreneurship) bring with them the gale of creative destruction, leading to wealth redistribution. But, he then concluded that large organizations would become more efficient innovators through organized research and development and they would "buy out" potential entrepreneurs. Thus, new independent firms and entrepreneurs (innovators with new independent firms) would cease to exist. Large firm innovation would continue to increase the total output of the economy (growth) but the increasing wealth would be unevenly distributed, eventually undermining the legitimacy of the capitalist system. This in turn leads to the emergence of socialism. Even if this has not happened yet, the greatest challenge today is

demonstrating that the capitalist system is just, fair, and equitable (see, for example, Kirzner, 1997: 71-75) and provides the right institutions for it to remain so.

To date Schumpeter's pessimistic prophecy on the future of capitalism has not come true. The prophecy was based on the assumption that large firms would become much more efficient innovators than entrepreneurs and wealth would become more concentrated thereby requiring emergence of a socialistic system to redistribute wealth. His assumption about the decline of entrepreneurship has been rejected by empirical evidence that has shown small firms are major innovators (Gellman, 1976; Futures Group, 1984). Furthermore, entrepreneurs are important for job creation and economic growth (Birch, 1979, 1987; Kirchoff, 1994). Even if Schumpeter's prognosis on the future of capitalism has turned out to be wrong, his logic on the importance of wealth redistribution for the legitimacy of the capitalist system is still valid. Innovation by new, independent, firms is a mechanism for wealth redistribution. Although the distribution of wealth may change as established firms 'destroy' competitors by means of innovation, this leads to increased concentration of wealth since one large firm gains wealth at the expense of another. Only when innovation is accomplished by newly formed independent firms does wealth become redistributed.

### **WHAT IS AN ENTREPRENEUR?**

As formulated by Richard Cantillon in 1755, entrepreneurs "commit themselves to certain payments in expectation of uncertain receipts, and are therefore essentially risk-bearing directors of production and trade, competition tending to reduce their remuneration to the normal value of their services" (Schumpeter, 1939). Jean-Baptiste Say added the combination of the factors of production (Say, 1836) and Schumpeter qualified this as a 'new combination' (1934: 66, 74). It is currently used to identify individuals who innovate, create new businesses, make decisions, initiate and implement changes or take risk (Schumpeter, 1934: 66).

Shane and Venkataraman (2000), on the one hand and Wennekers and Thurik (1999) on the other attempt to use both the theory and empirical literature to develop a comprehensive definition of entrepreneurship with somewhat different perspectives. Shane and Venkataraman are concerned about establishing entrepreneurship as a research field providing distinctive contributions to the field of business studies. They argue that entrepreneurship involves the discovery, evaluation and exploitation of opportunities by enterprising individuals, unrelated to the setting of that interaction. Wennekers and Thurik, on the other hand, are concerned about the link between entrepreneurship and economic growth. They view entrepreneurship as activities related to perceiving and creating new economic opportunities and exploiting them in the market. These activities are linked to economic growth through the processes of new business creation, innovation and competition. Nevertheless, these theorists do not attend to the link between entrepreneurship and wealth distribution which, according to Schumpeter (1934; 1942) was fundamental to the capitalist system and a condition for its existence.

### **THE CONCEPT OF ENTREPRENEURSHIP**

In their careful review of the economics literature HZbert and Link (1989) identified 12 distinct themes of entrepreneurship. In his survey on how researchers in entrepreneurship, business leaders and politicians define the field of entrepreneurship, (Gartner, 1990) identified 90 different attributes that were mentioned in their definitions. From these exercises it is clear that no universally accepted definition of the phenomenon exists.

The concept nevertheless has a common history within the field of economics traced back to the work of Cantillon (1755). As mentioned before entrepreneurs lost their role in the economic analysis done in neo-classical tradition that became dominant in the early 20th century. In this

tradition resource allocation became the focus and under perfect competition it became merely a routine task by managers who exhibited predictable profit maximization behavior. To many economists this result contradicted the experience of the realities of the economic system that was more lively and less deterministic than pictured by equilibrium theory. Three different schools of the concept of entrepreneurship were constructed as a response to this problem in neo-classical theory (Hřbert & Link, 1989) their most prominent members being Frank Knight, Joseph Schumpeter and Israel Kirzner. Contemporary views are usually related to these three schools, but in different ways.

### ***Knight-Coping with Uncertainty***

Knight's concept of entrepreneurship is based on his distinction between risk defined as measurable uncertainty and uncertainty defined as un-measurable uncertainty. The main difference in the economic sense is that risk is the condition of perfect competition and uncertainty is the source of imperfect competition. Imperfect competition takes many forms and it the primary source of in the capitalist economic system (Knight, 1921: 19-20). In a system of risk that is without uncertainty, which is the perfect competition situation described by neo-classical theory, management of productive resources is merely a routine task. With uncertainty present the primary problem of management is deciding what to do and how to do it. (Knight, 1921: 268). Solving that problem, by selecting and implementing a direction is the core of entrepreneurship according to Knight (1921: 276).

In real life, Knight argues, entrepreneurship is seldom carried out in its pure form, i.e. the entrepreneur is neither owner nor manager of the business. Actual entrepreneurs will in most cases either own part of the business or be the routine manager as well as the entrepreneur. But owners of the productive resources could employ the entrepreneur, and in that case the owners will share the profit and the responsibility (Knight, 1921: 288-290, 299-300). Knight makes no reference to the creation of new business organizations.

### ***Schumpeter - Opportunity Creation***

Although Knight focused on the entrepreneur as an economic agent that directed action in the face of uncertainty, Schumpeter saw the entrepreneur as the agent that changed the economic system from within. According to Schumpeter, neo-classical theory was unable to describe the whole economic process, especially historic change brought about by changes in methods of supplying commodities (Schumpeter, 1939: 46-47, 72). The carrying out of these changes, or innovations, Schumpeter called enterprise. And those who carried them out he called entrepreneurs (Schumpeter, 1934: 77). These innovations competed on the bases of their performance rather than price giving rise to a process of "creative destruction" of existing markets bringing with it an increase in and an equitable distribution of wealth. Entrepreneurs, therefore, create new economic opportunities through innovation.

Schumpeter argued that entrepreneurship necessarily was confined to actions of new firms. He stated that "new combinations are, as a rule, embodied, as it were, in new firms which generally do not arise out of the old ones but start producing beside them" (Schumpeter, 1934: 66). Additionally, "new enterprises are mostly founded by new men and the old businesses sink into insignificance" (136). He nevertheless did see it as possible that innovations could be done within existing firms. He was therefore not consistent on using the entrepreneur and innovator as synonyms; actually, some evolution can be seen in his work on the sources of innovations. In his first book, Schumpeter did not see the entrepreneur's function to "find" or "create" new possibilities upon which to base innovations. These are always present, abundantly accumulated by all sorts of people and generally known (Schumpeter, 1934: 88). Later on he became

concerned that innovation would become a routine activity mastered by existing large firms who created their own sources of innovation through organized R&D and marketing departments. Although innovations by large firms would result in similar effects on the growth of the economy as those by entrepreneurs in new firms, large firms' growing dominance would lead to unacceptable wealth concentration, leading to the emergence of socialism (Schumpeter, 1942: 132-134):.

### ***Kirzner - Opportunity Recognition***

Kirzner criticizes mainstream general equilibrium theory for focusing too much on the equilibrium itself rather than the processes by which equilibrium is attained. According to him markets are constantly in states of disequilibrium and the role of the entrepreneur is to bring economic markets into equilibrium by exploiting the opportunities that arise because of the disequilibrium (Kirzner, 1997: 27-30). Because of uncertainty the entrepreneur does not seize just any 'given' opportunity, but he is discovering and acting on it simultaneously. In fact, to Kirzner, "entrepreneurship becomes reduced to the quality of alertness" (Rothbard, 1985: 281). Part of the discovery is realizing undervalued resources and in the process of doing so the entrepreneur brings markets towards equilibrium. For Kirzner, the innovation process is exogenous to the economic system: "For me the function of the entrepreneur consists not of shifting the curves of cost or of revenues which face him, but of noticing that they have in fact shifted." (Kirzner, 1973: 81). In other words, disequilibrium opportunities are there for the alert entrepreneur to discover and act upon. New technical innovations are exogenous to the economic system in keeping with the general equilibrium model.

Kirzner argues that the entrepreneur has a key role in achieving the efficient allocation of resources in the economy. The entrepreneur makes it possible for equilibrium to be achieved even without perfect information, with product differentiation, and without many competitors. Therefore entrepreneurs have an important function for providing equitable wealth distribution as promised by equilibrating markets. And, they do this while stimulating economic growth (Kirzner, 1997: 7-75). While Schumpeter discards the neoclassical equilibrium model as useless, Kirzner attempts reconciliation with the model. Schumpeter's entrepreneurs create opportunities for innovations by creating new markets, while Kirzner's alert entrepreneurs discover opportunities in existing markets.

### ***Contemporary Views***

Although the concept of entrepreneurship originates from economics, the field of entrepreneurship is currently a multidisciplinary field involving researchers with backgrounds in psychology, sociology, economics and management. The interdisciplinary nature of the field has made it open to different interpretations of the concept of entrepreneurship.

Much of the early work within the entrepreneurship field focused upon the formation and development of independent new ventures (Cooper, Hornaday, & Vesper, 1997). In this tradition Gartner (1988) has defined entrepreneurship as the creation of organizations. Bygrave and Hofer extended that definition to include the identification of opportunities, i.e. the entrepreneur is someone who "perceives an opportunity and creates an organization to pursue it" (1991: 14). Kirchoff has similar focus on the creation of new ventures when he defines entrepreneurship as "the process of (1) identifying an invention worthy of commercialization; (2) converting the invention into a salable product/service; (3) creating or finding a small independent firm to sell the product/service; (4) obtaining the resources to operate the firm and sell the product/service; and (5) successfully operating the firm and generating product/service sales so as to achieve firm survival and growth." (1994: 62).

A number of researchers within the field have emphasized entrepreneurial and innovative behavior of managers, whether in start-ups or established firms. Stevenson (1997) defines entrepreneurship as the "pursuit of opportunity without regard to resources currently controlled" and Shane and Venkataraman define entrepreneurship research as "the scholarly examination of how, by whom, and with what effects opportunities to create future goods and services are discovered, evaluated, and exploited" (2000: 218).

The definitions above relate to Knight, Schumpeter and Kirzner in different ways. The small firm perspective is obviously inspired by Schumpeter but adds the specific aspects of the new organization in a way that Schumpeter did not do. The link is strongest in Kirchoff's definition that is explicitly inspired by Schumpeter. The focus on opportunity recognition is based on Kirzner's view of entrepreneurship and his contribution is clearest in the definition provided by Shane and Venkataraman. Wennekers and Thurik's definition is inspired by Schumpeter's original contribution, but missing his emphasis on the wealth distribution function performed by independent entrepreneurs. Instead their focus is on increase in output. In that context it is natural to include innovation involved in the innovation process, new as well as old. Baumol's definition combines the three of the basic economic perspectives and suggests that they are not incommensurable. He states that the entrepreneur is "incapable to leaving matters where they are" (Baumol, 1993: 11) but faces uncertainty, thereby combining Schumpeter's view on the creative entrepreneur, Kirzner's view of the alert entrepreneur, and Knight's view on the entrepreneur as dealing with uncertainty. This synthesis of the three different schools of entrepreneurship is appealing as it includes both innovation based on disruptive technology and innovation based on evolutionary technology as well as the uncertainty inherent in the innovation process.

Entrepreneurs can create change through innovation and they can respond to change through innovation. However, no attention is given to the effects of the innovation on wealth distribution. We cannot specifically investigate, understand or promote entrepreneurship as a mechanism of wealth redistribution using this definition. We cannot distinguish between the innovations that can redistribute wealth and those that may concentrate wealth. Successful innovation by large, existing, firms may change the wealth distribution but tend to concentrate wealth rather than redistribute it. Wealth redistribution is only possible through new, small independent firms. To identify the link between technical innovation, entrepreneurship and economic development, we have to look at the literature on the economics and management of technical innovation. Much of this literature is built on the foundations laid out by Schumpeter (Becker & Knudsen, 2004).

### **TECHNICAL INNOVATION AND ECONOMIC DEVELOPMENT**

Schumpeter (1939: 46-47) defined technical innovation as the introduction of new combinations of methods for supplying commodities in the economy. According to Schumpeter, entrepreneurs introduce new combinations, i.e. innovations, to the market and enter into competition with existing firms. Unlike Marshall's model, competition is not from equilibrating markets at lower prices, but rather from "...the new commodity, the new technology, the new source of supply, the new type of organization (the largest-scale unit of control for instance) - competition which commands a decisive cost or quality advantage and which strikes not at the margins of the profits and the output of the existing firms but at their foundations and their very lives" (Schumpeter, 1942: 84). In the process the entrepreneur gains a temporary monopoly situation, which transfers market share (and wealth) from existing firms to the entrepreneur.

Schumpeter's description of innovation process is not without critics. Rosenberg (1982) has criticized the distinction that Schumpeter makes between invention and innovation, and between

innovation and imitation or diffusion. Rosenberg sees the innovation process as a continuous process that proceeds in small steps where there are feedbacks and interactions between the steps (Kline & Rosenberg, 1986). Baumol (2002b) focuses on the routinization of this type of innovation in large firms, though he recognizes the importance of innovations by small firms as well (Baumol, 2002a).

Along with the literature on the economics of innovation there has emerged a discipline interested in the management of technology and innovation. The differences between those innovations that have and those that do not have a large impact on society are a major focus of literature in this discipline. Morone (1993), Bower and Christensen (1995) and many others identify two classes of technology: (1) disruptive, radical, emergent or step-function technologies; or alternatively (2) evolutionary, sustaining, incremental or "nuts and bolts" technologies. We will use the terms disruptive and evolutionary.

The definition of disruptive technologies can be found in the strategy categorization scheme developed by Bower and Christensen (1995). They view technologies as two categories and define one as disrupting the current capability set required by a given market. Disruptive technologies are those that do not support current firm based manufacturing or marketing practice. Bower and Christensen note that disruptive technologies may not be "... radically new from a technological point of view" but have superior "performance trajectories" along different critical dimensions that a new set of customers value, but not existing customers (Bower & Christensen, 1995; Christensen, 1997). Abernathy and Clark (1985) focus on capability disruption rather than market disruption. They argue that, due to disruptive technologies' radical newness, robust manufacturing infrastructure does not exist or is very limited. These two viewpoints are not incompatible; in fact the authors recognized that both forms of disruptive technologies exist.

Abernathy and Utterback (1988) confirm this as they describe disruptive technologies as those that create entirely new technology-product-market paradigms that create new to the world markets that may be opaque to customers. There is a clear understanding among these writers that a category of technology exists that serves as the basis for development of innovations that are radically different, are resisted by the existing markets and create entirely new market structures. The activity Schumpeter describes as creative destruction is clearly driven by what these technology theorists call disruptive technologies and discontinuous innovations - radically different, resisted by existing market structures and creating entirely new market structures. Further, the mechanism for overcoming buyer/user resistance to adopting disruptive technologies is the commercialization process that Schumpeter describes as the work of entrepreneurs. Typically, there are no existing markets and new markets for the innovation have not been developed (Abernathy & Utterback, 1988). The entrepreneur must create a commercialization opportunity by pushing the technology upon customers, overcoming their resistance to behavioral change (Moore, 1991). The entrepreneur must demonstrate that the technologies embodied in a new product provide significant cost reductions and/or performance improvements to overcome buyer resistance. In this way, customers are found who are willing to take the risks of newness (Mansfield, 1968).

Evolutionary technologies improve incrementally from a body of existing knowledge (Foster, 1986). Bower and Christensen (1995) describe such technologies as "sustaining technologies," that is technologies that sustain the current manufacturing practices and technological capabilities required in an industrial setting. Evolutionary technologies create innovations that are modifications of, improvements to, or replacements for existing products. These are called

continuous innovations (Morone, 1993). Evolutionary technologies do not alter markets the way that disruptive technologies do as they do not require users to significantly change their behavior. Instead, evolutionary technologies often are driven by customer demand for improvements of existing products; improvements make better products that fit current customer behaviors. Market opportunities for shifting market shares to alternative suppliers arise when customer needs are unmet by existing suppliers in a well defined market structure.

Disruptive technologies create discontinuous innovations that destroy markets. Such discontinuous innovations change the very nature of competition and the overall structure of markets. An example will help illustrate this phenomena. The personal computer changed the entire nature of the computer market. The firms in the market changed; much of their value as operating businesses has been acquired by the start ups who now dominate the market. This truly is an example of Schumpeterian creative destruction. On the other hand, although evolutionary technologies that underlie continuous innovations may shift market shares among competitors, they do not overturn or destroy the markets. They provide improvements of or replacements for existing products. But such continuous innovations have had little impact on determining which firms are in the market, or the way people use a technology. Disruptive technologies and discontinuous innovations logically embody Schumpeter's concept of creative destruction. A disproportionate number of these disruptive technologies emerge from newly formed firms, as Schumpeter believed. New firms are not trapped in an existing stream of evolutionary technology and are free to invent and commercialize for a whole new set of customers. These initiators of discontinuous innovations play a vital role in creating new economic opportunities, and are Schumpeter's entrepreneurs.

### CONCLUSION

We have shown above that the entrepreneur, as a new, independent firm, has a significant role to play in maintaining an equitable distribution of wealth. It is for this reason that we maintain a distinction between the entrepreneurial innovation of a small or startup firm, and the innovative activities of existing, especially dominant, players in the market. It may seem odd that the vitality of the economy is maintained through the decline of large firms, but the continual births of new firms usually more than make up for the lost jobs (Birch, 1987) as well as providing the new blood that keeps the economy going.
