**Research and Development.** The research and development approach to keeping abreast makes the exploration and discovery of new knowledge the primary goal of the activity. The intent is to create the future rather than merely keep abreast of it, in the case of exploratory research. The intent is to test new products and ideas before buying in, in the case of applied research. Elements of this approach include support for applied R&D projects, mechanisms for selecting from among competing R&D proposals, methods for incorporating R&D results into project teams, and staff time and materials to support the R&D effort. The majority of the research observed in this study was of the applied type.

Research and development projects are the least frequently observed of the keeping-abreast approaches in this ISSP sample. Only one ISSP, a large business, had a fully integrated research and development capability. Several of the larger firms have centers for research in business innovation and technology advancement. It is growing more common for these centers to enlist customers as partners in the research. The partners help share the cost of the research in exchange for this participation and early access to the research results. Small firms can participate also, by treating proposal development as a chance for some applied research and development. R&D was one of two approaches (along with technology laboratories) that some ISSPs have tried and rejected on the grounds that it does not provide enough return on investment.

## **LEVELS OF ORGANIZATIONAL COMMITMENT**

A key objective of our research was to analyze the ways in organizations manage their keeping-abreast portfolios. We believed this would reveal patterns that could lead to better understanding of keeping-abreast "best practices." To facilitate this analysis we developed a five-level measure of the degree of resource commitment to the keeping abreast approaches, using existing process maturity models as a starting point. The level of commitment was evident through the degree to which organizational supports – specific goals, objectives, expected outcomes, defined processes, capital investments in equipment and software, recognized organizational status for participants,

and assigned personnel – existed for each approach. Though qualitative, this measure gives a reliable indication of level of commitment, we believe, and provides a means for comparing keeping abreast behaviors among firms and groups of firms, such as the small vs large ISSPs in this study.

Individual keeping abreast approaches were assessed as reflecting an organizational commitment of resources at these five levels:

- *None* No occurrences of approach observed.
- *Ad hoc* Approach exists only temporarily, often in reaction to some external event.
- *Basic* Approach has some continuity and definition, but fairly limited in organizational expectations, structure, personnel, and other resources.
- *Structured* Approach has continuity and permanence. Processes, structures, and expectations have been established and personnel are assigned continuing responsibility for the approach.
- *Integrated* Approach is integrated with the other keeping-abreast approaches through some form of linkages.

These levels were assigned point values ranging from 0 to 4, respectively. This aids in the depiction of patterns of commitment to the various approaches in an organization's portfolio, as will be illustrated below. No proportionality of business value is implied by this point scale.

### **MANAGING THE KEEPING ABREAST PORTFOLIO**

We found that both small and large firm ISSPs commit differing amounts of resources to the various keeping-abreast approaches. In some cases the resources committed ranged widely. Some ISSPs were found to allocate quite modest resources in support of a series of largely independent individual approaches. At the other end of the spectrum, some ISSPs made commitments of millions of dollars and dozens of persons to support a clearly articulated keeping abreast *system*. In general, commitment levels were found to be quite consistent across approaches within any one organization. The case study interviews suggested that at the higher levels of resource commitment the various keeping-abreast approaches support and interact with each other, offering some synergy.

Employing the five-level measure of resource commitment described above for each approach in the portfolio reveals a unique keeping abreast “profile” for each organization studied. This profile represents the way a company manages its keeping abreast portfolio. When this analysis is extended to the classes in the full population -- that is, when the commitment levels for each individual keeping abreast approach are averaged for all small firms and then for all large firms – a comparison of the portfolio management practices of the two defined groups can be made. This is depicted in Figure 1, a radar chart in which the nine radial branches represent individual keeping abreast approaches, and the distance from the origin along each branch represents the average commitment level of the members of the group.

Our research demonstrates that small business ISSPs act quite comprehensively in keeping

abreast, including in their portfolio at least minimally-effective levels of activity in most or all nine of the identified keeping abreast approaches. When averaged as a group, all nine approaches are shown to be supported, albeit to varying degrees. With regard to the averaged portfolio profiles, the small firms mimic the large in shape of their profile, both groups showing quite balanced comprehensive utilization of the nine approaches. The large firms, however, show uniformly higher commitment levels in all nine approaches.

-----  
Figure 1 about here  
\_\_\_\_\_

A number of reasons might explain the noteworthy overall commitment level differences. The fact that the larger ISSPs have more money to spend is immediately obvious. However, the larger firms also have more staff who need to be kept abreast of current developments. In smaller firms there may be more informal communication underway and that may be sufficient to disseminate important keeping-abreast information to those who need to know it. Thus, small firms may need less formal keeping abreast structure than that required by the larger organizations.

The small vs large firm commitment levels are closest in the approaches relied upon most heavily, vendor relationships and the technology gatekeeper. They are also quite close in another important and useful approach, communities of practice/interest. The small vs large firm commitment levels are most divergent in the approaches that are apparently deemed least useful in this industry, internal projects and R&D. This may suggest that small firms marshal their relatively scarce resources and allocate them where they will count the most. The sizable difference in the formal scanning unit, one of the most visible and resource-intensive of the approaches in the portfolio may be a reflection of corporate financial pressures. This approach requires a steady commitment of funds so the resource demand is much less elastic than in other approaches. This makes the formal scanning unit approach more vulnerable to financial pressures that may arise during the ISSP's budgeting processes.

Interestingly, the relatively balanced comprehensive use of all nine approaches by small firms contrasts with the much less balanced and much less comprehensive practice portfolios we found in a companion study. This study includes private and non-profit organizations that provide their ISSP services to internal customers and governmental ISSP organizations, many of which were quite large (Durney and Donnelly, 2005). This suggests that small businesses are efficient in their use of keeping abreast resources, recognizing that by employing the full portfolio of approaches concomitantly they are able to form a dynamic and integrated organizational response to the keeping-abreast challenge in a rapidly changing technological environment.

## **SUMMARY**

Our research revealed that keeping abreast is a dynamic, interactive organizational activity for ISSPs. We determined that nine key approaches were used in the majority of the organizations interviewed, forming what we have called the keeping-abreast portfolio. When commitment levels were measured for each approach in the portfolio, a unique keeping-abreast "profile" was revealed for each organization studied. Of course, each organization's keeping abreast activity is

subject to organizational pressures such as the financial performance, changes in leadership, disruptive technologies, and so on, as for any other organizational activity. Given this dynamic quality, and the fact that these profiles represent snapshots of the keeping-abreast activity at the time the interview was conducted, it is quite possible that these profiles will change over time and not always toward higher levels of commitment.

We believe the results of our research are of value to small and large business ISSPs and other high-technology managers in both small and large organizations who are seeking to improve their organization's success at keeping abreast of rapid change. Our findings regarding the structure of keeping-abreast portfolios provide a useful framework for assessing one's own keeping-abreast activity. While our study focused on the information technology sector, we believe our findings can be reasonably extended to keeping abreast of change in any high tech industry susceptible to rapid technological change. Finally, the portfolio concept is providing a solid foundation for our ongoing research that may determine whether a higher commitment of resources to keeping-abreast activities correlates with greater long-term success for both small and large organizations.

### **Abstract**

This paper explores the literature on the liquidity of the SME globally. The focus of this paper is mainly on Australian SMEs yet the same issues exist in other parts of the world. The UK studies found that poor credit management practices and being undercapitalised are two of the major concerns for small business as they feel powerless to do anything about their debtors' late payments (Chittenden & Bragg, 1997; Peel, Wilson, & Howorth, 2000).

This empirical study is based upon a one period (1997-98) sample from the Australian Bureau of Statistics (ABS) Business Longitudinal Survey (BLS). Regression analyses were undertaken on demographic, owner-manager and financial characteristics to identify the determinants of SME liquidity for Australian businesses. Analyses of the results indicate that financial variables appear to be more important than demographic and owner-manager characteristics. The results from this research needs to be given to SMEs in order for them to understand what characteristics affect their liquidity and how it may vary from industry to industry in which the business operates needs further research.

Peel & Wilson (1996) found that there was a dearth of both theoretical and empirical small business research relating to liquidity issues. The findings of this paper suggest that there is a lot to the liquidity of the SME and legislation should be introduced to remedy the situation. The results of this study have implications for both future research and policy makers into liquidity of the SME.

Keywords: liquidity, small and medium-size enterprises

### **Introduction**

As from 2005 the international accounting standards have implications for the small and medium-sized enterprises (SMEs) to disclosure requirements. The importance of the SME's financial management especially liquidity issues has for sometime been overlooked in some countries with limited research in others (Coleman & Cohn, 1999; Chittenden & Bragg, 1997; (Drever & Hartcher,

2003). Yet in Australia alone there are over one million SMEs employing almost 50 per cent of the workforce making SMEs vital for the economic development.

The methodology is based a one period (1997-98) sample from the Australian Bureau of Statistics (ABS) Business Longitudinal Survey (BLS) that contained 9,732 cases with 724 variables that cover a variety of characteristics. Regression analyses were undertaken on the characteristics to identify the determinants of SME liquidity.

From these preliminary results it suggests that financial characteristics have more relevance than the demographic and owner-manager characteristics. Further research is needed to give owner-managers of SMEs information as to how they can better understand financial management affecting the liquidity of their business. Then investigate further with more research on how liquidity varies from industry to industry in which the business operates is vital for economic growth of SMEs.

Some of the demographic characteristics of an SME for this study include the size of the enterprise by the number of employees, the legal structure, the growth of the enterprise, the age of the enterprise, along with their innovativeness.

Empirical studies commonly use three measures of enterprise size – sales revenues, total employment and total assets (Agarwal, 1979; Barkham, 1994; Casson, 1999; Greiner, 1998). The employment size of micro businesses has changed over the last three decades in the United Kingdom (UK) as with other countries (Osteryoung, 1992; Storey, 1994). By 1991, 10 workers or fewer constituted 92 per cent of all UK enterprises (Storey, 1994).

There are a number of different legal structures but little is known about each structure context. Penrose (1959, 6) suggest that the legal structure sometimes determines the survival of an SME. Bolton Committee (1971,5) noted that the majority of SMEs were not incorporated but were either partnerships or sole traders. Freedman and Godwin found that 40 per cent of limited companies started as a sole proprietorship or as a partnership then moved into a limited company. Choice of the legal structure has implications for the business ranging from the way, in the way it is taxed, to the legal liability of its owner-manager (McMahon, 1995). In Australia, the legal structure of an SME can take the any of the following (Shailer, 1993) sole trader, partnership or proprietary company

Growth of the enterprise has been measured in the literature by the number of employees or sales (Greiner, 1998; Small Business Research Program, 1997). Some economic theorists believe that motivation of the owner-manager has a crucial role in the growth of the enterprise (Casson, 1982; Penrose, 1959; Casson, 1982 #57). Cressy (1999) reports that older owner-managers will have either

no growth or gradual growth since their need to learn in business is smaller and their decisions will respond less to short run news. SMEs' growth and higher exit rates are higher than larger businesses that are older (Small Business Research Program, 1997).

For a business to survive the owner-manager has to meet a number of different challenges relating to growth due to demands on management and business resources (Holmes et al, 2003). Jarvis et al (1996) suggests that owner-managers may be dependent on cash flows for growth and survival of their business. Bianchi & Bivona (2000) report that more a business grows and the perceived current income and cash flows increase, the higher the number of family members' withdrawal requests. Balancing withdrawals and investments to maintain family satisfaction is compatible with business liquidity which is one of the keys to survival and growth of both business and family (Bianchi & Bivona, 2000).

The age of an enterprise or the length of time an SME has been in business is a commonly used demographic so a debate in the literature and debate exists over whether the age of an SME is an important characteristic (Coleman, 2000; Gibson & Cassar, 2002; Greiner, 1998; D. J. Storey, 1994). Storey (1994) found that in the UK and USA younger SMEs grew more rapidly than older enterprises. Coleman (2000) adds the size and age of an SME remains constant with no significant differences between man and females owner-managers. The ABS reports that 56 per cent of newly formed enterprises are expected to cease trading over the following three years. Enterprise survival for the first 10 years without either changing ownership or ceasing is about 45 per cent from the ABS data (Bickerdyke et al, 2000).

Almost any sector in any country could be the breeding ground for entrepreneurs taking risks and introducing innovation into their business (Marsden, 1986; Neck, 1985). The expansion of the service sector began in 1970s and continued through the 1980s enhancing the opportunities for entrepreneurs because economies of scale were less important in that service sector. During the last decade there has been a revival of smallness, entrepreneurship and individual initiative (Davidsson, et al, 1993).

In understanding more about the owner-manager in regard to liquidity is investigated. The gender, educational level, years of experience, their decision-making and whether the business is a family business may impact on the SME are some of the characteristics studied. Owner-managers can be defined as individuals who both own and manage their businesses. Deeks (1976) classified the manager to three positions in a company: whether or not he was an owner of the firm, either as a

shareholder, a partner, or as sole proprietor, whether his responsibilities were general or specialist in character.

Keasey et al (1993, 10) found there is a need for achievement and desire for independence for owner-managers which are fundamental requirements. Those two character traits together might accurately describe an entrepreneur who is also an owner-manager there is no reason to suppose that: a) On average employees in large firms have any less (or more) need for achievement than small firm owner-managers or b) That the need for achievement is particularly strong amongst small firm owners generally. Timmons (1994) found that entrepreneurship involves building a team of people with complementary skills and talents and making sure that the venture does not run out of money when it needs money most. The owner-manager and entrepreneur come together in complex and interrelated ways (Keasey & Watson, 1993, 83) and a clear overlap is evident between entrepreneurship and the SME environment (McMahon et al, 1993).

Research studies on the gender of the owner-manager has been carried out by a number of different countries (Fay & Williams, 1991; Spilling & Berg, 2000; Watson, 2001). Spilling & Berg (2000) claim Norwegian female business manager's account for about seven per cent of total private sector employment, and about five per cent of total turnover. Fay & Williams (1991) reported on the loan manager's view of female business owners in Canada. Cliff (1998) reports on growth, gender and business size of Canadian SMEs. Coleman (2000) conducted an American study into the comparison between male and female-owned firms and the use of financial leverage. Watson (2001) reported from his Australia SME study that failure rates for female controlled businesses are likely to be higher than for male controlled businesses.

There have been a number of research studies on the educational backgrounds of owner-managers in the UK (Hall, 1995, 2000; Robinson & Sexton, 1994). (Deeks, 1976) measured the education undertaken by managers in small furniture enterprises as being the proportion of managers who had attended university. Robinson & Sexton (1994) reports education has a close relationship to entrepreneurship. Dadak (1995) found that there are relatively high levels of education of entrepreneurs in small towns in Bulgaria. Poutziouris et al (1998) claimed that companies run by owner-directors with a university degree, or higher level qualifications exhibit gearing ratios higher than companies run by less formally educated owners. Hall (2000) found that directors of established SMEs who had degrees generally achieved lower rates of growth than those less well educated.

There were a few conflicting surveys on females is educational levels (Cliff, 1998; De Carlo & Lyons, 1979; Welsch & Young, 1984). A greater proportion of non-minority females than minority females reported that they had graduated from both high school and college (De Carlo & Lyons, 1979). The typical female woman entrepreneur emerged as being younger, better educated, more interested in education and more likely to use written information sources than male entrepreneurs (Welsch & Young, 1984). On the other hand, a Canadian study found that females were significantly less likely to possess a business degree (nine per cent of females and 23 per cent of males) (Cliff, 1998).

The more experience the owner-manager has the greater the opportunity to seek out and access finance. There is substantial and growing evidence that SMEs experienced enormous difficulties in raising early-stage capital in the investment range of \$0.5 to \$2.0 million in Australia (Department of Workplace Relations & Small Business, 1998). Hall (2000) found from the UK study that SME owners with little experience at the start-up phase could have problems remaining solvent with an increase in expenditure in relation to their earnings. Storey (1994) suggests that prior business experience did not seem to be a factor to influence the growth of a business.

Differences in participants' managerial and industry experience have been studied (Cliff, 1998; Robinson & Sexton, 1994; Rosa et al, 1994). Rosa (1994) claimed that gender had a significant impact on experience of ownership and management in SMEs. Rosa et al (1994) claims that focusing on separating the complex interaction of gender and other economic forces the shape of business performance. Another study found the effect of education and experience did increase over the span of one's career as the levels of experience increase (Robinson & Sexton, 1994).

A number of financial characteristics to find associations with liquidity are wages expense, interest cost, bank overdraft, creditors, intangible assets, profitability and provisions. Balls (2003) assumes that tens of thousands of SMEs are barely scraping a living. No attempt has been made to measure how many SME households have an income from another source which raises the question about the liquidity of the business. There must be many SMEs operated by one spouse with another in regular waged employment (Balls, 2003).

Garcia (1994) reports that the interest cost can take the bit out of profits and the ability to obtain financing at the drop of a hat could signify life or death to a company today. With the evident of rising interest rates the SME may find itself unable to pay the loan thus affecting the liquidity of the business.

Tax has been an issue for SME for sometime. Little is documented as to how the owner-manager uses the depreciation as a tax shield for the SME. Depreciation in Australia follows the guidelines issued by the Australian Taxation Office. The amount of depreciation can vary depending of the method used. If the SME has a considerable amount of employing assets the tax shield would be high. The deduction than would be high and reduce the amount of tax to be paid.

Storey et al (1987) states that profitability appears to increase with size. Hall (2000) suggests that there is a positive correlation between size of the workforce and profitability. Cooley & Edwards (1983) reported that twenty-seven of seventy-four respondents (36 per cent) ranked the uncertainty of future profitability as the most influential on how much debt was used. There study also found that arranging the responses by business size reveals no significant differences in the relative rankings of the various debt-influencing factors.

Benton (1997) gives an insight as to why bad debts occur. When a company collapses by creating serious implications for those to which it owes money. He found that the issue of repetitive and large bad debt write-offs was an issue and the credit manager had to enforce strategies on a regular basis to minimise bad debt losses.

Burns & Walker (1991) found that 82 per cent of respondents reported having accounts payable with 4.4 per cent reporting accounts receivable which indicates that SMEs in the manufacturing are typically net suppliers of trade credit. Cosh and Hughes (1994) found that current liabilities had a higher proportion of total liabilities for small companies at 33.3 per cent than large companies at 62.4 per cent especially in non-manufacturing. SMEs stretch their accounts payable in order to give themselves extra cash flow liquidity. Venkatesan (1998, 88) found that effective accounts payable can have major strengths by optimises cash flow, reduces interest costs and bridges working capital deficiencies.

Cosh & Hughes (1994) found that for small companies there was a reliance on short-term bank loans and overdrafts than large companies. Poutziouris et al (1998, 13) reported that bank overdraft has remained the major source of external finance in the UK at 45 per cent. Both females and males commonly financed their businesses through overdrafts, but males were significantly more likely to do so (Rosa et al., 1994).

There is no literature to suggest that many SMEs use these accounts to keep their operations liquid. It would be worthwhile to have some information available on what percentage of SMEs had made provisions (annual leave and sick leave) and how it is associated to liquidity of the business.

Previous research suggest men and females have different experiences when attempting to obtain loans (Breen, Calvert, & Oliver, 1995; Coleman, 2000; Fay & Williams, 1991; Rosa et al., 1994). Fay and Williams (1991) reported loan officers were less likely to recommend a loan to a female applicant than they were to a male applicant. The results indicated that gender discrimination might occur in granting loans. Breen et al (1995) found anecdotal evidence that females were discriminated against in the lending process, and were less successful than males in gaining access to business finance. The conclusion is that the females surveyed had no difficulty in obtaining finance where there was a long-standing banking relationship. Coleman's (2000) study demonstrated females owned SMEs had to produce collateral and were not able to access credit the same as males.

Howard (1971) stated that working capital is the lifeblood of the enterprise. Chittenden et al (1998) found from their study that the responsibility for the management of working capital in small businesses goes to the owner-manager. A change in net working capital is the difference between a change in current assets and current liabilities. For a long-term investment, a change in net working capital may arise when acquisition of new equipment results in an expansion of operations (Black, 1993).

## **Methodology**

The data in the ABS BLS utilised for this study investigated the determinants of liquidity in Australian SMEs. The BLS is comprised of data from the 1994-95, 1995-96, 1996-97 and 1997-98 Business Growth and Performance Surveys and for this paper only the 1997-98 period was used.

The BLS data is by far the largest set of data on SMEs that is available at this point in time in Australia. It is also the most comprehensive set of data about the financial characteristics of SMEs that researchers could possibly hope to access and certainly contains a far greater set of data than an independent researcher could hope to obtain. Use of the BLS data also overcomes the constraints and difficulties associated with gathering financial information on businesses. The difficulties associated with obtaining reliable and consistent financial information from businesses has been acknowledged by many researchers and has long been an impediment in the development of any research involving the financial characteristics of businesses (Cassar & Holmes, 2001; Gibson, 2001; McMahon, 2000).

The value of the data in BLS cannot be understated as it provides key data on a large number of SMEs involved in a broad range of different industry activities. In the past a considerable amount of research has reported on relatively small and narrowly defined samples with results that need to be interpreted cautiously and extrapolation to broader populations can be difficult.

The comprehensiveness of the data in the BLS overcomes the disadvantages of a poor response rate that typifies much of the research examining the financial characteristics of businesses because of the compulsory collection of data by the ABS. The testing and evaluation of the data conducted by the ABS prior to its release reduces the need to test for response and non-response bias. Typically, studies attempting to obtain financial information from respondents have very low response rates, which in turn leads to less than optimum outcomes and analyses that need to be interpreted with caution (S. Holmes & Kelly, 1989).

The use of BLS data for the current study reduces the time and costs associated with normal survey work when investigating financial data. Under the Census and Statistics Act 1905 all information enabling the identification of a particular person or organisation must be removed to protect confidentiality. As well, all users of the BLS (or any ABS data) must adhere to strict usage and confidentiality guidelines that form part of the purchase and license agreements.

### **Limitations of the BLS**

The BLS data are still not a complete file covering all SMEs financial data and sets limitations to the analysis in that area until the next time the survey is organised, which is not until 2006. There are a number of missing variables that may have made a significant impact relate to the BLS data. No separate data is available on accounts receivable (debtors) and cash held, sets up a number of limitations that may have created a major impact to the BLS data. To have available separate information on the accounts receivable (debtors) and cash at hand would have expanded this paper into areas that have not been fully researched previously in Australia.

### **Working with the BLS data**

The BLS data contains 724 variables over a broad range that contains material that is not relevant to the current research. The main aim of the study is to determine characteristics of SMEs that predict liquidity. This meant that variables that were considered as to not assist to measure demographic, owner-manager and financial characteristics for this research were removed from the data set. Only 40 variables were maintained from the dataset and some of them were grouped in sets according to small business demographics, owner-manager characteristics and financial characteristics for transformations into ratios of variables and for variables that needed recoding. For simplicity purposes only the period 1997-98 was to be used for this paper's testing. Cases were removed from the data set for the period to be tested because they contained minimal information relating only to the age of the business and gender of the owner-manager.

The ABS made sure the BLS data only contained business having less than 200 employees. In keeping with SMEs the point is made that a number of variables in the data set refer to subsidiaries of parent companies and Gibson’s (2001) study gives reasoning why those cases should be removed. His current research recommends omitting those cases because SMEs with that sort of information would be deemed not as typical SMEs. The cases that were removed were chosen on the basis of the business indicating they had a source of debt or equity from a parent company. It needs to be recognised that these may have precluded some franchisees which could still be ‘typical’ SMEs.

A number of calculations were needed to be carried out prior to data in the BLS being in a format suitable for the analysis of liquidity and its predictors. The transformations required the calculation of ratios. Thomas & Evanson (1987) state ratio analysis is traditionally used to measure liquidity, performance and profitability of a business and to monitor the effectiveness and efficiency of management. The research aims to investigate the relationships among each of these dimensions of the financial characteristics of SMEs. Ratios have been used by a number of researchers to justify their conclusions about financial data.

The calculations and variables used to compute the two measures of liquidity that are to be used as dependent variables in this study. The two measures of liquidity are standard ratios found in any finance textbook (Ross, Thompson, Christensen, Westerfield, & Jordan, 2001; Wilson & Keers, 2003). Calculations used to compute variables to measure liquidity are:

$$NWC \text{ (Net working capital ratio)} = \text{current assets minus current liabilities} / \text{total assets}$$

The following summary of the calculations used to compute values for the independent financial variables. The calculations used to compute each of these variables derived from the prior studies literature. The calculations used to compute the independent demographic variables for the BLS data are:

- SIZE (Employees)* = total employment
- LEG (Structure)* = structure of the business (incorporated or not incorporated)
- GROS (Growth)* = sales turnover for three years/ last year
- GROE (Growth)* = employee turnover for three years/ last year
- AGE (Age of the SME)* = number of years
- INNS (Innovation)* = innovation by service (dummy variable)
- INNP Innovation)* = innovation by product (dummy variable)

The owner-manager variables used in this study using the BLS data are discussed. The independent variables for the owner-manager variables of an SME required for this study from previous studies are as follows:

$$GEN \text{ (Gender)} = \text{male and female (dummy variable)}$$

|                              |   |
|------------------------------|---|
| <i>EDU (Education level)</i> | = secondary, tertiary and degree          |
| <i>EXP (Experience)</i>      | = number of years                         |
| <i>DEC (Decision-making)</i> | = major decision-maker (dummy variable)   |
| <i>FBUS (Family)</i>         | = family decision-making (dummy variable) |

Next the financial variables used in this study using the BLS data are discussed. The independent variables for the demographic variables of an SME required for this study from previous studies are as follows:

|                                |                                       |
|--------------------------------|---------------------------------------|
| <i>BKO (Bank overdraft)</i>    | = bank overdraft/current liabilities  |
| <i>PROM (Profit margin)</i>    | = derived profit/sales turnover       |
| <i>BAD (Bad debt)</i>          | = bad debt written off/total expenses |
| <i>CRED (Creditors)</i>        | = creditors/current liabilities       |
| <i>PROV (Provisions)</i>       | = provisions/current liabilities      |
| <i>WAG (Wages)</i>             | = wages expense/total expenses        |
| <i>TAXS (Tax shield)</i>       | = depreciation/total expenses         |
| <i>IAS (Intangible assets)</i> | = intangible assets/total assets      |

Regression analysis to test the variables discussed above was undertaken by means of employing various independent variables which are regressed against liquidity measures. Each of the independent variables enters the regression equation eleven times, for each of the industry categories. This study is not just considering the different determinants of liquidity for SMEs in Australia but to evaluate the relationships across industries.

## **Results**

Table 1, 2 and 3 shows a significant association between the liquidity model net working capital ratio and a number of independent variables. The independent variables were a number of demographics, owner-managers and the financial characteristics of the SME.

Two demographic characteristic coefficients were statistically significantly different from zero and they were the coefficients for size (number of employees) and age of the SME. No other independent variables for net working ratio liquidity models show any significance.

With the size and age of the SME having a positive result to liquidity is worth mentioning to the owner-manager to must ensure better financial management is undertaken when employing staff and as the business is growing.

Insert Table 1

| Independent variable |                              | Net working<br>Capital ratio  |
|----------------------|------------------------------|-------------------------------|
| SIZE                 | beta<br>[t-statistic]<br>p = | .382<br>24.090<br><b>.000</b> |
| LEG                  | beta<br>[t-statistic]<br>p = | -.011<br>-.682<br>.495        |
| AGE                  | beta<br>[t-statistic]<br>p = | .059<br>3.534<br><b>.000</b>  |
| INNP                 | beta<br>[t-statistic]<br>p = | .002<br>.132<br>.895          |
| INNS                 | beta<br>[t-statistic]<br>p = | -.003<br>-.199<br>.842        |
| GROE                 | beta<br>[t-statistic]<br>p = | .002<br>.133<br>.895          |
| GROS                 | beta<br>[t-statistic]<br>p = | .019<br>1.131<br>.258         |

Table 2 shows there were three owner-manager coefficients that were statistically significant. Educational level coefficient were statistically significant  $p = < .001$ . The family business coefficient showed a significance level of .013. No other independent variables for net working ratio liquidity models show any significance.

It was surprising to learn that the educational level of the owner-manager can have a positive affect the liquidity of the SME. With the negative result for family business towards the SME liquidity is worth monitoring. Understanding the negative aspects of the years experience of the SME with regard to liquidity issues is worth advising the owner-manager.

Insert Table 2

| Independent variable |                              | Net working<br>Capital ratio   |
|----------------------|------------------------------|--------------------------------|
| GEN                  | beta<br>[t-statistic]<br>p = | .007<br>.132<br>.895           |
| EDU                  | beta<br>[t-statistic]<br>p = | .081<br>3.256<br><b>.001</b>   |
| YRE                  | beta<br>[t-statistic]<br>p = | -.034<br>-1.697<br><b>.090</b> |
| DEC                  | beta<br>[t-statistic]        | -0.30<br>-.564                 |

|      |               |             |
|------|---------------|-------------|
|      | p =           | .573        |
| FBUS | beta          | -.039       |
|      | [t-statistic] | -2.485      |
|      | p =           | <b>.013</b> |

Table 3 shows there were financial characteristics for this liquidity model were interest cost, wages expenses and profit margin for the net working capital ratio model which all had coefficients that were statistically significantly different from zero. No other independent variables for net working ratio liquidity models show any significance.

To advise SME that their wage expense does have a negative effect on liquidity and plays an important role in the operating of the business. So too to having interest costs has a positive effect on the SME liquidity. Profit margin has an positive effect on liquidity and needs to be watched by the owner-manager of the SME.

Insert Table 3

| Independent variable |               | Net working Capital ratio |
|----------------------|---------------|---------------------------|
| WAG                  | beta          | -.121                     |

|                      | p =           | <b>.000</b>               |

## Conclusion

Policy makers need to know that there are different sets of independent variables that influence the liquidity of the SME which has not been fully researched. It was disappointing that the liquidity of SME results did not include a number of the financial characteristics such as creditors and bank overdraft. These are two areas requires a considerable amount of research. This research is exploratory but explains some of the issues facing owner-managers.

Further research is needed over a number of industries as there maybe different aspects of liquidity for the owner-manager to be advised on which only is associated to that particular industry.

**Abstract**

The aim of this paper is to determine and compare the influence of certain informal institutional factors upon the decision to become an entrepreneur among men and women entrepreneurs in Spain. To attain this objective we adopt a socio-cultural institutional approach. We undertake a logit model using a robust Spanish dataset from 2003. The main contribution of this paper lies on the identification of specific factors that influence women entrepreneurship, which differ from those of men's. The results show the importance of entrepreneurial self-confidence, as a common factor for both women and men entrepreneurial activity. The main result indicates that the presence of entrepreneurial role models is an important informal institutional factor explaining the difference between women and men's entrepreneurial activity.

**JEL classification:** M13, B52, J16

**Keywords:** Entrepreneurial activity, women entrepreneurship, informal institutional factors.

## 1. PROBLEM STATEMENT

Since the *discovery* of women entrepreneurs by entrepreneurship and small business scholars in the mid 70's (Catley and Hamilton, 1998), research on women's entrepreneurship expanded and matured considerably (Carter et al., 2001). However, there are some *silent areas* in the research on women's entrepreneurship, mostly concerned with how the social world is constructed and how it affects entrepreneurship (Ahl, 2002: 168).

In her extensive literature review on women's entrepreneurship, Ahl (2002) points out that the *typical* study is based on a strong individualistic assumption as it focuses on individuals and their businesses. Women and men are compared by their distinctive entrepreneurial characteristics (e.g. motivations, personality traits, experience) or features of their firms (e.g. size, goals and strategy, management, performance). There are also studies that consider structural factors such as financial constraints or other barriers that women face in the start-up process or development of their businesses. The ways for overcoming such barriers are still suggested at an individual level.

Nevertheless, starting and running a business involves other people such as partners, employees, suppliers, customers etc. It also involves structural and institutional arrangements such as legislation, politics, public services, infra-structure, and business cycles. Turning away the attention from such aspects means the loss of a discussion on the importance of the institutional framework relevant to women's entrepreneurship (Ahl, 2002:166).

The objective of the paper is to determine and compare the influence of the informal institutional factors upon the decision to become an entrepreneur among men and women entrepreneurs in Spain<sup>1</sup>. To reach this objective, we focus the analysis on the socio-cultural and institutional approach.

There have been relatively few investigations focusing on the factors that determine the entrepreneurial activity of men and women from a country perspective (macro level). Recent studies as Arenius and Minniti (2004) or Verheul et al (2004) focused on this issue and used large samples of individuals to compare entrepreneurial activity across countries and the differences and similarities between men and women. Nevertheless, we consider that the results of such direct comparisons between countries should be cautiously interpreted due to the different social and economic contexts in each country (Stevenson and Lundström, 2001). Separate macro level analysis in distinct national settings is also needed, as it may contribute to a better understanding of the differences (if any) between women's and men's entrepreneurial activity and the factors that determine it in each case.

The paper adopts the following structure. Section 2 presents the theoretical framework and the construction of hypotheses. Data and research methodology are introduced in section 3. A discussion of the main findings is offered in section 4. Final conclusions and implications are displayed in section 5.

---

<sup>1</sup> As indicated by García and Jiménez (2004:2), in Spain 26.57% of the enterprises are managed by women, percentage which varies by size, only 16.4% of them, managing business with more than 10 workers, 25.6% managing micro-enterprises and 46.3% being sole entrepreneurs. The authors also indicate that their participation is higher in retail and service sectors.

## 2. THEORETICAL FRAMEWORK AND LITERATURE REVIEW

As indicated in Verheul et al. (2004:4) research on gender and entrepreneurship mainly consists of studies at micro level, focusing on the distinctive characteristics of female and male entrepreneurs such as their motivations to become entrepreneurs, their personality traits, background and experience (e.g. Masters and Meier, 1988; Sexton and Bowman-Upton, 1990; Mroczkowski, 1997; Catley and Hamilton, 1998; Anna et al, 2000). Comparative studies have also been conducted in terms of the features of the firms created by women, capturing aspects such as the size of the firm, the goals, the management style and the strategies adopted by women, or the performance of businesses controlled by women (e.g. Chaganti, 1986; Brush, 1997; Shabbir and Di Gregorio, 1996; Gundry and Welsch, 2001; Watson, 2001; Watson and Robinson, 2003). Other studies have included environmental characteristics, such as financial constraints or other challenges, faced by women at start-up or development of their businesses (e.g. Fabowale et al, 1995; Shabbir and DiGregorio, 1996; Orhan, 2001).

There are relatively few studies that investigate the influence of macro-level factors on female and male entrepreneurship. Exception of this, are investigations as Kovalainen et al (2002); Reynolds et al. (2002); Arenuis and Minniti (2004) and Verheul et al (2004) that use large samples of individuals compare entrepreneurial activity across countries and the differences and similarities between men and women.

Much of the research developed in this field is not theory based (Brush, 1992; Ahl, 2003) and those that are, start either from psychological, managerial or economic frameworks to analyse and compare individual aspects of women entrepreneurs and their businesses.

An alternative approach that a growing number of studies are demonstrating as being more appropriate for the study of entrepreneurship and SME's, is the use of a theoretical framework based on a socio-cultural and institutional approach (Granovetter, 1985; North, 1990; Gnyawali and Fogel, 1994; Maillat, 1996; Urbano and Veciana, 2001; Aponte, 2002; Uhlaner and Thurik, 2004, etc). The main hard-core common to the theories falling under this approach is the basic belief that the decision to create a new enterprise, and therefore to become an entrepreneur, is conditioned by external or environmental factors. In other words, the institutional framework and its socio-cultural factors are what determine the levels of entrepreneurial activity in a specific time and place (Veciana, 1999).

Examples of theories that adopt a socio-cultural or institutional approach have been compiled and described in Veciana (1999). In the mentioned article, the theories under this and the other main approaches used for the study of entrepreneurship are described in much greater length. We will therefore not venture into this task within this paper.

Of the theories within the socio-cultural or institutional approach, the Institutional Economic Theory, developed mainly by Douglass North (1990), is one of the most general, which encloses most of the specificities of the other theories falling under the same approach. The theoretical amplitude that the institutional economic theory offers us is ideal for the objective laid out for this study, and was therefore used as the theoretical backbone guiding our research.

Institutional economic theory develops a very wide concept of “institution”. North (1990: 3) proposes that “institutions are the rules of the game in a society, or more formally, institutions are the constraints that shape human interaction”. Institutions include any form of constraint that human beings devise to shape human interaction. Institutions can be either formal - such as political rules, economic rules and contracts - or informal - such as codes of conduct, attitudes, values, norms of behaviour, and conventions, or rather the culture of a determined society. North attempts to explain how institutions and institutional framework affect economic and social development. The main function of institutions in a society is to reduce uncertainty by establishing a stable structure for human interaction. An exhaustive literature review on the topic of institutional factors that condition new business formation can be found in Rutherford (2001) and Urbano (2003).

According to North (1995), formal institutions are subordinate to informal ones in the sense that they are the deliberate means used to structure the interactions of a society in line with the norms and cultural guidelines that make up its informal institutions. Policy making that attempts to change the formal institutions of society will therefore have little success if it does not first adjust the informal institutions in a compatible way. The difficulty rises from the fact that, whereas a governing body can influence the evolution of a society’s formal institutions in a rather direct way, informal institutions are much less tangible and usually fall outside the direct influence of public policy. They can be moulded, but tend to resist change and take time to evolve towards new social norms.

In the literature on entrepreneurship many different versions of models describing the entrepreneurial process can be found. Models of the entrepreneurial process that consider informal institutional factors as determinants of business creation can be found in Veciana (1988) and Bygrave (1995). Among the fundamental factors affecting the decision to create a business, Veciana’s (1988) model consider informal institutional factors such as the positive examples that make entrepreneurship a more credible alternative; the social attitudes towards entrepreneurship and the non-pecuniary rewards for entrepreneurs. The importance of informal institutional factors also stands-out in Bygrave’s (1995) model. Here, the presence of the entrepreneurial role models is considered as one of the most consistent influential factors, throughout the different stages of the entrepreneurial process.

Very few empirical studies analyse gender and entrepreneurship adopting specifically the institutional economic theory. A rare exception is Nilsson (1997), who investigates the business counselling services directed towards female entrepreneurs in Sweden. Nevertheless, several studies have included variables that can be considered institutional factors in their analysis.

Some of the work produced on gender and entrepreneurship include in the analysis formal institutional factors as, for example, support received by women initiating businesses (Anna et al, 1999), programmes fostering women’s entrepreneurship (Nilsson, 1997; Weeks and Seiler, 2001), the impact that certain governmental policies have on the entrepreneurial activity (Mroczkowski, 1997; Lituchy and Reavly, 2004; Verheul et al., 2004) or the relationships that women entrepreneurs establish with governmental and non-governmental institutions (Mroczkowski, 1997; Fielden and Dawe, 2004; Lituchy and Reavly, 2004).

Research on women's entrepreneurship has given little attention to the analysis of the impact that informal institutional factors may have on the entrepreneurial activity of men and women entrepreneurs. The literature review of studies produced during the past decade, indicate that the fear of entrepreneurial failure and the impact that an entrepreneurial role-model may have on women's decision to start-up, were most investigated within this stream of research.

The fear of failure (usually operationalized through the individual's risk aversion) is a particularly critical issue for entrepreneurs due to the little separation between business and personal risk in an entrepreneurial venture (Watson and Robinson, 2003). Research comparing women entrepreneurs' risk aversion with that of their male counterparts tend to hypothesize that women are more risk averse than men (Buttner and Rosen, 1988; Sexton, 1989; Sexton and Bowman – Upton, 1990; Powell and Ansic, 1997) but there is no agreement yet on this question. However, the social stigma to entrepreneurial failure has been previously investigated on a micro level, but rarely from a macro perspective where the social stigma of failure is analysed.

In their study on Pakistani women entrepreneurs, Shabbir and DiGregorio (1996:516) point out that women in the sample tended to limit their financial risk to their own funds, mainly because they were afraid of the social consequences of business failure, that is, social embarrassment. Fielden and Dawe (2004) obtain similar results of British female entrepreneurs, the social stigma towards the entrepreneurial failure being found as an important barrier to business creation.

Under the light of these findings we expect Spanish female entrepreneurs to perceive the social stigma towards entrepreneurial failure as a barrier to entrepreneurship in a greater extent than their male counterparts. From this argument comes the first hypothesis:

**H1:** Female entrepreneurs are expected to be more negatively influenced by the belief that there is a social stigma towards business failure than their male counterparts.

The Role Model effect on the entrepreneurial activity of women is the second informal institutional factor considered in our analysis. Indirect experience like previous work experience or the experience of others that own businesses is one way of entrepreneurial learning. The role model effect comes from the observation of behaviour in others and can influence substantially how one thinks about entrepreneurship (Reitan, 1997). Role models are persons that by their attitudes, behaviours and actions establish the desirability and credibility of a choice (in this case becoming an entrepreneur) for an individual.

Examples of research on women's entrepreneurship which analyse the role model effect are Lerner et al (1997), Dhaliwal (2000), Levent et al (2003), Arenius and Minniti (2004) or Lituchy and Reavly (2004). In these studies, the presence of a role model for women entrepreneurs was considered as a factor that facilitated their decision to start their businesses. Nevertheless, it is also considered that women, as they historically have been a minority of the entrepreneurial population, lack of close role models or at least, they have less role models than men do (Delmar and Holmquist, 2004: 42).

Hence, in the case of Spanish entrepreneurs we expect similar results, leading to formulate the second hypothesis:

**H2:** The positive influence of entrepreneurial role models on the decision to start-up a new business is greater for men than for women.

The social acceptance of entrepreneurship and business ownership as a valid career option is an informal institutional factor that can affect the perceived attractiveness of becoming an entrepreneur (Hamilton, 2000). The literature on gender and entrepreneurship suggest that entrepreneurship as a career option is gender-blind, studies as Masters and Meier (1998) and Sexton and Bowman-Upton (1990) finding few differences between men and women on this issue. However, we believe that the social acceptance of entrepreneurship as a valid career choice depends on the gender beliefs system existing in a society (country). As argued by Delmar and Holmquist (2004: 33), gender beliefs are cultural schemas representing what we think *most people* believe or accept as true about the categories of *men* and *women*. Also people in general perceive entrepreneurs as masculine and entrepreneurship to be a male domain (Ahl, 2002, 2003). Hence, in most countries, men may be perceived as more *suited* to entrepreneurship than women are. Consequently, the third hypothesis emerges:

**H3:** The influence of the perception of the social acceptance of entrepreneurship as a valid career option upon entrepreneurial activity is greater for men than for women.

Finally, the social praise for entrepreneurs and the social prestige and status that entrepreneurs receive can act as an important non-pecuniary reward for entrepreneurship and therefore affect the opportunity cost of becoming an entrepreneur (Baumol, 1993; Gifford, 1998). We will test whether the belief that the community praises its entrepreneurs is having a positive effect upon entrepreneurial activity and if this effect is the same for women as for men. As argued above, due to the attitudes formed by the traditional gender roles (Delmar and Holmquist, 2004:46), women may be viewed as less entrepreneurial than men and therefore, they may place less value on the social prestige and status they perceive as a reward for their entrepreneurial activity. This leads to formulate the fourth hypothesis:

**H4:** The perception that there are social rewards for entrepreneurs influence women's entrepreneurial activity less than men's.

### 3. DATA AND METHOD

#### 3.1 Data and variables

The data used to carry out this study come from the Spanish Global Entrepreneurship Monitor (GEM) for the year 2003. The original database contained 7000 observations, including 3508 (50.11%) men, and 3492 (49.89%) women. However, in the interest of following a rigorous methodology, only individuals for whom a complete dataset of the independent variables can be constructed are included. Thus, data availability limits the sample to 4877 observations, 2423 (49.68%) men, and 2454 (50.32%) women.

As regards the dependent variable, entrepreneurial activity covers several fields related to business creation, business growth, and innovation strategy. Nevertheless, the meaning used within this study will be the same as that most commonly convened within recent literature, i.e., entrepreneurship as the act of creating a new business. As a result, the dependent variable used in this study as a measure of entrepreneurial activity is the main index resulting from the GEM project, the Total Entrepreneurial Activity index (TEA). This index assumes a value of one if an individual is either involved in “start-up” activities or has recently launched a business (over the last 42 months).

The rationale for the selection of the independent variable set follows. Firstly, to determine the entrepreneur’s profile we consider variables commonly found in many models trying to explain entrepreneurial activity (Usitalo 2001, Douglas and Shepard 2002). Thus, the variables incorporated are the following: age, expressed in years, and; formal education, using dummy variables distinguishing people who finish secondary and those who did not, as well as people with university studies. Furthermore, we consider the self-confidence in one’s own entrepreneurial skills as a dummy variable, assuming a value of one if the person makes a positive assessment of his/her entrepreneurial skills, and zero otherwise. Several studies have recently used this variable in substitution, or together with, formal business training. These studies have found that entrepreneurial self-confidence explains an important part of the decision to become an entrepreneur (Krueger and Brazeal 1994, Arenius and Minniti 2004, Köllinger et al. 2004, Lee et al. 2004).

In addition, a second set of four dummy variables associated with the informal institutional framework have been added to support that the informal socio-cultural environment is an important stimuli, or obstacle, to business creation. These variables are: 1) the social stigma to entrepreneurial failure as an obstacle to business creation; 2) the presence of an entrepreneurial Role-Model, who has created a new business over the past two years within one’s personal social circle; 3) the perception that the community perceives entrepreneurship and subsequently business ownership as a valid career choice; and finally, 4) the perception that entrepreneurship is socially valued and leads to greater social prestige. Table 1 presents the descriptive statistics for the selected variables of the study.

### **Table 1 about here**

As we can see within table 1, there is a highly statistically significant difference between both samples in what refers to entrepreneurial activity. The results show that, in the women sample, the educational level is concentrated in the lower bounds, i.e., women have lower education levels as compared to the men sample. Also, women’s sample shows a statistically significant higher level of social stigma to entrepreneurial failure, as compared to men’s sample. Finally, we report a significant difference in what refers to self – confidence in entrepreneurial skills as well as for our proxy for the Role-Model effect, which result is statistically significant lower in the case of the women sample.

### 3.2 Method

An individual will become an entrepreneur if the total consideration of push and pull factors considered in the analysis results in a positive decision. It is easy and convenient to consider the decision process for becoming an entrepreneur as a process that generates a binary choice model. Thus, to identify the differentiating characteristics that affect the likelihood of women and men to become an entrepreneur, we perform a logit regression model estimated by maximum likelihood method expressed as follows (Greene 1997),

$$\hat{p}_i = p(\text{become an entrepreneur}) = \frac{e^{\hat{b}_0 + \hat{\mathbf{a}}' \hat{b}_n x_{ni}}}{1 + e^{\hat{b}_0 + \hat{\mathbf{a}}' \hat{b}_n x_{ni}}} = L(b'x) \quad [1]$$

Expression [1] may be expressed as a linear function of the odds to turn into an entrepreneur  $\ln \hat{W}_i = \frac{\hat{p}_i}{1 - \hat{p}_i}$ . Thus, after a logarithmic transformation, the resulting expression is,

$$\ln \hat{W}_i = \hat{b}_0 + \sum_{n=1}^N \hat{b}_n x_{ni} + e_i \quad [2]$$

where,

$\hat{b}_0$  = constant term

$\hat{b}_n$  = vector of parameters to be estimated for the  $n$ th independent variables.

$x_{ni}$  = vector of observed value for the  $n$ th independent variables and the  $i$ th cases.

$e_i$  = logistic distributed error term for the  $i$ th cases.

Parameters estimated from the logit model only indicate the direction of the effect of each explanatory variable on the response probability. To obtain a better understanding of the results, we also calculate the probability changes at the sample mean of the regressors by differentiating equation [2] as follows (Greene, 1997):

$$\frac{\partial \hat{p}_i}{\partial x} = \hat{p}_i \hat{\mathbf{a}}' \hat{b}_n \frac{\partial \hat{b}_n}{\partial x} = L(b'x) \cdot \hat{\mathbf{a}}' \cdot L(b'x) \quad [3]$$

Equation [3] applies in the case of individual independent variables. However, in this paper our hypotheses are determined by the influence of the considered informal institutional factors upon women's decision to become entrepreneur, as compared to that of men. We therefore follow Ai and Norton (2003) to estimate robust interaction effects, where for the case of two dummy variables  $(x_1, x_2)$ , the change in the predicted probability that  $y = 1$  results from the discrete double difference with respect to  $x_1$  and  $x_2$ .

Finally, we also calculate the proportion of correctly classified (predicted) observations. This is done for the full sample as well as for those observations that are entrepreneurially active (adopter) and those that are not (non-adopters).

#### 4. EMPIRICAL FINDINGS

The results of the logit models of the binary decision to become an entrepreneur are presented in this section. To corroborate our hypothesis that the informal institutional framework exerts a different influence upon women entrepreneurs, as compared to their male counterparts, we run several specifications where an interactive term between gender and the informal institutional factors is considered individually.

Rather than report the coefficient estimates, table 2 reports the estimated change in the probability to become an entrepreneur. The full set of logit estimates are presented in appendix 1. Model 1 takes into account all the aforementioned variables linked to entrepreneurship. Specifications 2, 3, 4 and 5 have been ran including the interactive terms between gender and the informal institutional factors individually.

The results emerging from table 2 show that, for every specification, the variable linked to the positive valuation of self-confidence in entrepreneurial skills increases the likelihood to become an entrepreneur. For example, the result of model one implies that individuals with entrepreneurial self-confidence are 7.31% more likely to become entrepreneurs, as compared to those who do not. This finding, consistent for every specification, relating the positive influence of entrepreneurial self-confidence and entrepreneurial activity is consistent with previous studies having use similar variables (Arenius and Minniti 2004, Köllinger et al. 2004, Lee et al. 2004).

#### Table 2 about here

Column 2 in table 2 allows for testing our first hypothesis. The findings indicate that both gender and the social stigma towards business failure has a statistically significant negative effect upon entrepreneurial activity. More specifically, the results show that women are 1.53% less likely to become entrepreneurs as compared to men. Also, individuals that perceive the existence of a social stigma towards business failure are 0.98% less likely to get involved in entrepreneurial activities. This latter result is in accordance with those reported in Wagner and Sternberg (2004) and Simon et al. (1999).

The coefficient of the interaction term that relates gender and the social stigma towards business failure shows as no statistically significant<sup>2</sup>. Consequently, we reject the hypothesis 1 that stated that women entrepreneurs are more negatively influenced by their belief in a social stigma towards business failure, than their male counterparts.

The findings in column three indicate that the variable linked to gender remains as statistically significant. In the case of the role model proxy, we find that the personnel

---

<sup>2</sup> The result for the full interaction term varies widely for many observations. However, no observation shows as statistically significant under the conventional levels of acceptance.

knowledge of recent entrepreneurs in individual's social circle increases in 0.71% the likelihood to be involved in entrepreneurial activities. In addition, and consistent with our hypothesis, the interaction term that relates gender to role model indicates that the probability to be entrepreneurially active for women that know an entrepreneurial role model fell 1.56%, as compared to that of men who personally know recent entrepreneurs<sup>3</sup>. This finding is statistically significant, leading to confirm hypothesis two.

The lack of a tradition of positive female entrepreneurial role models may explain this result. This is consistent with Dunn and Holtz-Eakin (1995), Delmar and Gunarsson (2000) and Delmar and Holmquist (2004), who find that the influence of entrepreneurial role models is gender related, an individual being more influenced by another individual of the same sex, as one's aspirations and choices tend to be more influenced by persons of their same sex (Delmar and Holmquist, 2004: 41). Hence, if there has been a lack of positive role models amongst women, or if there mostly have been negative ones, it is comprehensive that, even though women may personally know recent entrepreneurs, they have no influence upon women's decision to become entrepreneurially active.

The results emerging from columns four and five show that gender remains as statistically significant. However, no significant result is found for neither the social acceptance for entrepreneurship nor for the social rewards linked to entrepreneurship. In the case of the interaction terms, none of them indicate that the informal institutional factors have a different impact upon women's decision to become an entrepreneur. These results lead to reject hypotheses three and four; hence neither the social acceptance for entrepreneurship nor the non-pecuniary rewards linked to entrepreneurship exert a different influence on the entrepreneurial activity of women as compared to men<sup>4</sup>.

## 5. CONCLUDING REMARKS

The aim of the present paper was to determine and compare the influence of the informal institutional factors upon the decision to become an entrepreneur among men and women entrepreneurs. Using Global Entrepreneurship Monitor data for Spain we tested a series of hypothesis concerning the impact of informal institutional factors upon female and male entrepreneurship. Adopting a socio-cultural and institutional approach to entrepreneurship, we derived our informal institutional factors as determinants of the entrepreneurial activity of men and women from Veciana's (1988) and Bygrave's (1995) models of the entrepreneurial process.

Our results suggest that Spanish women are less likely to become entrepreneurs as compared to men. Although evidence was found that the existence of a social stigma towards business failure negatively influences the decision to create a business, no significant differences were found between men and women on this issue. Also, no significant differences were found between men and women's propensity to get

---

<sup>3</sup> The result for the full interaction term varies widely for many observations. The statistical significance reported remains for all observed individuals.

<sup>4</sup> In this case, only the result for the full interaction term of social reward varies widely for many observations. As before, no observation shows statistical significance under the conventional levels of acceptance.

involved in entrepreneurial activities as a consequence of their perception of social acceptance and social rewards for entrepreneurship.

Findings in the present paper also indicate that in the case of Spanish entrepreneurs, the personal acquaintance of an entrepreneurial role-model exerts a positive impact on the decision to create a business. Moreover, we found that this positive influence of entrepreneurial role models on the decision to start-up a new business is greater for men than for women. This result has important policy implications, as it indicates that in the case of Spain, entrepreneurial role-models have been a stimulating factor explain a larger proportion of men's entrepreneurial activity than women's. This result is in accordance with that reported in Delmar and Holmquist (2004: 7), confirming that the lack of role-models can act as an obstacle for women's entrepreneurial activities. Therefore, this finding gives further arguments for policy makers to design programmes that foster networking between established and potential women entrepreneurs.

Examples of such practices are the *Advisory Center for Female Enterprise Starters* in Germany, the *Women in Focus* programme in Norway, and the *Women Into the Network Programme* in the U.K., all promoting and offering positive entrepreneurial role-models to women entrepreneurs.

Within the literature on gender and entrepreneurship, the variation in men and women's entrepreneurial activity raised the question of what their determinants are and prompted a series of recent investigations focused on the impact that several factors have on male and female entrepreneurship across countries. While several economic and demographic factors have been previously investigated, the socio-cultural and institutional variables received little attention. Hence, an important contribution of the present paper consists in the insights it offers on the effects that certain informal institutional factors have upon men's and women's decision to create a business.

Moreover, we also believe that the results of direct comparisons between countries should be cautiously interpreted due to the different social and economic contexts in each country (Stevenson and Lundström, 2001). Therefore, an additional contribution of this paper is that it offers a separate macro level analysis in a specific national setting, as it may contribute to a better understanding of the differences (if any) between women's and men's entrepreneurial activity and the factors that determine it in each case.

Values in brackets represent the standard error. Dependent variable: One if the person is identified as being involved in entrepreneurial activity. Women sample size = 2454. Men sample size = 2423. (+)  $\frac{\partial \hat{p}}{\partial x}$  is for discrete change of dummy variable from 0 to 1. Interaction terms are derived as presented in Ai and Norton (2003).

\*, \*\*, \*\*\* = Significant at the 0.10, 0.05, and 0.01 level, respectively.

## **ABSTRACT**

Each era presents new opportunities for entrepreneurs. Some of these opportunities are local, and target the needs of a highly specific and limited market. Others are extensive, offering not only immediate opportunity for market entry and revenue generation, but also the prospect of rapid growth. Such opportunities are not present in every generation, and occasionally entrepreneurial opportunities are not as lucrative as they may appear. The rapid rise of the dot-com business model and its even more rapid crash suggests that any age must be cautious when referring to an entrepreneurial opportunity as a “golden” one. This paper contends that there are three criteria that define a “golden opportunity for entrepreneurship”: 1) There must be a large market; 2) There must be opportunity to create sustainable competitive advantage; and 3) It must be possible to enter the market without aggressive competitive response from incumbents. Based on these criteria, the Micro-Multinational Enterprise (MME) appears to present such a rare golden opportunity for entrepreneurship. An MME is an entrepreneurial venture that leverages foreign or “offshore” labor pools to provide business-to-business services. This practice is referred to as business process outsourcing or “BPO”. The MME that provides BPO-based services to small to medium sized enterprises (SME) meets the three criteria cited as necessary to call an opportunity golden.

## **INTRODUCTION:**

### **DEFINING “GOLDEN OPPORTUNITY”**

Entrepreneurs are nothing if not opportunists. In the midst of some of the most depressing economic conditions, oppressive governing regimes, or personally difficult situations entrepreneurs have been able to turn disadvantages into opportunities. In Lagos, Nigeria, a baker with no capital to speak of and only a modest shop became relatively wealthy by selling sliced

and wrapped bread, which was an advance over traditional vendors who only sold unwrapped bread loaves (Melloan, 2005). A peasant woman in China now operates her own business in Beijing providing expatriates good services and familiar foods from home. Her 2004 sales topped \$3 million (Browne, 2005).

Depending on location, circumstances, and personal resourcefulness, the ingredients of success for entrepreneurs will vary. In the example cited above, only someone who was in the baking business would likely notice the need for individual slices of bread. The person down the street cutting hair for a living would likely not notice the potential of bread-slice market. Was the opportunity a golden one? Perhaps it was. But it was a local event that has little general lessons for entrepreneurs elsewhere. What is required is a definition of golden opportunity that enables an entrepreneur to evaluate whether it is worth the time, energy, and financial commitment to pursue it.

This paper attempts to identify and define a presently live golden opportunity for entrepreneurship. It would be relatively easy and quite commonplace to identify the current golden opportunity as the one that is being pursued by the largest number of new entrants, or the one that attracts the most venture capital, or the one that deploys “cutting edge” technology. Doing so would be understandable, but recent experience suggests this approach may lead to seriously wrong prescriptions. One need look back no further than five years to recognize how simply counting new entrants, following the venture capital, or capitulating to the excitement of new technology can lead to misidentifying a business model as a “golden opportunity” when, in fact, it is no such thing.

To avoid making that prescriptive error—which was made frequently during the height of the dot-com boom—several well-accepted theories of entrepreneurship and innovation are used to analyze a currently prominent entrepreneurial opportunity that appears to be a golden one. In order to achieve the lofty title of being “golden” it seems that the opportunity ought at least to meet the following three criteria:

1. It ought to present a large market;
2. It ought to provide opportunities to create sustainable competitive advantage;
3. It ought to enable market entry with minimal competitive response from incumbents.

This paper set out to determine if there is an opportunity for entrepreneurs in the current global economic environment that meets these three criteria. To prove Criterion 1, I relied upon research that I’ve been conducting over the past two years on the phenomenon of business process outsourcing (BPO). More specifically, I’ve been examining the opportunities that exist for entrepreneurs in leveraging offshore labor pools to establish low-cost, high-quality service offerings (Duening and Click, 2005). Entrepreneurial ventures that use offshore labor to provide services to domestic clients have been referred to as micro-multinational enterprises (MME). The BPO revolution is discussed in some detail in the next section. There, the market potential is explored, and the entrepreneurial opportunity is focused squarely on MMEs providing services to domestic small to medium sized enterprises (SMEs).

Criterion 2 is addressed using the resource-based theory of entrepreneurship. This theory states that entrepreneurs (and entrepreneurial managers in large organizations) are able to create sustainable competitive advantage by leveraging resources that have four characteristics: rare, valuable, hard to copy, and no substitutes. The section discussing the resource-based theory of entrepreneurship examines whether leveraging the resources that have enabled the BPO revolution can provide sustainable competitive advantage.

Criterion 3 is examined from the perspective of the disruptive theory of innovation. This theory states that there are two types of innovation in an economic system: sustaining and disruptive. Incumbents within a market tend to follow a strategy of sustaining innovation, opening up markets of overshot customers who are willing to pay less for offerings that have fewer up-market features. These overshot customers can be acquired using a disruptive innovation strategy. The section on disruptive innovation explores whether the SME market can be entered using a disruptive innovation strategy, minimizing the potential response from incumbents.

## **THE BUSINESS PROCESS OUTSOURCING (BPO) REVOLUTION**

Business process outsourcing (BPO) is defined simply as the movement of business processes from inside the organization to an external service provider. With the global telecommunications infrastructure now well-established and consistently reliable, BPO initiatives often include shifting work to international providers. Five BPO international hot spots have emerged,

although firms from many other countries specialize in various business processes and exporting services (Click & Duening, 2004, p. 10):

1. *India*: Engineering and Technical
2. *China*: Manufacturing and Technical
3. *Mexico*: Manufacturing
4. *United States*: Analysis and Creative
5. *Philippines*: Administrative

Each of these countries has complex economies that span the range of business activity, but from a BPO perspective they have comparative advantages in the specific functions cited.

Because of the job shift that accompanies the quest to employ the highest-value talent, BPO has been both hailed and vilified. Business executives and owners praise it as a way to eliminate business processes that are not part of their organization's core competence. Back-office functions such as payroll and benefits administration, customer service, call center, and technical support are just a few of the processes that organizations of all sizes have been able to outsource to others who specialize in those areas. Removing these functions from their internal operations enables organizations to reduce payroll and other overhead. In an era when executives have been admonished by business commentators and analysts to focus on core competence, BPO offers an opportunity to achieve that goal in a dramatic new way.

Like appliance manufacturers that moved production from the Midwest to Mexican *maquiladoras* or apparel firms that moved production to the Far East, businesses of all types and sizes are now shifting back-office processes and jobs to international locations such as China, India, and the Philippines where the labor is inexpensive and highly skilled. In the past several years, companies have turned to these regions for increasingly sophisticated tasks: financial analysis, software design, tax preparation, and even the creation of content-rich products such as newsletters, PowerPoint presentations, and sales kits (Schwartz, 2003).

With the increasing education levels around the world, BPO is no longer confined to routine manufacturing jobs or boiler-room telemarketing centers. Today's outsourcing involves complex work that requires extensive preparation and training. For example, Indian radiologists now analyze computed tomography (CT) scans and chest X-rays for American patients out of an office park in Bangalore. In the United States, radiologists are among the highest-paid medical specialists, often earning more than \$300,000 per year to evaluate magnetic resonance imaging (MRI), CT scans, and X-rays. In Bangalore, radiologists work for less than half that. Not far from the radiology lab in Bangalore, Ernst & Young has 200 accountants processing U.S. tax returns. Starting pay for an American accountant ranges from \$40,000 to \$50,000; in Bangalore accountants are paid less than half that (Schwartz, 2003).

In the next 15 years, Forrester Research predicts that 3.3 million service jobs will move to countries such as India, Russia, China, and the Philippines. That is the equivalent of 7.5 percent of all jobs in the United States right now (Spain and Coombes, 2003). Estimates from leading

research firms more than support this trend. The Gartner Group, a Stamford, Connecticut–based research firm, predicts that:

- 85 percent of U.S. companies will outsource their human resources (HR) functions in the near future and that revenue from these transactions will exceed \$45 billion in 2003 (Sheahan, 2003).
- One in ten jobs at specialty information technology (IT) firms in the United States will move abroad by 2005, along with one in twenty IT jobs at general businesses—a loss of about 560,000 positions (Gartner Group, 2002).
- BPO will reach \$178 billion in revenues worldwide by 2005, representing a compound annual growth rate of 9.2 percent for the five-year forecast period (Gartner Group, 2002).

Additionally, market research firm IDC predicts that finance and accounting outsourcing will grow to nearly \$65 billion by 2006, up from \$36 billion in 2001. Two-thirds of U.S. banks already outsource one or more functions (Beasley-Murray, 2003).

BPO has managers around the world asking not only what it can do *for* them, but also what it might do *to* them. They are excited about the potential for BPO to help manage costs and improve their balance sheets. Under constant pressure from analysts to control headcount, outsourcing back-office activities to contract laborers in remote corners of the world can provide welcome and quick relief. Whether the labor source is in India, Pakistan, China, or someplace else, the prevalence of high-speed Internet provides opportunities for real-time back-office support regardless of the location of the workers.

At the same time, new questions are emerging and new challenges in organizational design and leadership are arising. Many organizational leaders remain skeptical about BPO because of the lingering after-effects of the tech bubble burst. Their memories are still fresh with images of the change the world mentality of the tech bubble and its alarmingly rapid crash. The thought of investing in new business models right now—especially those with a technology or Internet component—is very difficult for many managers to contemplate.

Many leaders are also concerned about the risks of BPO. They are unsure about the information security issues associated with outsourcing back-office processes. For example, in order for a BPO vendor to assist a client in managing employee benefits the vendor must have access to some of the organization's most sensitive and mission-critical information. The thought of shipping this data overseas to be managed and used by individuals who are not bound by the organization's formal and informal controls is enough to keep a manager awake at night.

BPO is based on the fundamental proposition that organizations should focus on what they do best and outsource everything else. If a company markets and sells sporting goods, it should spend substantially *all* of its time doing that and as little time as possible managing its accounting, customer service, and employee benefits plans. In theory, the concept makes a great deal of sense. In practice, it still seems to invite a new set of challenges that may cost more than the problems it is supposed to solve.

It is critical as well to note that BPO is not a technology or a technology system; it is a business strategy. In that regard, to BPO or not to BPO is a question nearly anyone who manages a

business process must now confront. As a strategic choice, the BPO option is a live one for anyone with a budget, limited resources, and decision rights. For some managers, the decision may even involve the continued existence of their own departments and their jobs. No one is likely to decide to eliminate his or her own job, so managers must learn to understand how BPO may fit into their overall responsibilities and develop the skills to manage the BPO transition and maintain it once it is operational.

Taking advantage of business process outsourcing will be a challenge for managers in all types of organizations and at all levels within those organizations. As we move into an age of greater accountability among organizational leaders, boards of directors, and others with fiduciary responsibility, it is imperative for those leaders to ask whether the firm could perform better by adopting new business models like BPO. Furthermore, as firms within an industry adopt BPO, others will be forced to consider it as the traditional cost structure of their industry comes under pressure.

The competitive and regulatory pressures that will compel managers to take a serious look at their BPO options are only beginning to be felt in some industries. But the revolution is upon us, and its will is relentless. Competitive forces that drive each industry to seek the most effective cost-control measures are irresistible, and no management or organizational structure will be able to hold off the BPO revolution. This means that adoption of BPO is virtually inevitable.

Managers must prepare for the changes that are coming by understanding the factors that go into making a sound BPO decision.

In addition to the basic choice of whether to use BPO a host of technological, business process, and human resource issues follow in the wake of an affirmative decision. The technological issues range from the type of electronic infrastructure that will be required to communicate effectively with BPO partners to the integration of new technologies with legacy systems throughout the organization. These difficult issues require the skillful assembly and management of a team of diversely talented individuals. Because BPO is fundamentally a strategic issue, managers cannot simply call upon their firm's CIO or systems administrators to decide how to achieve an outsourcing relationship. The web of relationships that make up successful BPO initiatives will be based on an array of managerial actions and skills that is unlikely to be present in any single manager or executive.

The competitive and regulatory pressures that will compel managers to take a serious look at their BPO options are only beginning to be felt in some industries. But the revolution is upon us, and its will is relentless. Competitive forces that drive each industry to seek the most effective cost-control measures are irresistible, and no management or organizational structure will be able to hold off the BPO revolution. This means that adoption of BPO is virtually inevitable. Managers must prepare for the coming changes by understanding the factors that go into making a sound BPO decision.

As will be made clear below the complexity of establishing a BPO strategy, the difficulty of finding a reliable offshore vendor, the fear of attendant business risks, and the pressure to find ways to wring costs out of the organization all point to an entrepreneurial opportunity.

Entrepreneurs who recognize that they can leverage global assets to provide and scale outsourced

services to clients will emerge in this BPO revolution. Most likely, it will be the small to medium sized enterprise (SME) that will need third party support from entrepreneurial ventures in initiating and managing an outsourcing project. Entrepreneurs will recognize this opportunity and many are already pursuing it. That the opportunity exists is not in question—what is of moment is whether the opportunity is a golden one.

### **THE RESOURCE-BASED THEORY OF ENTREPRENEURSHIP**

The resource-based theory of entrepreneurship was originally devised to account for the observation that managers within large enterprises often act in an entrepreneurial manner (Barney, 1991). As the term “entrepreneur” does not normally apply to an employee embedded within a large organization, a theory was developed to account for the obvious similarities of outcome for entrepreneurs and entrepreneurial-managers working in large organizations. The resource-based theory states that both of these actors leverage resources at their disposal to develop and sustain competitive advantage.

The resource-based theory of entrepreneurship is particularly useful when attempting to highlight the strategic decisions that entrepreneurs take to establish competitive advantage within an economy (Dollinger, 1999). “Competitive advantage” is a term that has been applied to large firms that have well defined strategic intent and whose primary mode of differentiating from competitors is clear to informed observers. To the established enterprise, competitive advantage is something to be defended. To the entrepreneurial enterprise, competitive advantage is something to be earned. The entrepreneurial achievement of competitive advantage must begin

with an overview of the existing competitive landscape with an eye towards defining niches that can be entered and exploited with minimal response from incumbents.

To establish competitive advantage with existing resources the entrepreneur must find ways to leverage resources that have four fundamental attributes:

- Rare
- Valuable
- Hard to copy
- Have no good substitutes

Under this theory, the entrepreneur is the individual who recognizes and deploys resources that either have these characteristics; or by virtue of their being combined gain these characteristics. In many cases, the entrepreneur is the originator or inventor of the rare, valuable, etc., resource, but not always. It is not imperative that the entrepreneur also be the inventor, patent holder, or behind-the-scenes thinker. The entrepreneur can also be the mobilizer and organizer of resources that appear disconnected or non-combinatorial to others.

In the case of BPO, the entrepreneur is certainly not the originator of the enabling resources—the technologies and social factors—that have precipitated the BPO revolution. In fact, the BPO revolution is not the result of any individual's or nation's specific intent. Business analysts have traced the origin of offshore outsourcing to a September 1989 breakfast meeting in India between then GE CEO Jack Welch and top government advisors (Solomon and Kranhold, p. A1). At the

meeting, Mr. Welch was asked to send some of GE's software development work to India. Recognizing the potential cost savings and other compelling advantages associated with this approach, Welch agreed. Today, India earns more than \$17 billion from companies worldwide who seek its low-cost talent through BPO contracts.

BPO wasn't created by any single individual or nation, but each of its primary drivers was intentionally developed. The six driving factors of BPO are:

1. Educational attainment worldwide
2. Broadband penetration
3. Improved Internet security
4. Near infinite, low-cost data storage
5. Online analytical processing
6. Managerial acceptance of the core competency strategy

The resource-based theory of entrepreneurship does not focus on who created the resource, it focuses on how those resources are organized and deployed. Doing BPO, especially when using an offshore strategy, is exceedingly difficult. Mastering these drivers, leveraging ancillary technologies, and developing the capacity to climb a steep learning curve are potentially sustainable competitive advantages. The difficulty of launching an outsourcing initiative, locating a reliable vendor, mitigating business risk, and controlling the process to produce cost advantages and quality parity are compelling reasons to seek a service provider. The

entrepreneur that learns to bring these disparate resources together and meet customer expectations on one or more business processes can develop sustainable competitive advantage.

For example, Tele-SalesForce (TSF) is a rapidly-growing MME that provides lead-generation services to SME clients across the United States. TSF helps its clients outsource their lead generation processes to a call center in Calcutta, India. In less than one year of operation, TSF has signed up more than 21 clients. TSF has developed a training program for each agent. The program explains the role of lead generator to the agent in terms of stores and manufacturers she is familiar with in India. The TSF project manager describes the business relationships and chemistry, and why is she calling the decision makers of those companies. This education and the resulting conviction in her voice resulted improving from two leads per week to three leads per day.

In addition to TSF's careful training, its call center partner in Calcutta is equally committed to quality performance. A five-year old company, the India call center used the services of Ernst & Young at its founding to ensure that it installed best practices call center technologies and procedures. The firm maintains its quality edge by getting regular audits from E&Y.

Tele-SalesForce is anticipating sales in excess of \$1 million for 2005, with growth projected to reach over \$7 million by 2008. With the risk-mitigation approach the company is taking to call-center outsourcing, it stands a strong chance of meeting and even exceeding its own growth expectations (Duening and Click, 2005).

## **THE DISRUPTION THEORY OF INNOVATION**

One of the most significant challenges facing any entrepreneur or new venture management team is market entry strategy. Rare is the new venture that emerges onto the economic scene into a pristine market not currently being served by incumbent competitors. Quite the contrary, most entrepreneurs find their markets already to be occupied by incumbents who have the dual advantages of brand equity and cash on hand. Entering markets where the opportunities remain great tend to elicit aggressive competitive response from incumbents (Mullins and Walker, 1996).

Rather than going head-on with incumbent competitors, the theory of disruptive innovation suggests that there are market opportunities for new ventures that often can be exploited without provoking intense competitive response. The theory predicts that, as markets mature, incumbents tend to focus energies on high-margin clients. This tends to create a market of “overshot customers” who are less interesting to incumbents and who can be served by new entrants (Christensen, Anthony, and Roth, 2004). Overshot customers are those who are interested in “hiring” the products or services provided by incumbents to solve business problems. However, overshot customers often do not hire the incumbent offerings because they are too expensive, including features that are not necessary, or have a delivery structure not conducive to their business model.

According to Christensen, there are two types of innovation that characterize competitive markets: sustaining innovations and disruptive innovations (Christensen, 2003). Sustaining

innovations are used by incumbent firms to enable them to retain customers for long periods. They are also used by incumbents to maintain their advantage over new entrants in markets that are the most favorable for their business model and that provide the greatest profit margins. Usually, incumbents who rely upon sustaining innovations must continuously move up-market to larger and larger customers as their product's feature set grows and becomes increasingly difficult for smaller customers to afford. Exhibit 1 illustrates these two types of innovation.

-----  
Figure 1 About Here  
-----

Disruptive innovations are used by new entrants who recognize the “innovator’s dilemma” posed by incumbents who must rely on sustaining innovations. Disruptive innovations recognize that there are overshot customers who want to hire the solutions offered by the incumbents, but are not interested in the price or quality features provided. Overshot customers are very willing to pay for a less expensive, lower-quality product to help them achieve the same thing the incumbent product does. Recognizing this as an opportunity, the entrepreneur can exploit the overshot customer market by creating a down-sized version of the incumbent’s products and provide solutions that meet the customer’s less extensive needs.

For example, Kia automobiles entered the highly competitive U.S. market using a disruptive innovation strategy. Kia entered the U.S. automobile market with models that were relatively inexpensive. The features sets on the Kia models were less elaborate than competitor offerings, but good enough for many low-end buyers. Most importantly, Kia avoided the mistakes made by its predecessor at the low-end of the U.S. car market—Yugo. Unlike Yugo, Kia did not target

low-income buyers. Instead, Kia focused on buyers who prefer to economize on automobile spending. This market has substantial disposable income to spend on cars, but prefers to economize on monthly automobile and travel expenses. Included in this market are buyers such as college students and their parents, suburban homeowners who have either no or only a short commute to the office, and lower-middle class buyers who aspire to move up in their income bracket over time.

Kia initially served this overshot market by offering low-price vehicles that had robust feature sets. To distinguish itself from others in this market, Kia created the perception of quality by offering limited warranties that are among the best in the business—100,000 miles or 10 years. The value shopper likes the expensive look of the Kia automobile, the relative peace of mind that is associated with the lengthy warranty, and standard features that include such items as electric windows and door locks, cruise control, and CD players.

Kia's market entry did not draw an aggressive response from the incumbents in the U.S. market. Instead, they ceded the low-end market to Kia, believing that Kia's vehicles would not affect their core business. Of course, Kia had larger aspirations and is now making good on them. Having entered the U.S. market primarily to serve the driving needs of the overshot market, it is now venturing up-market as many customers within the value-shopper category it had originally targeted move up in income bracket. For example, the college students who purchased a Kia as their first vehicle are now seeking more expensive models and are inclined to remain loyal to their original brand.

Overshot customers exist in nearly every competitive market where incumbents have been following a sustaining innovation strategy to grow. Incumbent outsourcing service providers are following primarily a sustaining innovation strategy in their provision of outsourcing services. Their outsourcing services unit is usually an added service to an extensive array of other management and strategic consulting services offered to clients. Because of this, the outsourcing consulting is usually provided using the same model as the firm's other consulting services. Service to the client usually begins with extensive analyses of current state, followed by briefings and recommended actions. Such client services can run into the hundreds of thousands of dollars prior to any outsourcing of business processes.

The large consulting firms that offer outsourcing services typically seek clients that will engage their services beyond the single project. Andersen Consulting, Cognizant Technologies, KPMG Peat-Marwick, and others must sustain high overhead costs and are not interested in single-project, low margin clients. This leaves a wide swath of the market available to entrepreneurs who, like Kia, are interested in quality customers who prefer to economize on spending in a particular area. In this case, the opportunity is BPO services to SMEs. From the perspective of disruptive innovation theory, there is a large set of overshot SME customers who are competing in markets where outsourcing is changing the cost structure for all participants. The SME needs outsourcing support. That is an opportunity for entrepreneurs.

**GOLDEN OPPORTUNITY FOR ENTREPRENEURSHIP:  
THE MICRO-MULTINATIONAL ENTERPRISE (MME)**

Entrepreneurs must leverage resources in new ways to earn competitive advantage in the marketplace. The primary resources at the disposal of the new venture consist of the usual economic factors, including:

- Land
- Labor
- Capital

These resources or factors of production are the most commonly cited ingredients for the production of goods and services within an economic system. More recently, scholars have identified several other important factors that can be leveraged to earn competitive advantage within a system. These include:

- Intellectual capital
- Technology
- Time

Intellectual capital is typically conflated with the term “human capital”, and rightly so. Intelligence, for all of the advances in computing and artificial intelligence, is still primarily resident within the people of an organization. Thus, a rich new source of earned competitive

advantage for entrepreneurs is proprietary or unique access to intelligence (people). Intellectual capital is exceedingly difficult to measure. One effort that gained credence in the late 1990s was referred to as Tobin's Q. This metric examined the net asset value of company and compared it to its market value (market capitalization for public companies). The difference between the net asset value and market value could be attributed, in large measure, to the intellectual capital "owned" by the company. This metric, commonly expressed as a ratio calculated by taking the difference between market value and net asset value and dividing by market value, does provide a useful means of comparing one company's intellectual capital to another's (Villalonga, 2004).

Intellectual capital, expressed as a quantity in the manner of Tobin's Q, will thus be a function of two variables: the quality of the intellectual capital (as measured by the market) and the quantity owned by the company. Increasing either variable increases the Tobin's Q metric for a company. Competitive advantage is gained by leveraging the resources available in an economic system in new ways. Entrepreneurs who seek to enter a market by leveraging intellectual capital can either contract with a highly intelligent person (quality) or with a lot of smart people (quantity). Either approach leverages intellectual capital for competitive advantage.

Technology has played an important role in increasing the productivity of individual workers within organizations of nearly all sizes and within nearly every industry. Today, it would be ludicrous to report for work at a new job only to have the supervisor ask if you will need a computer. Computers in the workplace have become ubiquitous. They have made the transition from providing advantage to those who could afford and deploy them, to a basic tool for conducting business. Since that transition has occurred, various other technological innovations

have been marketed as the next competitive revolution for business. Solution sets that include both software and hardware upgrades and innovations are routinely described as having the potential to help firms separate from the pack or establish competitive advantage.

Most of these marketing messages ring hollow. Technological advances centered on computing, the Internet, or corporate networking are no longer regarded as capable of providing sustainable competitive advantages. The same transition from revolutionary potential to fundamental tool of business characterized the evolution of the use of the telephone, wireless communication, and air travel. Each of these technologies provided brief advantages to early adopters, and then they became fundamental tools that are as basic to good business practice as paying people for a day's work.

Computing, networking, the Internet, and the communications technologies associated with these innovations are now background tools for conducting business (Carr, 2004). Entrepreneurs may find ways to revolutionize computing and networking to develop unique and defensible business models, but that approach bears the risk of rapidly diminishing returns. Moore's Law has held up for several decades, and was aggressively and prosperously leveraged for competitive advantage by firms, such as Intel. But Moore's Law is a physical law, and like all physical laws it speaks not only of possibilities but also of inviolable limitations. If Intel is basing the next ten years of its corporate strategy on Moore's Law it will increasingly become less competitive. The costs associated with manufacturing microprocessors with ever-increasing speed become a limiting factor because the physics (mostly related to heat issues in ever-smaller spaces) are difficult to overcome.

Similarly, the claims by companies such as SAP to have solved the puzzle of enterprise data integration and efficient information flows are growing increasingly stale as company after company struggles to realize the promised advantages. That is not to say that basic computing/networking technologies will not continue to advance and provide incremental advantage—they undoubtedly will. But, the era of disruptive advantages based on computing and networking are likely over.

The technologies that enable global information exchange and communications have become prosaic, but there are golden opportunities that await the entrepreneurs who can now leverage this global infrastructure for competitive advantage. As stated above, one of the factors that make a resource valuable is that it is rare. There is nothing rare about the installed base of fiber optic cables, satellites, and transmission towers that connect the globe to the Internet and wireless networks. However, it is rare within the history of economics that a powerful enabler of commerce is available to everyone at nearly zero cost. Try to think of another enabler of commerce that is available to everyone at little or no cost. Roads, bridges, telephone systems, energy, all have associated costs. The Internet is largely free, and the savvy entrepreneur seeking to establish a venture with global reach can take advantage of tools that enable nearly free communications and virtual work spaces. Some examples of these enablers include:

- Microsoft NetMeeting
- ICQ
- Skype

- FTP Software

Entrepreneurs who learn to leverage these technologies to produce cost structure advantages are likely to be able to sustain this advantage over time. Combining existing technologies to develop operating efficiencies can create disruptive and sustainable advantages just as creating wholly new technologies can do so. New ventures that build and then scale their operations around a unique combination of software and hardware are exceedingly difficult to duplicate. New entries will always be behind the learning curve, and incumbents are usually unable or, at least, find it very difficult to rearrange their current operating structures. Thus, entrepreneurs who focus on leveraging existing technologies in new and novel ways can enter and compete in markets largely unopposed unless they lower their guard and slow their pace of learning.

Finally, the resource of “time” has been recognized as a major factor in the success and failure of ventures. Time has several different meanings, each of which is important in venture development. One connotation of time concerns the speed at which the venture is able to gain access to a market. This is often referred to as “speed to market” or “time to market”. During the dot-com bubble it was widely believed that “first mover advantage” was a predominate factor in the success of an Internet venture. While speed to market remains an important factor, it is now widely recognized that being the “first mover” in many markets is not a critical success factor.

In that regard, time has a second connotation to the new venture, referring to the “moment” and “context” in which a market is entered. This is more commonly referred to as “market timing”. In other words, there is a confluence of factors that, when present, make it more favorable for a

venture to enter a market. The savvy entrepreneur learns to time the venture's market entry to increase the potential for success. Many have observed that market timing is a fool's errand; and that those who attempt to read the signs indicating when it might be appropriate to enter a market are more likely to miss the opportunity than those who randomly enter when they're ready. Nonetheless, it is now accepted that the timing of market entry is a critical factor in a venture's success, whether the timing was intentional or accidental.

The final use of "time" is unique to the advent of a truly global economy. It concerns the notion of a "work day" and the push-pull of economic activity within a closed system. In the United States, for example, the work day largely coincides with the opening and closing of the major stock markets on Wall Street. The majority of large economic transactions occur during this period of time. We may refer to this as the "transaction zone". The transaction zone in any given economic system will have fuzzy margins as most systems will have round-the-clock economic activity (late night restaurants and bars, hotels, gaming facilities, etc.). Still, the concept of a transaction zone is useful because it is that part of the 24-hour daily clock within an economic system where the vast majority of transactions are occurring.

The transaction zone for the global economy has often been characterized as "24/7". That is, it has been said to operate 24 hours per day, seven days per week. While it is true that global economic activity is constant, it is a stretch to conflate this fact with the routines of economic agents acting within a subset of the global system. In other words, while most Americans are aware that economic activity is continuous around the globe, and even though some people actively monitor international bourses through the night, it would be hyperbolic to suggest that

the transaction zone in the U.S. has shifted radically as a result of the growing impact of the global economy.

The Micro-Multinational Enterprise (MME) is a type of venture that leverages these new resources to create rapid and sustainable competitive advantage. The MME leverages the intellectual capital of the global labor pool. Engineers, scientists, MBAs' and many other advanced-degreed individuals are ready and eager to put their talents and skills to work, regardless of where the work comes from.

The MME also takes advantage of the enabling technologies of the BPO revolution, without having to become a "technology company". The MME is not selling a "technology solution" it is leveraging existing technologies to provide services. The worldwide penetration of broadband, especially in outsourcing hot-spots such as India and China, enables the delivery of digitized work processes to nearly anywhere in the world. Another important enabler of the outsourcing revolution is advances in information security technology and policies.

In the past, many ventures were reluctant to conduct business transactions over the Internet or beyond their own four walls because they felt the security risks outweighed the value proposition. However, in today's world of ever-changing technology advancements, most executives are more computer savvy and better understand the security protocols now available. With these new technical breakthroughs, companies can now work within virtual walls with the same level of security they enjoyed within physical walls.

In addition to the security innovations at the technical level, there have been significant changes at the policy and regulatory levels. Most organizations have enacted internal policies to protect sensitive data and information, including institution of security access to physical facilities and requirements for employees to wear identification badges. At the regulatory level, national governments have instituted laws regarding data security. For example, the Indian IT Act of 2000 addresses privacy-related issues and attempts to define *hacking* and *computer evidence*. It also strongly prescribes the implementation of digital signatures and Public Key Infrastructure (PKI) for facilitating secure transactions. The data protection laws enacted by the United Kingdom and the European Union (EU) are considered to be benchmarks in international privacy laws.

The new laws governing data protection, organizational policies, and new technologies have converged to create a highly secure—although still imperfect—communications infrastructure. Although hack-proof systems have yet to be constructed, the ever-more-complex barriers erected to prevent cyber-espionage and cyber-crime make them increasingly less attractive projects for weekend hackers and an expensive undertaking for anyone else.

## **CONCLUSION**

The MME is the golden opportunity for entrepreneurship in the current global economic system. The resource-based theory of entrepreneurship clearly defines the conditions required for developing sustainable competitive advantage. Entrepreneurs launching MMEs are able to leverage global intellectual capital, take advantage of an installed based on enabling

technologies, and provide unique global time-difference advantages to domestic firms that establish a second-shift of operations. Entrepreneurs who are able to establish business processes that provide consistent and reliable quality are rare, valuable, hard to copy, and have few substitutes. This combination of factors is identified by the resource based theory of entrepreneurship as essential to establishing sustainable competitive advantage.

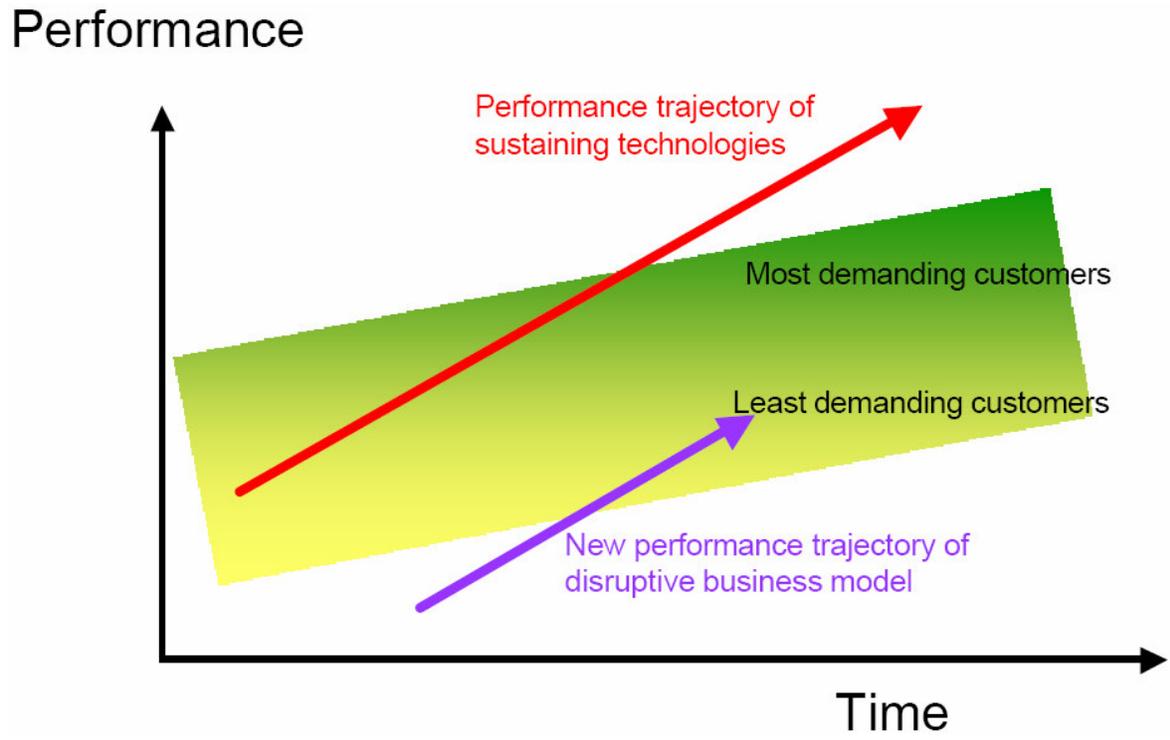

Another critical element in describing an opportunity as Golden is the ability to enter a market without inciting aggressive competitive responses from incumbents. Further, it is imperative that the market entered is large enough to support the growth objectives of the venture. Under the disruption theory of innovation, entrepreneurs can enter overshot customer markets without generating a major competitive response from incumbents. In the case of the MME, the overshot market are the small to medium sized enterprises that want to take advantage of outsourcing, but are unwilling to pay the high prices of the large consulting firms or uncertain about the risks of going it alone. The MME that can unobtrusively and seamlessly integrate an SME's business processes into a BPO model can win rapid market share and sustain it over time. The value proposition that an MME can bring to the SME is almost always compelling and can lead to rapid decisions. With promised savings of 20-30 percent over current costs with no diminution in deliverable quality, the MME can acquire customers rapidly.

As entrepreneurial opportunities go, the MME seems to have the earmarks of a rare golden opportunity. There is little doubt that the outsourcing revolution will continue to grow in the coming years, spreading ever wider into business processes that can be digitized and delivered to the lowest-cost labor pool. By organizing the technologies, management techniques, contracting

nuances, and quality control methods required for successful BPO, the MME that gets a head start in a service category can develop sustainable competitive advantage. Finally, by entering the SME market that is overshot by the large BPO service providers, the MME can anticipate only minimal competitive response as the major players have largely ceded these markets to smaller firms. Combining these factors, and assuming that the three criteria for defining a golden opportunity are correct, the MME business model is currently a golden opportunity for entrepreneurship.

## **AUTHOR AND INSTITUTION PRODUCTIVITY IN THE JOURNAL OF SMALL BUSINESS MANAGEMENT FROM 1994-2003**

### **ABSTRACT**

**This study provides concrete insight into which individuals as well as institutions contributed most to the JSBM during the last ten years. It examines the authorship and institutional affiliations of all the articles appearing in the JSBM from 1994 to 2003 (vol. 32 to 42.) There were a total of 326 articles published with 619 author appearances representing 270 different institutions. Tables show the most prolific authors as well as most represented academic institutions.**

### **INTRODUCTION**

Despite tumultuous changes within higher education in the last few years, the quantity and quality of research output are still of vital importance to an academic career, according to Henthorne, LaTour and Loraas (1998) in a review of advertising scholarship (p. 53). Practitioner author contributions are also vital in providing cross-fertilization of ideas between academics and business.

Following the theme of scholarly applied research, there is little doubt that the Journal of Small Business Management, as one of the senior specialty journals in its field, has bridged the gap between academe and business. As the official journal of the International Council for Small Business and in association with the Small Business Institute Directors Association it has served as the primary reference for those advancing the application of theory and education in a small business context.

Following the precedent of previous ranking studies (Barry 1990; Henthorne, LaTour, and Loraas 1998; Honeycutt and Paul 2004), this study provides concrete insight into which individuals as well as institutions have been heavy contributors to the field of small business management.

### **IMPORTANCE OF ASSESSING A DISCIPLINE'S PRIMARY SPECIALTY JOURNAL OUTPUT**

There is little question of the relevance of research output, both in terms of quantity and quality, to an academic career (Hunt, Neese, and Bashaw 1997). Promotion and tenure, as well as merit pay increases, are constantly tied to research productivity. Today, there is ever-increasing emphasis being placed on teaching and bridge-building to the business community for faculty of business schools since state-funding sources are drying up (Mason 1995).

Many universities that were state-supported are now only state-assisted. This significant reduction in funding has heightened the need to link from academe into industry, and business schools are scrambling to become centers for cutting-edge research dissemination.

There is a growing recognition of the synergistic effects of faculty research programs which bring creative thinking and problem-solving skills to practical business settings and which, in turn, bring real-world relevance into the classroom (Ruch 1995; Shughart 1997). As a result, business school administrations must be sensitive to the evaluation of programs that take research productivity and relevance into consideration.

The need for accountability is at an all-time high for administrators, and evidence must be presented as to the value that has been created by the schools and their faculties and staff in exchange for the operating monies that have been provided (Henthorne, LaTour, and Loraas 1998; Mason 1995). A viable way to accomplish this is the use of productivity studies which reflect knowledge generation and dissemination in high quality journals (Hunt, Neese, and Bashaw 1997; Urban, Wayland, and McDermott 1992).

## **THE STUDY**

This study utilizes the methodology previously employed by Barry (1990), Ford, LaTour, and Henthorne (2001), and Honeycutt and Paul (2004). In this study we examined all of the articles (editorial and peer-reviewed) appearing in the Journal of Small Business Management from 1994 to the end of 2003. The purpose of this study was to examine the authorship and affiliations in the Journal of Small Business Management over the previous ten-year period. We also wanted to examine the total appearances of a particular author.

While we are concerned with recognizing relative individual contributions, it should certainly be noted that co-authorships benefit the discipline through the enhanced perspective on the subject matter provided by multiple authors. There is definitely a synergistic effect that could go beyond the proportional attribution that is accomplished by having multiple authors.

## **RESULTS**

Over the period of the study (1994 through 2003, volume 32 through 41), approximately 32 articles were published annually. There were a total of 326 articles with 619 author appearances, or an average of 1.90 authors per article. The total number of discrete author appearances was 508. Single authored pieces totaled 129, two-authored articles totaled 137, and three-authored articles accounted for 51, while articles with four or more authors contributed the remaining 16.

### **Contribution by Rank**

During the time period covered by our study, approximately 93% of the articles published were submitted by academics. Table 1 indicates that, of that contribution, 25% can be attributed to Assistant Professors. Additionally, Associate Professors were responsible for 23% and Full Professors for approximately 25%. The remaining 20% can be contributed to individuals holding 'other' appointments within the university system.

**[Insert Table 1 about here]**

### **Most Frequent Contributors**

Only 21 authors had three or more appearances over the course of our study. These 21 authors represent only about 4% of total authors who made appearances. More significantly only nine authors had four or more appearances. For each of these nine authors, their total number of appearances, their absolute ranking (based solely on the number of appearances), their adjusted number of appearances (based on partial contribution), and their weighted average ranking are shown in Table 2.

The nine top contributors, in terms of total appearances, were Dana (15 appearances), Miller (5), Morris (5), Castrogiovanni (4), Deshpande (4), Hornsby (4), Kuratko (4), Mathews (4), and Van Auken (4). When co-authorship was taken into consideration, this ranking changed substantially, with Dana maintaining his original position. Van Auken moves into 2<sup>nd</sup> position, while positions three through five were taken by authors with less than four total appearances. Associatively, it can be seen that Miller, Morris, and Deshpande all drop to a tie for 6<sup>th</sup> position. It should be noted that these results make no distinction between peer and editorially reviewed articles. During this ten year period about 60 percent of the articles published in the JSBM were peer reviewed.

**[Insert Table 2 here]**

### **Institutional Affiliations of Contributors**

The institutional affiliations for contributors may be found in Table 3. As before, the appearances are listed along with the absolute rankings (based on total appearances), the adjusted number of appearances (based on partial contribution), and weighted average. The top seven schools, in terms of total appearances, were Iowa State (17 appearances), McGill (15), Ball State (14), and Western Michigan (10). Again, we see the rankings change somewhat when looking at weighted averages. When fractional contribution is included, Iowa State drops to 2<sup>nd</sup> position, while McGill moves into the number one spot. Table 3 highlights the institutional rankings and changes due to fractional contribution.

**[Insert Table 3 about here]**

## **DISCUSSION AND CONCLUSIONS**

The primary purpose of the Journal of Small Business Management is to publish quality research articles in the fields of small business and entrepreneurship from around the world. It has been recognized as a premier journal by academics and business leaders for many years and this review of articles published from 1994 through 2003 verified the global reach of the JSBM.

Authors from every continent and dozens of countries solidified the JSBM's claim to be one of the world's preeminent small firm research periodicals.

This study provides a benchmark for assessing the academic output of both individuals and institutions relative to the field of small business. This kind of benchmark gives some concrete evidence of the type of scholarship necessary for both individuals and institutions. The absolute number of total contributors (508 different authors) and institutions (over 275 from around the world) indicate that the JSBM is truly representative of the International Council for Small Business.

As with any study, there are a several limitations which must be noted. First, since the JSBM publishes both peer reviewed and editorially reviewed articles (at least it did during the time period examined) some could make an argument that not all articles should be considered equal. However, since the number of editorial reviewed articles was so large (121 versus 205) we chose to simply count them all. Further research could distinguish between them. Another limitation is that we did not do any analysis of the subsequent impact of the published articles through some form of citation tracking. This could also prove useful. Another limitation to the university affiliation ranking is that we did not do any analysis of the relative size of institutions. This could alter the relative contributions if taken into consideration. While these are serious limitations, hopefully this research has given some insight into the publishing trends and output efforts of small business researchers.

## **ABSTRACT**

Our recent survey of the existing family business literature was prompted by rising community interest in family business succession planning. The resulting report shows that much useful and interesting information on this topic has accumulated in recent years and research continues. However, the reality remains that despite having gathered significant amounts of information on many specific factors, processes and relationships that affect succession planning, there are still numerous areas which require further exploration. Little work appears to have been done to more fully explore the function of personal and social dynamics in succession planning and the manner in which the web of relationships in family business impact upon both individual and business behaviour. Others have also recently noted that there has been limited exploration of both the social and business context surrounding family business succession. In this paper we argue that, in order to make significant advances in understanding this subject, more needs to be done to understand succession planning from the perspective of relationships. Moreover, we suggest that employing social capital as a conceptual tool offers one method of proceeding with this task and we offer examples illustrating its potential. By adopting such an alternative lens of analysis we hope that family business researchers can extend their knowledge in a manner that lends insight into business conduct more broadly.

## **INTRODUCTION**

In the Australian business community there is a rising interest in information about succession and how it can be effectively planned. This awareness results from the increasing age of business owners and that a growing number of businesses can expect to undergo some form of ownership or management transfer in the near future. A wide ranging survey of the existing literature (Dunemann and Barrett, 2004) ascertained that given succession planning has been a core concern of family business research since its inception, there is abundant relevant material. The resulting report (Dunemann and Barrett, 2004) documented the many factors, processes and relationships which influence succession planning along with several succession planning models.

Arising out of this process was an acknowledgement of the great value of the existing research on this matter, yet also a strong sense that important gaps in our knowledge and research focus need to be addressed. It is clearly evident that more emphasis needs to be placed upon the difficult to examine 'human' factors in succession planning. Indeed, we should focus more of our research emphasis upon the ways relationships, personal and social dynamics, and the overall context surrounding family businesses influence succession planning (Dunemann and Barrett, 2004: 40). Recognition of the need to more seriously address these aspects of family business and succession planning is evident in recent research (Le Breton-Miller, Miller and Steier, 2004; Sharma, 2004; Zahra and Sharma, 2004).

Following Fox, Nilakant and Hamilton (1996), we believe that the key to successful succession planning lies in relationships. To emphasise the centrality of relationships for operating a family business and throughout succession planning processes is to make a simple, even anodyne point however, we suggest that this commonplace insight might actually offer family business researchers a useful alternative approach for understanding what happens during family business succession planning. Moreover, it holds potential for facilitating advances in our analysis of family firm conduct in general. Relationships are about connections, ties and the myriad webs and networks arising from them; in other words they go to the heart of the socially embedded nature of business behaviour and the context which surrounds family business.

Family business research needs a constructive method of approaching succession planning from the perspective of relationships which will open up new insights into the contextual and socially embedded nature of family businesses. The related concepts of 'social capital' and 'social network analysis' appear to be most suitable for this purpose. They represent a conceptual approach with enough flexibility to enable us to view succession planning through other 'lenses' that might clear away some of the impasses and allow us to further build our research on the substantial foundations already laid by others.

In the first section of this paper we briefly cover what can be found in the existing literature on succession planning and what this indicates about what we presently know and do not know. In the middle section we discuss the emergence of relationships as a primary perspective for understanding succession planning and argue for family business research to more fully use the conceptual approach offered by the notion of social capital. Finally, we provide a section outlining examples of research employing these approaches to stimulate some new thinking about our research agenda. Applying social capital's conceptual lenses to the problem of succession planning may assist us to prise open some of the 'layers of embeddedness' – of family context within business context within social context – which complicate our understanding of family businesses.

## **DISCOVERING WHAT WE KNOW AND DO NOT KNOW**

In this initial section we will outline the material gathered in our recent survey of the extant literature on succession planning in family business. Existing family business research contains information on many factors, processes and relationships that influence succession planning. Also to be found are attempts to devise a general model for engaging in family business succession planning. However, in line with other recent research, we would conclude that

significant gaps currently remain in our overall research agenda and knowledge regarding succession planning (Le Breton-Miller et al., 2004; Sharma, 2004). While this is not completely good news, we wish to emphasise just how much useful work has been done in building our current family business research canon. Our message here is less about ‘problems’ in our research than it is about the existing opportunities to augment, understand and interpret what we already know about succession planning.

Numerous influences on succession are identified in the literature and they can be categorised in numerous ways, and Venter, Boshoff and Maas’ (2003) distinction between ‘hard’ and ‘soft’ issues is one recent example. For the purposes of this section though, we only intend to sketch the outlines of the existing literature to illustrate our knowledge strengths and weaknesses. A more exhaustive discussion of these influences can be found in Le Breton-Miller et al. (2004) and Dunemann and Barrett (2004). Research has focussed upon the importance of good quality communication in succession planning (Hamilton, 2003; Janjuha-Jivraj and Woods, 2002a; Lansberg, 1999; Thomas, 2002) and on maintaining an environment conducive to good communication (Paisner, 1999). Psychological influences also feature, often with examples of research covering the effect of individual perceptions regarding roles, intentions and attitudes (Sharma, Chrisman and Chua, 2003), emotional and relationship obstacles (Kirschner and Kirschner, 2000), psychological conflict (Grote, 2003), and various incumbent personality types (Poza, 2004).

On offer are also many examples investigating the effects of the different stages of the life cycle in which individuals and firms may find themselves during succession (Janjuha-Jivraj and Woods, 2002b; Lansberg, 1999; Miller, Steier and Breton-Miller, 2003). Research on the preparedness levels of the principal individuals also appears frequently (Barach, Carson et al, 1988; Fritz, 1997; Morris, Williams, Allen and Avila, 1997; Sharma, Chua and Chrisman, 2000) as does that on the importance of having a preparation process for each person (Cadieux and Lorrain, 2003; Cohn, 1992; Levinson and Wofford, 2000) and the preparations of these individuals (Allred and Allred, 1997; Fiegener, Brown, Prince and File, 1996; Garcia-Alvarez and Sintas, 2003).

Material articulating the important influence exerted by goals and value systems (Chrisman, Chua and Litz, 2003; Chrisman, Chua and Zahra, 2003; Garcia-Alvarez and Sintas, 2003), as well as that of the business and family cultures (Belardinelli, 2002; Garcia-Alvarez, Lopez-Sintas and Gonzalvo, 2002; Gatrell, 2003; Goffee, 1996; Longenecker and Schoen, 1978) in planning for succession, also exists. Discussions about the crucial role of management systems in family business succession planning (Dyck, Mauws, Starke and Mischke, 2002; Hamilton, 2003; Lee, Lim and Lim, 2003; Morris et al., 1997; Taylor, Norris and Howard, 1998), and the influence of financial (Kimhi, 1997; Thomas, 2002) and business environment factors (Bjuggren and Sund, 2002; Burkart, Panunzi and Shleifer, 2003; Shen and Jr, 2003) can also be found.

Despite this array of material we argue that there are many things we do not know or at least do not understand or explain well enough. Others agree with us, for example, Sharma (2004) who suggests that we need to better comprehend how and why family firms so readily endure in diverse locations and to improve our understanding of their societal interactions. Sharma (2004) also calls for more efforts to explore interorganisational relationships and how firms develop

culture and vision. Zahra and Sharma (2004: 335) have also indicated that the family business research focus is too narrow and that this has resulted in a family business research base which is “fragmented and descriptive” (p. 344), leaving us with many gaps in our knowledge.

In terms of understanding succession, Le Breton Miller et al (2004) argue that little has been done to address the issue of context, which includes the family, social, industry, and business context. They argue that many succession studies include only a few variables, concentrate on easily investigated aspects of succession, and focus more on individuals than organisational dynamics. Furthermore they argue that it is more often the anecdotal material which is used to grapple with the “under-explored categories” (Le Breton Miller et al, 2004: 319) of succession planning, which are those involving context and interactive processes. Unfortunately, they point out that a less research time appears devoted to exploring these gap areas in recent years than was previously the case (Le Breton-Miller et al., 2004: 322).

Little is known about how complex factors in succession fit together and interact. For example not enough is known about the dynamics of nurturing and developing successors (Le Breton-Miller et al., 2004). What are the advantages of gaining experience internally versus externally? How do we create the appropriate cultures and value systems? How do these actually influence outcomes? As a result we cannot adequately explain or understand much of what happens around these issues which involve high degrees of social and personal dynamics. What we require are methods that can illuminate these matters and allow us to investigate more fully the “tacit and social knowledge” (Niemelä, 2004: 320) which are crucial to understanding family business behaviour. In the next section we will discuss how the allied notions of social capital and social network analysis offer us the potential to grapple with these most pressing family business matters.

## **NEW PATHWAYS**

Despite an array of factors and processes involved in succession planning there remains a pertinent sense of the centrality of relationships to succession planning. Following Fox et al. (1996), we suggest that the key to successful succession planning lies in relationships. Good succession planning outcomes are more likely when we more fully understand and are better able to manage family business relationships generally. As such, furthering our understanding of succession planning entails examining succession planning through a ‘relational prism’.

If we can better grasp what happens during succession processes from the perspective of relationships more generally, then our comprehension of so much that happens is likely to be enhanced. One reason for this is because the complex web of relationships which exist within family business is, in some senses, synonymous with the overall context, both social and business, that underpin the conduct of family business, a dimension which is presently little understood. Better understanding matters at this level could assist us in fitting what we already know into a broader framework of analysis. This requires us to employ and test different research tools and we consider ‘social capital’ and ‘social network analysis’ to be the best concepts available at present. Others have already begun applying these ideas to various problems in organisational research and they appear to offer the most potential for better understanding succession planning and family business practice more broadly. For example, Mustakallio, Autio

and Zahra (2002) have made some use already of this idea saying that “social capital theory appears to be highly applicable to the study of family firms” (Mustakallio et al, 2002: 219).

The notion of social capital and social network analysis stem from the work of a wide variety of researchers and is often linked with the early efforts of figures such as Granovetter (1973), Burt (1982), Bourdieu, Coleman, and Putnam (Schuller, Baron and Field, 2001). Social capital can be considered as a “set of resources rooted in relationships” with a central premise that “networks of relationships” are valuable in conducting social affairs (Nahapiet and Ghoshal, 1998: 243). In this sense “social capital is the contextual complement to human capital” Burt, 1997: 339), the content of what exists as a result of the positioning, interaction, and interplay between the various individual entities. Three facets of this have been identified as the structural, relational and cognitive aspects which respectively relate to: the overall position of actors within any network structure (location), the quality of connections and relations (eg. trust), and common frames of reference and action (having a shared paradigm) (Nahapiet and Ghoshal, 1998).

This ability to analyse various aspects of the behavioural influences emerging from the pattern of relations between individuals, as opposed to that due to individual factors, is a real strength of this approach (Schuller et al., 2001: 35). It allows us to view succession planning and family business behaviour from fresh perspectives that accommodate the “complex and multi-faceted nature of social reality” (Schuller et al., 2001: 23). This is particularly useful when analysing succession which often unleashes “complex relationship issues” (Zahra and Sharma, 2004: 334) latent within the firm. Social capital can be used to avoid both ‘over’ and ‘under’ socialised views of human action (Granovetter, 1985) which can blind us to the reality of family business behaviour. In viewing matters from several angles simultaneously (Schuller et al., 2001: 29) we may avoid the limitations of more linear approaches (Schuller et al., 2001: 30) and move beyond our continued reliance on the same well used methods of research and analysis which have left us struggling to advance our knowledge and understanding (Zahra and Sharma, 2004).

An example of the insights to be gained can be found in Coleman’s (1988) work on education where he links the levels of closure or openness in a particular network of relations with the capacity to reinforce values and cultures. This is one example of the way in which social capital can be used as a conceptual tool to reinsert value into family business research and to explore the affects of relationship quality (Schuller et al., 2001: 36). Also noteworthy is the ability to use social capital to link various levels of analysis and to handle ambiguity such as is found in relationships experiencing both conflict and cooperation (Schuller et al., 2001: 35). Probably most important of all, however, is the “heuristic quality” (Schuller et al., 2001: 36) of social capital which promises to open up fresh and unexpected paths in our research of family business.

## **USING SOCIAL CAPITAL: SOME EXAMPLES**

This final section of our paper will be used to provide some examples of research undertaken using social capital and network analysis as conceptual approaches. The first example is Steier’s (2001) work where he directly applies these ideas to a particular issue in family business succession planning. Further examples are used to show the way these notions have been utilised in other areas to open up new perspectives on matters of interest to that research discipline. These are offered as a way of assisting researchers in family business studies to begin

considering whether and how the concept of social capital might be applied to improve our grasp of various aspects of succession planning and business conduct in general.

Steier (2001) adopts the importance of relationships and the notion of social capital as a starting point in his study of the way social capital is managed within family businesses. To begin he emphasises the distinction between physical capital (i.e. equipment, land or cash), human capital (such as individual's knowledge, capabilities or physical appearance) and social capital (the assets embedded in various relationships) (Steier, 2001: 259). Each of these, variously, contributes elements of value that together comprise the accumulated assets contained within a firm. This is important as most succession research only focuses upon wealth transfer and asset management in family businesses as it relates to physical and human capital. This study seeks to understand the third dimension of wealth transfer and its impact upon succession in family firms (Steier, 2001: 260). Through a series of interviews with family business successors, Steier (2001) identifies four different modes of social capital transfer within family firms: a) that which occurs when a succession is sudden and unplanned, often the result of an unexpected death; b) that which is rushed, perhaps due to a family illness or divorce; c) a natural immersion over a long period; and d) where a conscious effort to transfer these assets is undertaken (Steier, 2001: 265-7). He also uncovers seven means by which families manage social capital within the business. These are 1) "deciphering existing network structures"; 2) "deciphering the transactional content of network relationships"; 3) "determining criticalities"; 4) "attaining legitimacy"; 5) "clarifying optimal role"; 6) "managing ties through delegation and division of labour"; and 7) "striving for optimal network configuration" (Steier, 2001: 265). Through exploring the accumulation and movement of social capital within family firms this work illustrates the "importance of relational assets" (Steier, 2001: 275) in family business and concludes by suggesting further questions to be investigated.

In a recent paper, Nicholson, Alexander and Kiel (2004) employ the notion of social capital to explore how the operation of company boards affects overall corporate performance. Working with a 'resource dependence theory of corporate governance', which examines the role played by a board in providing a company access to resources, they attempt to distinguish between the effects of the corporate network and the networks that exist at the level of personal directors on a company's access to resources (Nicholson et al., 2004: 54) They examine the impact on corporate performance of individual linkages as opposed to linkages at the level of the firm (Nicholson et al., 2004: 57). The multidimensionality of social capital is acknowledged as a conceptual approach and they focus their efforts upon the 'structural' dimension of social capital – the links or bonds between actors. They use publicly available data to determine what linkages exist at the personal level between company directors and the proximity of those connections in both Australia and the USA (Nicholson et al., 2004: 61). They found interconnections at the corporate level were similar in the two countries, however, significant differences emerged at the personal level with interactions between directors in the USA much higher than those in Australia (Nicholson et al., 2004: 64). As a result they suggest that if a large part of a board's social capital and access to resources comes through personal, rather than firm level connections, then these differences could have implications for understanding any comparative studies on corporate performance. Particular questions of interest that arise include 'Given the greater personal integration of company directors in the USA, could we expect to see faster and better diffusion of innovations?', 'Does more social pressure also accentuate negative effects such as

malfeasance?’ and ‘Do minority directors in the United States wield more influence?’. As a consequence, Nicholson et al (2004: 65) call for further research in these areas.

A further insightful example of the use of social capital as a research approach is found in the work of Fernandez, Castilla and Moore (2000) who use it to better understand the process of employing new staff through referrals by existing workers. They argue that also this matter has been previously explored using social capital this has focused on supply-side issues only (Fernandez et al., 2000: 1288), and their research addresses this matter from the demand side – the employer’s perspective. Fernandez et al (2000) examine the hiring records of a large telephone company and show that a ‘return’ (in better hiring outcomes) of \$416 for every \$250 of ‘social capital’ investment (in the form of paying existing employees a referral bonus to recruit staff) is realised. They therefore ‘prove’ social capital as a concrete form of capital and provide good reasons for understanding why firms might hire in this way (Fernandez et al., 2000: 1351). They also suggested that a social capital perspective offered support for two prevailing economic theories – ‘the richer pool process’ and ‘the social enrichment process’ – but little to support the ‘post hire better match story’ (Fernandez et al., 2000: 1351). While admitting that more work is needed, they emphasise in their conclusion how this social capital approach can provide empirical evidence for certain hypotheses. Fernandez et al (2000) encourage others to conduct empirically grounded case studies as a way of augmenting our theoretical knowledge (Fernandez et al., 2000: 1352-3).

Other examples where the notion of social capital is used to further explore research questions are found in three further papers. The first is by Pennings, Lee and van Witteloostuijn (1998) who examine historical data in Holland to determine if levels of social capital and human capital can be implicated in firm dissolution. They look at variables such as the number of firm partners who had experience working in different industries and, particularly, in industries like those of their client base in order to ascertain levels of social capital (Pennings et al., 1998: 430). They found that levels of social capital strongly predicted firm survival, with higher levels of social capital associated with firm persistence (Pennings et al., 1998: 437). This study only focuses on a particular industry and the authors caution that more research should be undertaken (Pennings et al., 1998: 439).

Brass, Butterfield and Skaggs (1998) also employ a network analysis to investigate unethical behaviour in organisations. This paper examines the role relationships might play in determining the formation of shared norms and values in organisations. Brass et al (1998) suggest that the network of relations can both constrain and enable opportunities for unethical behaviour. They argue that by focussing on the relations between actors in an organisation then ways of understanding where problems might arise can be provided which can be helpful in devising methods to mitigate the emergence of unwanted behaviour (Brass et al., 1998: 25-26).

The third of these papers is by BarNir and Smith (2002). They examine the links between a propensity for networking and the creation of interfirm alliances in small businesses. Using propensity to network, the strength of ties, and network members’ prestige as factors BarNir and Smith (2002) survey small businesses and correlate the results with the number of alliances made by a firm (BarNir and Smith, 2002: 228). For these small businesses they find that the number of interfirm alliances is positively associated with higher degrees of social networking, when

considered from the perspective of the quality of those linkages. Where firms have low quality but a larger scope of linkages, the association is negative (BarNir and Smith, 2002: 229).

In providing a brief overview of some already existing research using social capital as an analytical tool we have demonstrated how the work of others might give glimpses of new research openings for research into succession planning in family business. By linking our research with the efforts of others we may all benefit from expanding the scope of our research agenda and sharing common research problems. New lines of inquiry could be made in tandem with other disciplines which may prove fruitful for all concerned. This could help address a concern raised by Bagby (2004) that interaction between disciplines on common concerns such as succession planning is too limited. As well, we may discover information that applies to family business research more broadly and perhaps, even to research outside our discipline. This would go some way to allaying the concerns of Zahra and Sharma (2004) in their recent reflections on the state of family business research. Our adoption of a bold new research agenda may be part of wider efforts needed to raise the profile of family business studies and to more fully communicate with sister disciplines.

## CONCLUSION

Initially, our purpose was simply to review the family business succession planning literature in order to service the needs of Australian family businesses which are increasingly concerned with how to actually go about making plans for succession. What emerged was recognition of some critical gaps in our research knowledge and of the opportunities that now exist to augment and systematically build upon the excellent work already done. As a consequence of these efforts we realised, as well, how much of the extant literature pointed to the centrality of relationships in succession planning, a point clearly noted by Fox et al. (1996). Good succession planning lies in managing relationships and we recommend more efforts to understand the nature and influence of relationships in succession planning. Most promising for this purpose are the conceptual tools offered by social capital and social network analysis. They enable us to explore the substantive nature of the ties and interconnections that operate within family businesses as well as ways in which relational dynamics influence succession and family firm performance in general. Early examples of the application of these concepts to business and organisational research indicate the potential and we encourage family business researchers to more thoroughly explore its potential. Social capital and social network theory have to expand our understanding of family business succession and behaviour in family business more generally.

## **ABSTRACT**

The purpose of this paper is to explore the nature and type of financial records being kept in small businesses in Australia. The paper considers the Australian requirements for financial record keeping and the context in which small businesses are required to record and report. The research literature on the benefits of record keeping and the use of the financial information that they can generate for small businesses is considered. The findings from 121 responses to 1000 mailed survey questionnaires are considered and a discussion of these results includes comparison of the findings in the literature. The financial data used by these small businesses in their business performance evaluation is compared to what is known in the literature. These results have highlighted areas for further research via case study analysis.

## **INTRODUCTION**

Small businesses are important in the global economy, despite variations in how they are defined. In the UK for example small firms (businesses with less than 250 employees) represent over 90% of the business population and provide nearly two-thirds of the national employment (Mitchell and Reid, 2000). In Norway small businesses (1-19 employees) represent “(a)bout 95% of Norwegian firms” (Gooderham et al 2004, p. 6). America defines small business as businesses employing fewer than 500 employees (Holmes 2001) and it is estimated that in 2002 there were 22.9 million small businesses, employing 50.1% of the private work force and represent 99.7% of all employers (United States Small Business Administration 2005).

The Australian Bureau of Statistics (ABS 2002) estimated that in Australia during 2000-01 there were 1.2 million small businesses (employing less than 20 employees), with a total employment of almost 3.6 million people. This represents 97% of all private sector businesses in Australia. Small businesses dominate all industrial sectors although numbers are greater in the services sector in comparison to the manufacturing sector.

The small business sector makes a significant contribution to the Australian economy by providing employment, personal wealth, supply of goods and services and utilization of resources. However, while entry into small business is a simple process requiring an investment of individuals' resources, time and skills, as there are no minimum standards or qualifications required to be met prior to business entry, remaining in business can be difficult and requires meeting ones debts as required and complying with legislation relevant to business operations. The business owner's skills and knowledge may not extend beyond those relevant to their

industry. Financial skills may be very limited and hence, understanding financial requirements and how they can use financial information for performance purposes may also be very limited (Thomas and Evanson 1987; Holmes and Nicholls 1988). This can be problematic as “the compliance costs of taxation comprise the largest single element of the compliance burden by businesses” and government regulations have been “claimed to be one of the major obstacles to business success” (Chittenden et al. 2003, p. 94).

The purpose of this paper is to ascertain what record keeping and financial reporting small business owners use in their business. This is an important issue in the context of GST and annual taxation reporting as well as the introduction of International Accounting Standards. In order to better understand the role of financial record keeping and reporting this paper will explore the benefits found from record keeping and financial reporting, the impact or effect of the GST on the nature and type of record keeping, information available from record keeping, and the use of that information and what understanding can be gained from the use of such information. A study of small business in one Australian region was conducted to explore some of these issues and is reported in this paper. The type and size of small business revenues and expenses can vary significantly: from many transactions of small to medium dollar amounts to fewer transactions of greater dollar amounts. It is therefore important to consider if the record keeping, reporting and information used within businesses differ. The current recording and reporting requirements and their subsequent role in small business will be examined in detail in order to determine the use of financial information and possible improvements within current reporting requirements.

In the following sections the paper details the introduction of the Australian GST, benefits of record keeping and financial reporting to contextualize the research. In these sections the literature on small business financial recording and reporting together with the importance of financial management skills to small business success are considered.

## **THE GST, COMPLIANCE AND RECORD KEEPING IN SMALL BUSINESS IN AUSTRALIA**

### **The GST: Its Introduction and Effect**

On July 1, 2000 the Australian Commonwealth Government introduced a Goods and Services Tax (GST) of 10%. While the GST replaced a range of other Australian taxes, its introduction was met with much resistance from the business community generally. GST compliance requires accurate recording and reporting records regardless of the level of financial skills of small business owners and managers. The GST has increased the level of reporting of transactions and the frequency of reporting even though previous legislation did require all businesses to keep records which “record and explain” (ATO 2002) all business transactions.

The GST has made business an integral part of the taxation collection system and small business self assess their taxation obligation. The self assessment is dependent on the record keeping and financial information. The reporting timeframe to the Australian Taxation Office (ATO) has increased from annual taxation returns to monthly or quarterly taxation Business Activity Statements (BAS) in addition to the annual taxation returns. The timing of the BAS is dependent on how the small business registered for the GST. The BAS details the business receipts and payments together with the GST received and paid for the period.

This increased reporting has focused attention on the need for accurate recording and reporting of business operations in financial records. To overcome this, in the period prior to the introduction of the GST, the ATO and the accounting profession provided business advice to assist small business in understanding their role in the GST and the new recording and reporting requirements.

While the ability of small business to comply with the GST system is currently being researched together with burden of compliance, the question of whether the type of records are kept rather than simply issues of compliance has not yet been addressed. This is important as Melbourne newspapers have reported that the ATO is implementing additional investigations and audits to curb and reduce the perceived tax avoidance and continuing cash economy (Crawford 27 June 2003).

Further studies on the impact of the GST, for example that by CPA Australia, found there is “an incentive to keep up-to-date with record keeping” and produce reports regularly (CPA 2003, p. 6). However, this study did not address the nature or type of record keeping and/or reporting used by small business owners. CPA Australia reported that the ATO has identified poor record keeping as one of the major causes of tax compliance problems for small business. This has recently been reinforced in media articles from the ATO (Lawson 8 February 2005). CPA Australia also found that the role and volume of assistance provided by the accountancy profession had increased; with 50% of CPA Australia members experiencing service increases and 41% of small businesses experiencing an increase in their accounting costs as a result of compliance. These costs extended from recording of transactions to the preparation of compliance reports.

Petzke and Murphy (2001) examining the impact of the GST on small business, and hence argued that the goods and services tax was perceived by small business owners to be extremely costly for them in the first year following its introduction, both financially and in terms of the demand on the owners' time. This research found little evidence of the benefits that the Government claimed would accrue to small business with the introduction of the New Tax System (p. 20). Since the introduction of the GST the Australian government has tried to simplify the reporting in response to business backlash. This continues to be discussed and debated in business and government circles. Whilst it is encouraging that the GST has increased the timeliness of record keeping and reporting to the ATO, the use of financial information by small business needs further considerations.

### **Financial Management and Reporting: Benefits and Issues**

A range of research has found poor accounting systems strongly contribute to financial problems in small business by (for example McMahon 2001a; 2001b; McMahon and Davies 1994; McMahon and Holmes, 1991) and others. For example in his research into the different life cycles of small business, McMahon (2001a) found that of all financial problems encountered by small business, poor accounting systems account for 32% and poor cash flow 26%

Other research has linked improvements in business performance through use of financial information. McMahon and Holmes (1991) write that “the clearest and most startling distinctions

between successful and discontinued small businesses lie in their approach to the uses which can be made of accounting information” (p. 19). They go on to argue that “sound financial management is crucial to the survival and well-being of small enterprises of all types. Studies of reasons for small business failure inevitably show poor or careless financial management to be the most important cause (p. 19).

While there is clearly a relationship between business failure and financial management which relies on accounting information, the questions must be asked as to ‘what accounting and financial information is recorded and maintained in small business’ and ‘how is it managed?’. Also the question as to ‘what information do small business owners use to run and grow their business?

Answering such questions are important given the Australian Taxation Office state that micro-businesses (turnover less than A\$2 million) represents 12% of tax revenue but accounts for 68% of debts owed to the ATO, forming the highest compliance risk area. They stated that these businesses “struggle to keep up to date with their record keeping and will have difficulty with changes to the revenue system” (Lawson 8 February 2005). The variation in definitions re small and micro businesses blurs this picture, however the micro or smaller small businesses fall well within this group of concerning ATO clients.

To decrease the burden on small business perhaps compliance reports could be modified to be beneficial to small business owners in running their business? Or could it be that more timely financial information is sufficient benefit? Compliance taxation or modified reports may assist business in their monitoring of business performance if these reports contain the information small business use to monitor performance.

How small business can best use financial information to evaluate business performance is not addressed well in the literature. Although the GST has increased the volume of work for Accountants and small business themselves, CPA Australia argues that “few small businesses would dispute the need for regulation; the majority find its impact on their ability to operate to be quite substantial” (CPA 2003, p. 4). They go on to say “three quarters of small businesses claim that compliance obligations act as an incentive to keep up-to-date with record keeping and that they run financial reports regularly to manage the business” (CPA 2003, p. 6). However the questionnaire that was used to provide this finding did not identify what financial reports were produced and how were they used to manage the business: In other words the information that small business owners actually use to monitor performance has not been identified in detail. The next sections consider some ways in which records can be kept and the types of information contained within them.

## **Record Keeping**

McMahon (1999; 2001a; 2001b; 2003) considered financial reporting and its benefits for small business, particularly general purpose reports (Profit and Loss, Balance Sheet and Cash Flow statements) and the use of some figures from these reports for performance measurements. The research did not detail which of the figures or how the performance measurements from these reports were performed. In a study of manufacturing small businesses in Australia it was found that financial planning and control processes had a significant correlation with higher growth in

sales (Wijewardena and Zoysa, 2001). However these studies were based on small business in the manufacturing industry, which is only one of the many industries in which small business operate. In fact this industry represents only 7% (or 88,200 businesses) of small businesses in Australia in 2000-01 (ABS 2002), and hence the nature and type of financial management issues in this industry may be industry specific and may not be applicable to all small business operations.

Argilés and Slof (2003) found that financial reports were useful in the agricultural sector to improve performance, but only where the costs of obtaining the reports was less than the expected gain in performance from the use of these reports. In the case of the smaller farms, the cost was found to not always being worthwhile (Argilés and Slof, 2003). This research did not discuss how the farmers used the financial reports or what figures were important to the business owners to assist in the understanding of “*how* accounting information enhances performance” (p. 263). Other research by Kirby and King (1997) considered the role of the accountant assisting small business and identified the mismatch of expectations between the business owner’s and the accountant’s view of their roles.

In the literature review conducted by McMahon and Holmes (1991) of the North American small business financial management practice they discuss DeThomas and Fredenberger’s (1985) survey of 360 small businesses in Georgia, USA. This research found that 81% of those small businesses produced summary financial reports and of those, 91% produced general purpose reports. This review also discussed Thomas and Evanson’s (1987) study of 398 small pharmacies in the US. Thomas and Evanson found that 62.5% produced quarterly (at least) profit and loss and balance sheet statements. Of note over 85% from this sample outsourced the statement preparation to accountants. The ratio calculations and preparation of balance sheets were considered in relation to business performance and indicators of business performance. The findings at times were contrary to what was expected such as “less frequent preparation of balance sheets was associated with greater earnings” (p. 567). In their limitations they noted it is one thing to produce the information, another to use it, and if these statements are to be useful they must be understood by small business owners/managers (p. 569). The authors argue that the business owners “lack of association between financial ratio use and either survival or profitability may also indicated the level of sophistication in use of ratios has not reached” sufficient levels in business owners to make “discernible difference” (p. 570). DeThomas and Fredenburger (1985) found only 11% used financial statement information in their managerial evaluation even though 61% felt the information could be used for planning and decision making. Also they found 2% performed financial ratio analysis and performed historical comparisons of performance and position. This is a harsh finding for the 81% producing summary financial reports that only 11% use the financial statement information in their managerial evaluation. However it is consistent with the findings of Thomas and Evanson. Often short term planning is performed informally even “in the back of their minds” or “on the back of envelopes” (McMahon and Holmes, 1991 p. 22).

However given American small businesses are much larger than Australian small businesses transferring findings from one country to another may be problematic therefore it is important to gain a greater understanding of what small business are doing in relation to record keeping, how they are doing it and why they are doing it, in order to be able to better meet their needs and assist the longer term survival of the sector.

## **Compliance Requirements**

Taxation law require all businesses to keep records which “record and explain” all business transactions (ATO 2002, p. 33). The ATO recently advised that small businesses will be fined for poor record keeping (Lawson 8 February 2005), however did not define poor records. Accounting records could be as basic as a collection of receipts and cheque butts (often referred to as ‘shoe box’ accounting) or as sophisticated as a computerized accounting package (packages such as Mind Your Own Business [MYOB] or Quick Books) which are capable of detailing every transaction including all amounts owed to and owing by the business. The size and type of the business will impact on the level of record keeping most appropriate to that business, together with the importance placed on the recording by the business owner. Fewer transactions would allow for less sophistication in the recording system whilst larger volumes would require more.

Accounting professionals assist small business with their record keeping and compliance reporting and some small businesses may involve the accountant to prepare or review compliance reports produced by small business. These issues further vary the level of record keeping. Hence research must be able to differentiate findings involving record keeping and reports produced by accounting professionals to those maintained and produced solely within the small business. In quantitative research this can be done by incorporating a section on “accounting professional involvement” as a means of providing a control sample of the sound record keeping and compliance reporting.

## **Information Record Keeping can Provide**

Whilst a collection of receipts and cheque butts allows for the production of compliance reports, it is most difficult to produce performance reports without summarization. Computerized systems on the other hand allow for reports to be produced ‘at the push of a button’ but their value is dependent on both having accurate information entered into the program and owner/management having the skills to read and interpret the information produced.

Accounting education, accounting profession and literature at length, focus on the production of business performance reports and their benefits to business. This focus includes the production of performance evaluation reports including profit and loss determinations (Profit and Loss Statement - Statement of Financial Performance), statements of business worth (Balance Sheet - Statement of Financial Position) and statement of Cash Flows. Currently Australian legislation (Corporations Act) requirements for small business require only incorporated small businesses, that is, companies, to produce business performance reports. Given that is estimated that some 50 percent of small business are incorporated (Senate EWREC 2003), the remainder are sole traders, partnerships, and trusts who are not required by legislation to produce performance reports.<sup>1</sup> Therefore the ATO compliance reporting (BAS and Annual Income Tax returns) are at present the only required record of business reporting for all small business. These compliance reports are not business performance reports rather a report that allows the ATO to calculate business tax (payable or refundable) and statistical data. The ATO uses this data to identify business averages as well as to select businesses for taxation audits.<sup>2</sup>

Business reporting is an important issue to consider at present as Australian reporting entities move to the adoption of International Accounting Standards (IFRS) from January 2005, changing the financial reporting currently in place. As the business environment and media are currently focusing on financial reporting, consideration of small business financial reporting should also be made. For most Australian small businesses there are no specific accounting standards and legislation as noted above does not require small business to produce performance reports, which McMahon and others found to be important. At present only reporting entities and private companies defined as large by the Corporations Act are required to comply with Accounting Standards according to Chief Accountant of the Australian Securities and Investments Commission (ASIC) (Andrews 17 Feb 2005). All companies within Australia are required to lodge with ASIC annual financial statements however these maybe simple financial statements as only the defined large companies are required to comply with accounting standards. Where accounting professionals are used for the production of these financial statements (both small and large companies), the compliance with Accounting Standards may be performed even though the business may not be considered by ASIC and hence does not have to comply with IFRS. At present there is confusion and disputes in opinions as to the impact of the introduction of IFRS. Britain and other European Union countries are also introducing IFRS, however Australia is the only country in which the standards being introduced may apply to unlisted companies (Andrews 2005).

Despite the requirement to produce GST compliance reports and the research findings on the importance of financial management skills, it is unclear whether and how (if at all) Australian small businesses use the information contained within compliance reports to help them manage their business. There is a need to consider in more detail the role of compliance reports and the possible link of compliance reports to performance reporting. Research needs to examine both the practice and attitudes: where practice refers to how information is recorded, what information or complexity of information is recorded, financial management skills (or use of accounting professionals) to produce reports and utilise financial information, and attitudes refers to the owner's motivation for business as well as the importance they ascribe to financial information in determining business success. Research has focused on accounting professionals as advisors and service providers to small business, but there is a need to identify what small business want and understand from accounting information. The question of whether small business people view the importance of utilising performance reporting needs to be asked. Answering these questions will enable the attitude to information and operational use of reports to be better understood and will provide important insights for both academics and practitioners. These are important issues to consider from both an academic and practitioner perspective as financial management skills or lack there-of play a significant role in the small business failure rates.

The key question being addressed by the study in this paper is to identify how small businesses are recording financial transactions and what financial summaries and reports are produced from this information. The small business characteristics are considered in the nature and type of recording and reporting being performed is identify if these factors impact on the recording and reporting. The research methodology and approach to a study of small business financial information reporting and use is in the following section.

## **RESEARCH PROGRAM AND METHODOLOGY**

Twenty-four per cent of the 1.23 million private sector small businesses (or of the 97% of the Australian business population) are located in the state of Victoria, which is the second highest state based population of small business in Australia (ABS 2002). A random sample of 1000 small businesses were selected from the regional towns in Gippsland in South East Victoria via the public business phone records dated 2003 (Telstra White Pages 2003). Businesses were selected from each major town in this area so that each town was represented in the sample. However due to the dynamic nature of the small business sector, these records may not be an accurate listing of all businesses operating at any point in time.

A questionnaire was developed in three sections.

- Section One - Size and Nature of small business asked questions to identify business demographic data including number of owners, length of ownership, age of business, number of employees, annual business turnover, industrial sector and business structure.
- Section Two - Nature and type of financial records and reports in small business addressed questions including business receipt and payment methods, record keeping methods source of the production of taxation reports, summarization of financial information its timeliness. The existence and use of business plans were also included.
- Section Three - Use of financial information in business addressed the issues of business performance evaluation and usefulness of financial statements and other reports if produced.

The questionnaire was piloted prior to its finalization by sending it to business owners to complete or by the researcher sitting down with the business owner as they completed the questionnaire. This enabled the researcher to consider any language or interpretation issues and address these as they were raised. The final questionnaire was mailed to 1000 businesses with an explanatory letter and a follow-up letter was forwarded to all non responding businesses two weeks later.

From the 1000 sample, 103 questionnaires were returned to sender, and 156 replies were received. This reflected a response rate of 17.4%. Of the 156 replies, 121 small business responses were useable and have been considered in the subsequent analysis and discussions. Only businesses employing less than 20 employees were selected for continuation in the study. The low response rate may reflect the perceived sensitivity of the questions. While no financial figures were requested in the questionnaire, some unusable returns did indicate that the questions were perceived as being intrusive.

## **RESULTS**

Of the 121 businesses, 31% were aged 10 to 20 years, 41% were aged 20 years or older. A significant proportion of responding businesses were long established businesses: only 18% were aged between five to 10 years and 7% were less than five years old. Some 33% of the businesses had been run by the current owner for 10 to 20 years (33%) and another 29% had been operated by the current owner for 20 years or more. Again this indicates that the businesses were well established with only 21% of respondents operating their business for 5 to 10 years and 14% operating their business for less than five years.

Most responding businesses (69%) employed between 0-4 Equivalent Full Time employment (EFT), and therefore these businesses are also micro businesses. The business turnover was found to be well spread between various ranges: 13% had a turnover of less than A\$50,000 11% had a turnover of between A\$50,000 to A\$99,999, 16% were in the A\$100,000 to A\$199,999 range, 25% were in the A\$200,000 to A\$499,999 range, 19% in the A\$500,000 to less than A\$1 million and 10% had a turnover of A\$1 million or more. In 84% of cases this business was the business owner's main source of income. In 97% of cases the business records were maintained within the business.

In Table 1 it is possible to see that the receipt of monies and payment of monies varied with most small business owners accepting multiple receipt methods and making payments by multiple methods. The use of electronic means for both receipts and payments was found to be well used in these long established businesses.

---

Insert Table 1 about here

---

Table 2 details the many records used to record receipts and payments. In Table 2 we see that accounting software is used more for the recording of receipts than for payments. Eighty-six businesses or 71% of respondents advised the use of accounting software for receipts whilst only 77 or 64% used software for payments.

---

Insert Table 2 about here

---

Table 3 details the production of the taxation compliance reports. Fifty-eight percent of small businesses produce their own BAS and 11% produced their annual taxation return. Thirty-one percent of business owners used their accountants to produce their business BAS and 87% to produce the business annual taxation return.

---

Insert Table 3 about here

---

Table 4 shows the type of business financial summarization performed in the businesses. The summarization of revenues is performed more extensively than the summarization of any one cost category. The summarization of revenues is also performed more extensively than net profit summarization.

---

Insert Table 4 about here

---

Table 5 details the production of financial statements in small business. The profit and loss statement is more likely to be produced than balance sheets or cash flow statements.

---

Insert Table 5 about here

---

Of the 121 businesses, 83% of business owners advised they did not have a business plan and only 17% of businesses said that they did have a business plan.

Business owners were asked to rate the usefulness or otherwise of the various statements and reports for their business. Table 6 shows their responses. The profit and loss report was rated by businesses to be the most useful report. The balance sheet and cash flow were noted to be useful to varying degrees. BAS was found to be the least useful statement. Not many businesses owners said they produced other business reports to assist in their performance evaluation.

---

Insert Table 6 about here

---

How the business owners knew their business was performing is provided in Table 7. The most frequent response was 'by knowing money in the bank' with 54 responses and 'performance evaluation using financial statements and financial information' ranking second with 35 positive responses.

## **DISCUSSION**

These findings assist in explaining what small businesses are doing with respect to financial recording and reporting. The use of accounting software was noted to be high, which is consistent with research on impacts from the introduction of the GST (Breen et al. 2004). It would appear from these findings that business owners do not utilize the cost or expenses information to the extent that they utilize revenue information. The lower use of accounting software and less summarization of cost categories could imply less focus on business expenses. This requires further investigation.

The usefulness of financial statements responses requires further comment. The sum of the useful and very useful responses for profit and loss reports was 87% (or 105 businesses), however only 69% (or 84 businesses) said they had this statement. Similarly with the balance sheet the favorable responses totaled 68%, (83 businesses) yet only 53% (or 64 businesses) had these reports. The most noticeable difference was in cash flow opinions where 70% (84 businesses) reflected favorable views yet only 36% (43 businesses) had this report. Thus while business owners had a favorable view of these reports, they do not necessarily have or use these reports.

The introduction of the GST in Australia, whilst increasing record keeping and reporting, could be argued to be of some assistance for small businesses. From the responses it is clear that small business owners are more likely to produce the BAS report than use an accountant. This would suggest that business owners are looking at their own financial reports and information each reporting period. These periods are more often than the annual taxation report and so could give regular and timely information to the business owners about performance.

The high percentage of businesses with financial statements, found by this study, compares favorably with the results from DeThomas and Fredenberger (1985) and Thomas and Evanson

(1987) studies. However in this study summaries were found to be mainly produced by the business and the reports are reviewed by the business owner. Whilst in some businesses the production of reports is outsourced, only 12 businesses or 10% advised that they outsourced the summarization function. Eighty-seven respondents (72%) advised that the owner reviews the summaries.

Argilés and Slof (2003) found financial reports to be worthwhile if the costs were less than the benefits. It could be argued that for Australian small business that the benefits are possible as the costs to generate financial reports from the records being maintained would not be large. The use of accounting software already in existence in small business allows for the generation of financial statements without further costs (apart from a push of the button and a few pages of paper)!! For those businesses with manual recording, much summarization is taking place and the formalizing of these summaries to financial statements would not be too onerous.

With accountants being the largest source for annual taxation returns, the production of financial statements by these professionals from the business records should be possible for minimum costs. These professions are in a very sound position to assist small business in the review and evaluation of financial statements to gain the insight of business performance from the statements.

In a further examination of the responses from businesses with business plans it was found that a higher majority of these businesses stated they knew how their business was performing through performance evaluation than those without business plans. These businesses (with a plan), on the face of the questionnaire responses, also had higher levels of financial summarization and made greater use of financial statements.

Limitations were experienced in this study through the self completing of the questionnaires by businesses. Also business owners who are weaker in the areas of record keeping and their use may not have completed the questionnaire therefore the findings may be biased as a consequence. Due to the number of responses received from the sample population it is not possible to make generalizations about small business recording and reporting. Whilst all industrial sectors and business types and variations in business ownerships were represented in the responses, the number of replies was not large enough to be statistically representative of any one group or of small business in general.

The benefit of this program of research is to gain a greater understanding of the role of recording and reporting in terms of the following issues:

- How might accounting standards, which are currently not specific to small business be improved?
- What is the potential for accounting practitioners to increase the usefulness of accounting information?
- How may ATO reports be adapted to increase their likelihood to contain information within them to be useful for performance management?
- What is the potential for including key data information fields as identified by small business in ATO reports?

- How may advice currently given by the various government agencies and consulting entities to new and existing small business on the usefulness and role of accounting information be improved?

## CONCLUSION

The purpose of this paper was to outline a research program to explore the nature and type of financial information used by small business to produce accurate taxation returns and whether small businesses use this financial information for other purposes. Financial information has been considered for its two key elements: record keeping and reporting. Record keeping refers to what records are maintained and what they record. Reporting of these records was also considered in the context of the introduction and operation of the GST regime.

The research program focused on reporting, as required by legislation, to identify the minimum standards that should exist in all small businesses. It was found that 97% businesses maintain their business records and it is from these records that financial information is gathered. The role of general purpose financial reports and compliance reports was considered in terms of their benefits and use within small business. Whilst businesses advised that they produce financial statements to varying degrees, the usefulness of the reports was much higher rated than the actual existence of the statements. To better understand why this is the case and how the statements are used in business performance evaluation and performance management further research is required. The research will also consider the assistance provided by accounting professionals in the recording and reporting process. Benefits of the small businesses' involvement in the taxation system have been considered and whilst record keeping is a compliance issue, it has enabled small business to have financial information sufficient for business evaluation. This positive aspect should be expanded upon to assist in educating small business of the value and role of financial information in the evaluation and how they may use this information to improve and monitor operations.

## ENDNOTES

1. Where accounting professionals are involved in the production of compliance taxation reports would usually be a matter of course to produce Profit and Loss reports and Balance Sheets for all business clients. These reports are available for performance evaluation and monitoring of performance, but the question remains unanswered as to whether they are used by small business.
2. Deductions or income allowable for taxation purposes vary from usual accounting treatment in many areas. Depreciation charges is a good example where amounts claimed for taxation does not reflect the business use or consumption of the business asset. Cash accounting may be applied for taxation purposes whilst accrual accounting may more appropriately reflect business operations. That is all cash received and paid may be advised to the taxation office rather than the business transactions that occurred in the financial year. Thus ATO compliance reports vary from performance evaluation reports and may be of limited benefit to small business for performance management.

### **ABSTRACT**

Current research examining economic development in distressed areas has frequently adopted Porter's 1995 Model of Competitive Advantage. According to this approach, a business located in the inner city could accrue such advantages as: critical location, local market demand, potential for integration with regional clusters, and availability of human resources. In addition, stakeholders may view the firm's investment as a socially responsible act resulting in an enhanced image. However, businesses in distressed, urban neighborhoods have their own special set of needs. Examples include: lack of economic engines, limited access to marketing and capital, safety and security, education, and viable leadership. Subsequently, long-term resident firms may cease to create jobs; their revenue may decline; and overall revenue that might have flowed into the neighborhood, either through jobs for area residents or purchased goods and services, may decline. This paper describes the results of a recent study performed in a distressed neighborhood in the Inland Northwest. The results are typical of other such neighborhoods across the United States. Some activities are suggested for amelioration.

## **INTRODUCTION**

Economic development is a priority and challenge for most communities and their stakeholders. Local governmental bodies are interested in providing jobs to their citizens, improving their tax base, and ideally, developing a contagion effect whereby new businesses are attracted to the area. Whereas the emphasis is directed toward distressed, urban neighborhoods, there are additional, potential benefits such as decreasing the need for public assistance among local residents and improving the quality of the workforce through increased job opportunities.

There appears to be greater urgency to develop low-income, urban neighborhoods as a means to address social issues such as crime, poverty, and government dependency as an alternative to government controls. Greater impetus was added when the federal government adopted stricter regulations dealing with the receipt of public assistance benefits (Sherraden et al., 2004).

Across the U.S. a positive response toward an improved economic environment has come from the neighborhood residents themselves. In reaction to disappointing experiences in the workplace, such as layoffs or inadequate pay, some individuals have taken the initiative to create their own opportunities through entrepreneurship. In sufficient numbers, this approach may be a significant part of an overall strategy to improve many distressed areas.

## **BACKGROUND**

The nature of this research is quite varied, reflecting different research questions from

various stakeholders; different forms of economic development and assisting agencies; and different definitions of success. For years, governmental bodies have been a primary stakeholder involved in economic development as a matter of policy. Attempts to influence the actions of business typically have come in the form of tax breaks for relocating its business units or for hiring “hard to employ” individuals; reducing restrictive regulations; and consideration in improving an area’s infrastructure. Over the years, the government has also supported social programs which have attempted to train individuals with few or no job skills as a means to reduce their dependency on public assistance and to improve the skill level of the local labor market. Many of these actions have been controversial, and their value questioned both by the public and government representatives.

### **Economic Development Modeling**

Porter (1995) offered an economic model as an alternative to the social investment approach whereby the private sector assumed the leadership role rather than the government. His premise was that the competitive advantage of inner city businesses is the key to business success. In order to achieve this objective, businesses would need to approach these inner city locations as business opportunities and to forge relationships with businesses and people located there. The government’s role would be to develop a strategic approach to developing an area’s infrastructure and to funding economic development programs.

Thus while Porter (1995) posited that the chief advantages of inner city businesses were: strategic location; local market demand; integration with regional clusters; and motivated human resources. Businesses in distressed areas have their own special set of concerns.

Examples include: lack of economic engines; limited access to marketing and capital; safety and security; education, and viable leadership.

### **Microenterprises**

Another current approach to economic development focuses on microenterprise in a low-income area. According to this view, a small business owner, operating from a low-income household could experience such benefits as: increased financial assets; increased flexibility in order to manage financial responsibilities; and personal growth, autonomy, and new business prospects (Sherraden et al., 2004). These positive outcomes help to establish the foundation for a successful entrepreneurial experience in a distressed area.

Challenges inherent in this form of entrepreneurship include: only modest increases in income; lack of business knowledge and experience; and lack of capital; long hours, stress, and insecurity (Sherraden et al., 2004). As a result, business owners may revert back to traditional forms of employment.

Over time microenterprise programs have been developed to reduce some of these barriers to success. Typically, a microenterprise development program (MDP) includes: business training, particularly in the area of financial management; counseling and support to deal with job demands and challenges; and networking, in order to forge important relationships among other business owners, and other important contacts such as representatives from educational institutions, banks, local government, and economic development groups. Various programming elements then attempt to focus on the critical needs of the new entrepreneur.

Studies examining the performance of microenterprise programs have identified characteristics

that appear to be critical to success. Servon and Bates (1998) found that well-educated, skilled, and experienced entrepreneurs were more likely to be successful than less skilled counterparts.

While the educated group may not fit one's impression of the typical entrepreneur in a distressed area, they may represent a significant segment of the population.

Sherraden et al. (2004) suggested that modeling and experience might be a more accurate predictor of success. Other important variables included nontraditional types of businesses rather than the more typical small retail and personal service forms and participation in a large scale business operation (Servon and Bates, 1998). Bailey (1993) reported that financial assistance in securing loans for ambitious and talented participants and emotional support for them were critical activities. Sherraden et al. (2004) supported these findings and also identified thoughtful goals and a good market as being important. Bailey (1993) identified factors that impinged on the success of the program participants, the major one being government regulations dealing with public assistance that served to penalize the entrepreneur during the critical startup period. Business loans and capital equipment were included in the evaluation of personal assets and could result in a loss of benefits.

According to Sherraden et al. (2004), "business decline is associated with poor product choices, a poor local economy, poor business skills, and lack of business infrastructure, especially access to markets and transportation (p. 124). Overall, the literature reveals that there is a complex web of issues that need to be addressed by participants, educational institutions, established businesses, and government in order to achieve success in inner-city entrepreneurship

## **Incubators**

Incubators attempt to increase the survival rate of businesses. They provide a sheltered environment for a business, with early operational costs reduced, and critical support networks are provided (Allen and Rahmen, 1985).

## **THIS WORK**

The purposes of this work were threefold: first to review the relevant literature in order to identify instructive issues, approaches, and remedies; second, to understand the nature of the firms in a distressed area and what their needs are; and third, to provide intervention assistance that would help to ameliorate their condition, if needed, and thus support strategic economic development of the neighborhood.

## **METHODOLOGY**

Spokane, Washington's East Central Neighborhood was one of the first entitlement neighborhoods for HUD Community Development Block Grants (CDBG) in the city, and remains an urban neighborhood with extreme poverty, high crime, low business success rate, and low employment levels. As a result of a recent HUD grant

([http://66.102.7.104/search?q=cache:MvhII\\_tUeVEJ:eastcentral.spokaneneighborhoods.org/documents/](http://66.102.7.104/search?q=cache:MvhII_tUeVEJ:eastcentral.spokaneneighborhoods.org/documents/), March 9, 2005) community leaders in collaboration with the city and local colleges and universities identified three critical need areas: 1) workforce development and job training; 2) business development and sustainability to promote job creation and retention; and 3) neighborhood revitalization through the development and adoption of a neighborhood plan which addressed the issues of poverty, housing, community facilities, and services within the neighborhood.

The College of Business and Public Administration's Business Resource Center at Eastern Washington University developed a survey questionnaire in order to link neighborhood businesses and their training needs; to establish a basis for communication necessary to respond to their needs; and to develop a neighborhood business profile in order to identify broader issues of the business community.

In order to support the overall goal of the survey, questions were designed to address issues in key areas: demographic data, neighborhood marketing, employment and hiring, and neighborhood concerns. Demographic data included: firm size, firm age, property ownership, and measures of business success such as use of business plans and e-commerce.

To define their marketing activities and strategy, there were questions relating to marketing reach and short and long-term goals. Questions concerning employment and hiring addressed whether or not the business owners hired from their own neighborhood. Lastly, business owners were asked to: define the problems they saw in their neighborhood; suggest solutions; describe their knowledge of neighborhood organizations; and state if they would participate in neighborhood revitalization activities.

Respondents were solicited via direct mail to approximately 1400 known business addresses and by personal interviews. Fifty-eight businesses responded to the initial mailing, and an additional twenty-five through direct interviews. The researchers attempted to reach a broader constituency by a second direct survey of targeted business districts within the neighborhood and fifty-six additional surveys were obtained. A total of 139 surveys were returned from the East Central Neighborhood of Spokane, Washington, presenting a

| 9.3% response rate. While non-response error and a sample not being representative of the population, the results of the survey are similar to those reported in many research papers.

## RESULTS

The results indicated that the East Central businesses surveyed are small, with 56.8% having less than six employees, and only one having 100 employees (Figure 1).

---

Insert Figure 1 about here.

---

Thirty-seven percent (36.7%) have been at their present location for one to five years, with 13.7% having survived for over twenty-five years (Figure 2).

---

Insert Figure 2 about here.

---

Nearly forty-two percent (41.7%) reported that they owned their business property. When asked about business planning 61.2% said that they had a business plan. When questioned about e-commerce, 31.6% indicated that they have a webpage, and of those 86.4% used it to promote a product. Most East Central businesses (65.5%) had a regional marketing focus, compared to 56.8% that had a local market focus (Table 1).

---

Insert Table 1 about here.

---

When asked about business strategy and goals most said that their highest priority was to introduce new products; 22% are thinking about expansion in the short term, and 28% in the long term. Nine percent of the businesses were considering a move out of the neighborhood in the near term, and 13.7% in the long term (Figure 3).

---

Insert Figure 3 about here.

---

Fifty-nine percent of East Central businesses surveyed reported that they did not hire from the neighborhood, while 5% said they hired entirely from the neighborhood. Over 57% indicated that they do not plan to hire in the next six months, while 38.8% said they would. Additionally, 73% answered that they could not find trained employees in the neighborhood with teamwork skills as the most needed attribute followed by communication skills (Figure 4).

## **DISCUSSION**

How does one break the cycle of poverty in a distressed neighborhood? One government funded direction was “welfare to work.” Microenterprise programs were another (Schreiner, 1999). A third had to do with planting small business incubators in distressed areas (Allen and Rahmen, 1985) leading to self employment (Dennis, 1996). Certainly distressed neighborhoods suffer from familiar challenges that developing countries face: lack of economic engines, poor access to education, lack of access to marketing channels, and low and no capital. Studies have shown that the segment of the population that benefits from

government sponsored programming are the better educated middle class that take advantage of the programming (Schreiner, 1999; Servon and Bates, 1998), taking profit from the neighborhoods and not creating significant numbers of new jobs. Further, education is identified as an important ingredient of future change for distressed area citizens (Bates, 1998).

Consistent with previous research (Schwartz et al., 1990) little has changed over the years. The major implication for distressed neighborhoods continues to be that any form of economic intervention, but without the right combination of owners, business types, and a healthy local economy that has not yet permeated the distressed areas, there is continued failure. The firms in the present study are largely survivors, and have maintained, but that does not help the area grow and prosper.

The business owners themselves provided some insight into the character of their neighborhood and the changes they would like to see. When asked about safety issues in the neighborhood, the replies overwhelmingly indicated that personal crimes were an issue. Drugs and prostitution were mentioned most frequently, and problems with transients and the homeless were second and third respectively. According to business owners, streets and related maintenance issues were a major concern in the neighborhood, followed by general cleanup. They indicated that they wanted a cleaner and more appealing looking façade. Other responses in this category ran the gauntlet, but generally indicated that the look of the neighborhood was important to attracting and keeping business.

While the survey results lend support to general strategies for neighborhood revitalization: 1) stabilize existing businesses and help them grow; 2) recruit new

businesses to the neighborhood; 3) identify and help those in the neighborhood grow new ventures, problematic is the failure of the firms to grow and the low numbers of neighborhood residents as employees coupled with the lack of interest in educational experiences that the literature indicates is critical for viability and growth. Most of the concerns then, were tactical in nature.

One result was that in the distressed neighborhood firms were generally smaller compared to the rest of the nation's firms in similar industry (NAICS) codes and the firms that had been there the longest were the smallest. The firms survived but were also not growing. Perhaps they were no-growth companies and adding more of the same type of firms with the same type of owners will not improve the economic conditions in the neighborhood.

On business planning, academic research has demonstrated that those businesses with business plans have better success rates and higher revenues. While over 60% of the respondents had a business plan, there was no strong statistical relationship between firm longevity and having a business plan. Again, though these were survivor firms. Perhaps business planning was helpful in maintaining the firm.

On e-commerce, while over 60% of the firms in the U.S. now employ e-commerce, due to the nature of the respondent firms and their goods and services or the lack of skills of the business owners related to e-commerce, only slightly over 30% of the firms reported that they maintained a webpage. The majority of the remainder indicated that they would like to use e-commerce. In addition to assistance in getting on-line and utilizing e-commerce, additional research is needed to determine the lack of interest in e-commerce.

On job creation and utilization of neighborhood residents in area businesses, almost 60% of the surveyed firms do not hire from the neighborhood. This could be due to many issues and is a topic for further study. If growing firms in a neighborhood do not result in neighborhood jobs, then how are the distressed neighborhoods helped? Bates (1989)

suggested that unless capital and education are provided in low income areas, business growth will be stultified in inner cities in the U.S. While much progress has been made in the provision of microenterprise and inner city support, development of firms in distressed areas remains a challenge, as the current study again demonstrates.

Servon (1998) discussed the importance of microenterprise programs and their networking impact on social capital. She suggested that while the networking itself was not sufficient, it was necessary to being the turnaround of the neighborhood. As a result of the networking, both internal to the stakeholders, and external to the neighborhood, recent attention has been paid to the neighborhood in terms of a potential \$100,000 reward for its efforts in the social and economic development of the area. This result supports Servon's argument. The full impact on the neighborhood firms remains for the future.

### **SUMMARY/CONCLUSIONS**

Nowak (1977) concluded that successful economic development in distressed areas is supported by appropriate public, private, educational partnerships that serve to impact the areas. Thus, without such partnerships, success will likely be more happenstance than circumstance. The local area studied had no over-abiding strategy in place. It is likely that the poor will continue to remain poor until at least a strategic focus for economic development is realized and then continued network support remains in place.

“Exulting the ‘hidden’ strengths of inner city businesses and locations is not enough to increase sales and job growth within these neighborhoods” (Weber and Schell, 2003 p. 162), contrary to what Porter postulated in 1995 (Porter, 1995). The authors found that simply facilitating networking to couple inner city firms with their ‘locational advantages’ to larger partner firms was not sufficient. Rather, they found that minority firm contacts for the large firms were an important adjunct of their work and that important linkages could be made. Of the firms studied by Weber and Schell (2003), their reasons to remain in their neighborhoods were similar to those found in this work, i.e., undercapitalization, inertia, etc. These firms were not “the beacons of growth (Weber and Schell, 2003 p. 162)” with related job creation that governments and foundations focused on for economic development hoped for. The present research results are similar.

Perhaps the conclusion is that some self selection for change is important and no matter what the nature of outside interventions is applied, only those firms that care to change will change. While not a pleasant thought, perhaps programming should only then be available to those who seek it out, and only provided as a broad brush stroke of intervention by those having the funding to support such widespread inner city development. However in the U.S. citizens are dedicated to helping those who have difficulty helping themselves, and while the reality of distressed neighborhood outcomes may continue to be distressing, helping is the “right” thing to do.

A major “bright” spot of all the neighborhood activity is the very focused group of citizens, governments, educational institutions, and outreach organizations that may

very well serve to change in a very positive way the overall neighborhood for the good of an entire city and region. That change will be the subject of a future paper.

### **IMPLICATIONS**

Results of this study are important because they suggest a means to bridge the gap between two theoretical approaches, cluster development and microenterprise development. One can recognize that there is value in small business ownership for individuals in the form of personal freedoms: improved income, independence, and flexibility. By meeting the needs of entrepreneurs and small business owners through education, training, counseling, and networking, as well as attempting to improve the general environment through crime prevention strategies, one can encourage the success of the individual small business. Importantly, a series of individual business successes, coupled with an improved business environment, where education, communication, safety and security, and partnering among public and private agencies is developed, could create a contagion effect for further economic development. On a practical scale, the study provides further elucidation of urban economics as well as the impact on an area providing some direction to those who seek to change similar distressed neighborhoods.

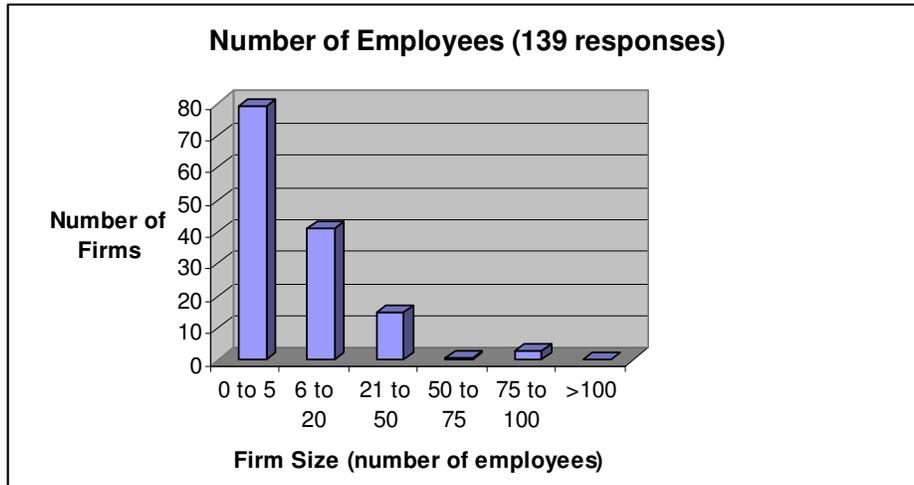

### **ACKNOWLEDGEMENTS**

Special thanks to our Urban Planning Department colleagues (Professor Dick Winchell in particular) who brought us into the East Central activity; Jerry Numbers, East Central Committee Chair et al. who welcomed us; and Ms. Rhosetta Rhodes, of the Community Colleges of Spokane, who has directed the entire program. This activity was and is an overall community activity with many important players, *the most important of all are the East Central people themselves.*

# **THE INVESTMENT DECISION-MAKING PROCESS IN SMALL MANUFACTURING ENTERPRISES: THE CASE OF PRINTING AND CLOTHING INDUSTRIES IN THE UK**

**IGNATIUS EKANEM**

Middlesex University Business School, London

## **ABSTRACT**

*This study is concerned with the investment decision making process in small manufacturing enterprises in the printing and clothing industries. The focus is on the actual decision-making behaviour of owner-managers, using 'Insider accounts' as a qualitative methodology which involves in-depth, semi-structured interviews and direct observation, conducted longitudinally in 8 case study companies. It is a research method which includes detailed accounts from the actors themselves, incorporating the actual motives and behaviour of owner-managers based on the philosophy that the 'objects' studied are in fact 'subjects', who produce accounts of their world.*

*The results suggest that owner-managers use 'bootstrapping' techniques for their investment appraisal instead of formal methods recommended in the financial management literature. 'Bootstrapping' represents an approach to decision making that is grounded in previous experience of key decision makers and their organisations and the largely informal routines that they develop from this. By which owner-managers rely on experiential learning when making investment decisions, rather than formalised methods. As a result, conceptualising small firm investment decision making within the context of an organisational learning approach holds promise as an explanatory framework for investment behaviour in small firms.*

## **INTRODUCTION**

Despite the increased attention paid to owner-managers in the small firm sector, little is known about the process of financial management and decision-making in small firms and the entrepreneurship process (Deakins, Morrison & Steel, 2000). This paper attempts to shed light on the process issue by investigating how decision makers in small manufacturing enterprises behave compared with what the theories and the literature have suggested about investment decision-making. It uses a methodological approach that incorporates the actual motives, values, beliefs and intentions of owner-managers. To understand fully the process of investment decision-making in small firms, it is necessary to understand first the barriers faced by these firms and the motivations of owner-managers. These barriers are inherent in the small firm sector and range from limited resources (including investment finance and managerial expertise) to varied objectives and the concentration of decision making in the hands of one or two owners, who are closely involved in the day to day operation of the business (Burns, 1996). It is also necessary to understand the uncertain and risky nature of the small firms' operating environment (Jarvis, Kitching, Curran & Lightfoot, 1996) since investment decisions must not be considered in isolation of the barriers faced by these firms (Pike & Neale, 1993).

This paper examines the motivations and informalities of owner-managers as a logical first step to understanding the actual investment decision-making behaviour in the context of small firms. The core finding in this paper is that small firms use 'bootstrapping' techniques (Winborg & Landstrom, 2001) in their investment decision-making instead of formal methods recommended in the financial management literature. These are largely informal routines providing 'satisficing'

solutions, which although not explicitly rational, are boundedly rational. In other words, they are rational within the context of owner-managers' perceptions, knowledge and experience.

In this context the more specific aims of the paper are to:

- analyse the investment decision-making process of small manufacturing enterprises and to assess the methods actually used in relation to those that could be used.
- assess the extent to which investment decisions in small firms are based on previous learning experiences of decision makers.

Following a review of previous literature and methodology employed in the study, the findings from 8 case studies is presented. The final section summaries the main themes emerging from the findings.

## LITERATURE REVIEW

### Investment Appraisal

The search for reliable techniques for investment decision-making is currently discussed in the literature as existing traditional mainstream techniques (such as discounting cash-flow (DCF) and payback) are said to be inadequate in certain situations (Akalu, 2003). These situations include the evaluation of investment in research and development (R&D) and technological innovations, mainly because of the intangible nature of the benefits involved (Irani & Love, 2002; Shank, 1996; Slagmulder, Bruggeman & van Wassenhove, 1995); and coping with the uncertainties of the environment (Akalu, 2003; Thomas, 2001). In this regard, DCF is found incomplete and may lead to decisions that destroy the value of the firm. Consequently, the management is led to select such projects on intuition, experience and rule of thumb methods (Shanks, 1996). This issue is not only a matter of concern for academics or managers but is also becoming more and more important to stakeholders of a company (Akalu, 2003).

The use of DCF, in its principal form of net present value (NPV) and internal rate of return (IRR), has been given much attention in the literature. The textbook method for establishing a business case for a project is to perform DCF analysis, using the most likely cost and benefit estimates (Thomas, 2001). In DCF analysis, the value of a project to an investor is its NPV, which is the net stream of cash flows attributable to the project, discounted at the opportunity cost of capital. The theory holds that one should pursue a project with a positive NPV (i.e. an NPV greater than zero).

The Payback method estimates the period of time taken for the future net cash inflows to match the initial cash outlay. In other words, it measures the length of time taken to recoup the original investment. Whilst theory have condemned the use of payback as misleading in making investment decisions because of its theoretical weaknesses, which include ignoring all cash flows beyond the payback period and failing to take account of the time value of money, it continues to be widely applied as an appraisal technique (Brien, 1997). Whereas more sophisticated techniques attempt to model the uncertainty surrounding investment returns, payback assumes that risk is time related; that is, the longer the period, the greater the chance of failure (Lumby, 1994).

The continuous application of traditional methods reveals significant limitations in their capacity to address the above basic problems of investment appraisal (Akalu, 2003; Lefley, 2000). Even within large firms other techniques have been proposed that can provide meaningful guidance since traditional techniques have fallen short (Graham & Harvey, 2001; Arnold & Hatzopoulos, 2000).

Such techniques include the Real Option technique, which is based on the market priced risk and return embodied in the asset value (Cho, 1996; Dixit & Pindyck, 1995). It also includes economic value added technique (EVA), which is defined as a technique that provides unambiguous metric-value upon which an entire organisation is built (Stewart, 1991). These techniques are condemned for their inability to measure the shareholder value creation in a company (Fernandez, 2001).

The above methods are based on Neo-Classical assumptions namely that the objective of the firm is to maximise profits, and that the firm operates within a perfectly competitive market. These approaches to investment decisions assume that there are capital projects to be appraised; that cash flows from projects aim to maximise owners wealth; that management always act in the owners' best interest; that the future cash flow can be isolated/estimated; and that cash flows are discounted at the opportunity cost of capital. However, this type of literature hardly deals with how projects are generated and why projects are considered. It is usually assumed that there are capital projects to appraise (Shank, 1996).

These problems are even more acute in the small firm context than in large firms. Firstly, the small firm's financial and operational environments are more unstable (Jarvis et al, 1996). Secondly, the investment decision-making of small firms may be more influenced by behavioural factors, focusing on what firms actually do, with organisational perspectives including the influence of firm characteristics (Deakins et al, 2000). These approaches are referred to as the behavioural/organisational theories of the firm. The behavioural theory of the firm states that a firm is a coalition of participants with disparate demands, changing foci of attention, and limited ability to attend all organisational problems simultaneously (Cyert & March, 1963). Organisation theory is an extension of the behavioural theory of the firm which places considerable emphasis on the study of processes i.e. what goes on in an organisation, and the organisational decision-making processes (Cyert & March, 1963).

Unlike neo-classical theory of the firm, the behavioural and organisational approaches emphasise that, in fact, the firm is a complex organisation where information is far from perfect, with decision makers possessing varying abilities and a range of motives with both economic and social dimensions that cannot so easily be reduced to a simple profit maximisation motive (Spence & Rutherford, 2001). It is argued in this study that in small firms (whether it is a one-person firm or it has other employees) there are various interest groups such as the stakeholders who have legitimate interests in the activities of the firm and a good deal of influence in how it operates, and therefore there is an organisational aspect to decision-making.

The core argument in this study is that although the behaviour of small business owners is not explicitly rational, it is boundedly rational because their knowledge is acquired through experience and the learning process, and their actions and decisions are also based on what they have learned through experience and interaction with stakeholders. In the literature, this process is referred to as organisational learning.

### **Organisational Learning in Small Firms**

Organisational learning is one of the neglected areas of the small firm research (Chaston, Badger, Mangles & Sadler-Smith, 2001). Consequently, Deakins (1998) argues that our knowledge and understanding of the interaction of learning and the entrepreneurship process is limited. The ability of the owner-manager to learn from decisions, from mistakes, from experience and from their networks is crucial to their decision-making behaviour and the ability of the small firm to survive

(Gibb, 1997). This type of learning entails not only reacting or adapting to the environment in order to cope with it and survive but it also entails "generative" learning which embodies the capacity to create and 'bring forward' experience, rather than wait for (and learn from) it" (Gibb, 1997, p.17). Organisational learning involves the acquisition, distribution, storage and interpretation of information (Boussouara & Deakins, 2000). Thus, learning does not necessarily have to result in changes in behaviour, rather it offers the potential to behave differently (Cope & Watts, 2000). Polanyi (1967) distinguishes between tacit knowledge or implicit knowledge which is not codified and explicit, formal knowledge which is codified.

Therefore, learning in small firms is a complex process of continual trial and error (Williams, 2001). It is often unintentional, incidental or accidental (Matlay, 2000b). It is also a process of learning from peers; of learning by doing; of learning from feedback from customers; of learning by copying; of learning by problem solving and opportunity taking; and of learning from mistakes (Gibb, 1997).

## **METHODOLOGY**

In recent years there has been an increasing call for a greater use of qualitative methodology in small firm research. This study uses qualitative methodology because it is about the study of decision-making process (Deakins et al., 2000; Gummerson, 1991) and because the 'how or 'why' questions are being asked about contemporary set of events over which the researcher has little or no control (Yin, 1994). Gibb (1997) argues that objective studies of business requirements using questionnaires and check-lists, and generally positivist-type approaches, do little to help answer the basic questions relating to process. Without answering these questions it is impossible to recommend how practices can become more effective.

Moreover, a qualitative methodology, based on detailed accounts of the actions of owner-managers, was judged to be the most appropriate since the aim of the present study is concerned with investigating the process of investment decision making within the context of organisational learning. The behaviour and actions of owner-managers as they occur in everyday life were also observed (Curran & Blackburn, 2001; Shaw, 1999). Therefore, in order to develop an understanding of the process and capture the 'full range of data nuances and conditionality' when decisions were actually being made (Mason & Rogers 1997, p.31), a strategy known as 'insider accounts' was developed and used as the appropriate qualitative research method (Hammersley & Atkinson, 1995).

As operationalised in this study, 'insider accounts' involved in-depth, semi-structured interviews and direct observation, conducted longitudinally in 8 case study companies. The philosophy underpinning 'insider accounts' is that the 'objects' studied are in fact 'subjects', and they themselves should produce accounts of their world. Therefore, 'insider accounts' can provide a basis for understanding the behaviour of small firms and the motivation of owner-managers, thus helping to answer basic questions relating to process. An important feature of the approach is its capacity to elicit descriptions, explanations, and evaluations of every aspect of owner-managers' actions. Thus, 'insider accounts' generate owner-manager's knowledge which can be tapped and treated as the basis of an alternative conception of appropriate techniques for smaller businesses.

## **EMPIRICAL EVIDENCE AND DISCUSSION**

The term 'process' is used in this study to mean how and why decisions are made. It involves identifying key elements in decision-making and how they interrelate with each other. The

analysis of the evidence suggests that investment decision in small manufacturing enterprises involves mainly the evaluation of alternatives and the choice of alternatives, although in practice, these elements are not necessarily separately identifiable.

### **Evaluating Alternatives**

A key element in the investment decision-making process in small firms in the study was the evaluation of alternatives. Evaluating alternatives involved comparing the specifications of all the machines involved, as well as the resale value of the machines and their relationship to the development strategy of the business. This process typically included attending demonstrations, which provided an opportunity to see the specifications and prices of equipment, as well as to talk to other people in the industry and to learn from their experience. This is captured by the owner-manager of Company 2's description of the investment decision-making process of his company:

*"We attend demonstrations and talk to other people in the industry to know what they have got and what problems they have had".*

This analysis also established that demonstrations also provide the opportunity for a 'trial run' of the work the machine would be used for. An extract from a tape-recorded interview with the owner-manager of Company 3 provides an insight into this process:

*"At demonstrations we take what we consider to be the most difficult job and ask them to do it on the press for me and the operator to see how it works and how the various components work. If it looks okay and does what we consider to be a difficult job easily that goes to prove that it is a good machine".*

Therefore, from the above quotes it can be seen that investment evaluation in the case study firms was based more on the technical reliability of the equipment rather than the cost-benefit analysis suggested in the literature. This is mainly because, for a small business owner, equipment must be technically reliable, easy to maintain and capable of producing good quality products. In other words, the informality is appropriate to needs and encourages flexibility. It not only seems to work, but it is effective and based on learning by doing rather than something which is formally taught. The usefulness of attending demonstrations is illustrated by the following comments from the owner-manager of Company 3 during the third interview:

*"You learn a lot from demonstrations, from the experience of the suppliers. The ability to stand back to see what the machine can do is very important and very useful".*

This owner-manager believes that the underpinning knowledge gained in taking part in demonstrations has been critical when faced with 'real life' incidents and, importantly, believes that it enables him to reflect and intellectualise any learning that took place.

### **Choosing From Alternatives**

Another element of the decision-making process is choosing between alternatives. For non-routine investment decisions, owner-managers typically relied on feedback from customers, as well as on technical advice from equipment suppliers and machine operators. The respondents

cited examples of how they had learned skills and insights from stakeholders, particularly equipment suppliers and key employees.

*(i) The role of customers*

The ability of owner-managers to respond speedily to customer demands was particularly important in the printing sector. In Companies 1 and 2, for example, customers increasingly wanted just-in-time printing which required the acquisition of new technology equipment, including direct digital colour and computer-to-plate (CTP) equipment, which were expensive, compared to clothing firms where equipment typically cost much less. In some of the clothing firms, the influence of customers on investment decisions was direct, when equipment was purchased to meet the needs of specific customers. For example, in Company 6 the bulk order for casual wear required the use of twin-needle machines, which the firm did not previously have but was compelled to acquire. In the 'cut-make-and trim' (CMT) clothing firms, a subcontract relationship existed with customers, which involved major customers having a direct impact on investment decisions, when the changing requirements of major customer affected long-term bulk contracts, with possible implications for the equipment required.

Learning from customers took place through a continuous feedback process between customers and management. This was the case in Company 5 where the owner-manager was able to ascertain the standard of the quality of their products through feedback from customers, which in turn determined the need for their investment. Thus owner-managers learned from customers as part of a network and use them to scan the wider business environment and to define, meet and bring forward their future needs (Gibb, 1997).

*(ii) The role of equipment suppliers*

The role of equipment suppliers in the investment decision-making process became clearer by the time of the third visit, because initially some owner-managers denied that equipment salesmen were an important influence. For example, the owner-manager of Company 1 (as well as others) initially denied receiving advice from equipment suppliers, but in the third interview when he 'opened up', it became apparent that their role was considerable. With new technology assets, such as CTP and direct digital colour presses particularly, the owner-manager of Company 1 was found to rely more on the equipment supplier in terms of seeking information and assurances, than in the case of conventional equipment because they were much less familiar with digital printing technology. This liaison is conceptualised in this study as a learning process where the owner-manager draws from the experiences of others because he is not familiar with the situation. Equipment suppliers are much larger companies than their customers and therefore are able to invest in research as digital printing technology is still being refined (Smallbone et al, 2000).

The owner-manager of Company 1 revealed the extent to which the advice received from equipment suppliers was useful after the purchase of the 'computer-to-plate' (CTP)<sup>1</sup> equipment. He revealed during the third interview that he had not only learned from the experience of the equipment suppliers, but that their advice actually fed into the choice of alternatives. The owner-manager explained:

*"They helped tremendously not only by providing us with advice about the CTP but also by providing technical support and training. They 'll probably continue to offer us with the benefit of their experience for a long time".*

This illustrates a continuous learning process, which has been identified as a key influence of competitive success (Sullivan, 2000). When asked specifically about what was learned from the equipment suppliers the owner-manager emphasised:

*"The advice and support gave us more confidence when we were going to buy our B2 Xeikon digital press. Our heavy dependence on them (equipment suppliers) has lessened as we now feel more able to cope with the technology ourselves. I now feel more confident to make these decisions myself".*

This owner-manager believes that the skills and knowledge gained in taking advice from equipment suppliers during the purchase of the CTP had been critical when subsequently faced with the purchase of the B2 Xeikon digital press<sup>2</sup>. He believes that the advice enabled him to dissect, reflect, learn and act on the critical incident, thus leading to a change in behaviour.

### *(iii) The role of key employees*

There were varying degrees of involvement of key employees in all stages of the investment decision-making process, but was prominent at the evaluation stage, when key employees would attend demonstrations with owner-managers to check out equipment specifications and prices. They also inspected equipment in action in an ideal working environment with owner-managers to determine their technical reliability. This emphasises that investment appraisal did not involve cost-benefit analysis but rather simply appraising whether or not the equipment could do the job that it was supposed to do. In other words, the process was a technical appraisal rather than financial appraisal.

Whilst the management style of owner-managers often tends to be autocratic and underpinned by a reluctance to delegate decision-making (Burns, 1996), key employees in Companies 1, 2 and 3 in the printing industry and Company 5 in the clothing sector were substantially involved in the investment decision-making process. The owner-manager of Company 1 indicated that he, together with the production manager, inspected equipment in an ideal or working environment:

*"We [the owner-manager and the production manager] go and see some demos and look at different pieces of kit...and think, well, will it work for us?" [Owner-manager - Company 1].*

The above claim was verified in a separate interview with the production manager. His involvement in the decision-making process is demonstrated in the following extract:

*"We [the production manager and the owner-manager] go and look at different pieces of kit and then we say which one will slot in the easiest into the way we work already, and how much time is it going to take us to get us up and running on it and working a 100%" [The production manager - Company 1].*

The above extract from the interview with the production manager illustrates the nature of the feedback process and the extent to which his opinion and assessment was actually taken into

account. The use of the word 'we' by both the owner-manager and the production manager in the above quotes suggests a form of 'collective activity' (Wyer et al, 2000). The extent to which the opinion of the production manager was taken into account was apparent when the owner-manager revealed a "*major incident*" that took place a couple of years back where he, contrary to the advice of the production manager, purchased a fully computerised Dainippon Camera<sup>3</sup> for £18,000 which is hardly ever used. The owner-manager recalled that at that time he had the problem of recognising and trusting the ability of key employees. The result was that the owner-manager not only made a poor investment decision, but the business suffered because of the tension, confusion and the internal conflict that the situation created. The owner-manager reflected on the situation and how he has learned from it:

*"I have learned to trust him basically and to recognise that he is a huge asset to the company. I don't ignore him any more. I have come to respect his views and opinions, I have completely changed"*.

This owner-manager has actually learned from his mistakes and has changed (Gibb, 1997). He has now learned to delegate and to trust his key employees for their technical expertise.

## CONCLUSIONS

The findings in this study revealed that what the owner-managers were actually doing was finding their own solution to a problem. They did this by using an approach that may be characterised as 'making do' or 'patching things' together, where instead of using established methods or procedures they found ways round problems. This approach is conceptualised in this study as 'bootstrapping' techniques (Winborg & Landstrom, 2001). Bootstrapping represents an approach to decision making that is grounded in the previous experience of key decision-makers and their organisations and the largely informal routines that they develop from this. The concept of bootstrapping is not simply a way of owner-managers finding a solution to a problem or a sort of 'fire-fighting', it is a notion of what they are bringing to solve the problem i.e. reliance on past experience. In this sense, bootstrapping is a form of learning behaviour. It is essentially a trial and error learning process which brings knowledge, skills, values and attitudes together and provides owner-managers with an opportunity to evaluate outcomes associated with investment based on previous experience.

Although not a policy paper, the evidence presented here does have some implications for policy. The evidence suggests that rather than focusing on formalised training courses teaching prescriptions, a more productive approach might be to place entrepreneurs into potential learning situations. This means creating a decision making environment which is sensitive to the motives and values of owner-managers. It also involves gearing training activities to practical problems, tailor-made and specific to the business in an informal manner.

## NOTES

1. CTP is a printing press that enables digital input into the plate-making process and speeds up the workflow between pre-press and press.
2. B2 Xeikon digital press is a direct digital printing press that allows digital pre-press information to flow directly to the press, facilitating variable image printing for just-in-time (JIT) short-run personalised jobs.

3. Dainippon Camera is a fully computerised camera with 'densometer' checking for halftone values used for taking pictures of design and artwork.

MBA Student, Research Assistant - Simmons School of Management

The multiplication of Entrepreneurship Teaching Programs (ETP) and the increasing level of resources allocated to these initiatives has generated a growing interest from funders and academics about the effectiveness and efficiency of ETP programs as well as the identification and diffusion of best practices. Realizing the underlying complexity of ETP program assessment, several researchers have explored new and alternative methods to program evaluation, taking into consideration direct programmatic impacts, such as new venture and job creation, as well as indirect impacts (increasing entrepreneurial spirit) on economic development. According to several studies, limiting the evaluation of ETPs to direct micro-economic impact (new venture and job creation) can often be misleading and short-sighted. Because the impact of these programs on participants is diversified across several disciplines, industries, and markets, the effectiveness of ETPs may not be readily or immediately apparent.

Furthermore, ETPs can vary widely across countries and educational institutions, in terms of short term objectives, target audiences, format and pedagogical approaches. For this reason, a need exists to design and develop a common framework to evaluate, compare, and enhance the structure of those programs. The proposed framework should include both a set of clearly identified criteria and a methodology for effective measurement. At the same time some authors underscore the need for developing new assessment indicators (Moro, Poli and Bernardi, 2004; Hytti and Kuopusjärvi, 2004).

Based on these observations, our paper will present a study of a new methodology designed for ETP assessment. This methodology will use the theory of planned behaviour (Ajzen, 1991 and 2002), as described by Fayolle (2005). The first study was reported by Fayolle and Gailly in 2003. The objective of our research is to apply our theoretical and methodological framework to

an study consisting of a 3-day- pedagogical process, with a sample of 275 French students working on a Specialised Masters in Management.

Our research sample is composed of students who recently started a one-year specialised management program at a business school ranked among the top four in France. This business school has been promoting and diffusing the entrepreneurial spirit throughout its program and curriculum over the past twenty years. Before attending the specialised masters, students have received a degree at the Master of Science level, usually in technological disciplines from French engineering schools and technological universities.

At the beginning of the masters program, students are intensively trained for several weeks to acquire fundamental managerial skills and competencies. Upon completion of this portion of the program, they are trained and educated according to their chosen specialty. During their first weeks in the masters program students are all engaged in a 3-day case study related to entrepreneurship. We have used this pedagogical event as a study for our research program, applying our methodology in a longitudinal way to capture student variation in attitudes and intentions through the 3-day program. To begin our *first phase of research*, we administrated a questionnaire at the beginning of the program, to measure attitudes (antecedents of intentions) and the level of entrepreneurial intentions. All antecedents and measures were derived from literature focused on theory and previous empirical research on intentionality.

In our *second phase of research*, we administrated the same methodological conditions in a follow-up questionnaire to measure the same variables, with a specific emphasis on assessing the influence of the pedagogical process on the eventual variation of entrepreneurial intentions.

The results have been analysed for the entire group as well as through a segmentation of the sample into sub-groups based on various factors influencing entrepreneurial intention.

In a first section of our paper, we study the entrepreneurship literature dealing with issues of ETP impact. The second section presents our theoretical approach which is based on the theory of planned behaviour. It is important to note that the theory is used not as a predictor of the entrepreneurial behaviour, but as a powerful model of conceptualising entrepreneurial intention and its antecedents. The third section describes the details of our study, including the sample and the research material. It also presents and discusses our results. In the conclusion, we develop the theoretical and practical implications of the research, commenting on its limitations and avenues for future research.

## **1. THE IMPACT OF ENTREPRENEURSHIP EDUCATION PROGRAMS**

Throughout the world, student interest in entrepreneurship as a career choice is growing (Brenner et al., 1991; Hart and Harrison, 1992; Fleming, 1994; Kolvereid, 1996), while interest in traditional professional employment in big business is gradually declining (Kolvereid, 1996). The orientations and behaviours of students and young graduates are influenced by a number of personal and environmental factors (Lüthje and Franke, 2003). Empirical research has shown that the presence of entrepreneurship education programs (ETPs) and a positive image of entrepreneurs within the university are both incentives for students to choose an entrepreneurial career. Johannisson (1991) and Autio and al (1997) underscore the impact of students' perceptions of entrepreneurship,, along with resources and other support mechanisms available in the university environment, on positively influencing student attitudes towards entrepreneurial careers. Other research has shown the importance of the social status of entrepreneurial activities and situations (Begley and al., 1997) and the statistical link between the level of entrepreneurial intention and the number of management courses taken by students enrolled in other programs (Chen and al., 1998).

Entrepreneurship education and training influence both current behaviour and future intentions (Kolvereid, Moen, 1997; Tkachev, Kolvereid, 1999; Fayolle, 2002). In other words, there are significant differences between students who have taken entrepreneurship courses and those who have not. However, the question is if the causal relationship between the educational variables (course content, teaching methods, teacher profile, resources and support, etc.) and the direct intentional and/or behavioural antecedents (attitudes, values, knowledge, etc.) can really be explained in detail? While findings of researchers who have attempted to do this are summarized below, we still believe there is a need for further conceptualization and testing.

Attempts have been made to compare the intentions and/or behaviours of students from different groups. For example, Varela and Jimenez (2001), in a longitudinal study, chose groups of students from five programs in three universities in Columbia. They found that the highest entrepreneurship rates were achieved in the universities that had invested the most in entrepreneurship guidance and training for their students.

Noel (2001) looked specifically at the impact of entrepreneurship training on the development of entrepreneurial intention and the perception of self-efficacy. The students in the sample had all taken an entrepreneurship education program and were graduates in entrepreneurship, management or another discipline. Noel's findings at least partially confirmed the assumption that the entrepreneurship graduates were more likely to launch businesses and had a higher level of intention and a more developed perception of self-efficacy than students in the other two groups.

Other researchers have tried to explain the relationship between entrepreneurship programs and individual characteristics, such as need for achievement and locus of control (Hansemark, 1998) or the perception of self-efficacy (Ehrlich and al., 2000). They found that entrepreneurship education had a positive impact, enhancing these characteristics and the likelihood of entrepreneurial action at some point in the future.

However, less attention has been paid to educational variables. Dilts and al. (1999) attempted to show that certain teaching methods (traineeships and field learning) are more successful than others at preparing students for an entrepreneurial career. Lüthje and Kranke (2003) discuss the importance of certain contextual factors within the university environment which hinder or facilitate access of technical students to entrepreneurial behaviours. Their findings confirm those of Autio and al. (1997) and Fayolle (1996), which were obtained using similar samples.

## **2. THE THEORETICAL MODEL OF THE RESEARCH**

The above contributions show that it is possible and relevant to use the theory of the planned behaviour to study the emergence and development of entrepreneurial intention. Regarding specific research focusing on students, while some considered the role of institutional surroundings as significant (Autio and Al, 1997), the type of training and programs was not explicitly taken into account. Little is known about the impact of such variables connected to the formation of entrepreneurial intention, based on the antecedents of the model of Ajzen (1991; 2002).

The theory of planned behaviour is an extension of the theory of reasoned action (Ajzen and Fishbein, 1980), including the factor of "perceived behavioural control".

The central factor of this theory is the individual intention to perform a given behaviour. Intention is the cognitive representation of a person's readiness to perform a given behaviour, and is considered to be the immediate antecedent of behaviour. The first claim is that intention is the result of three conceptual determinants:

- *Attitude toward behaviour.* The degree to which a person has a favourable or unfavourable evaluation or appraisal of the behaviour in question (Ajzen, 1991). When new issues arise requiring an evaluative response, people can draw on relevant information (beliefs) stored in

memories. Because each of these beliefs carries evaluative implications, attitudes are automatically formed.

- *Subjective norms*: Perceived social pressures to perform or not to perform the behaviour (Ajzen, 1991); in other words, the subject's perception of other people's opinions of the proposed behaviour. It is possible for these pressures to have a strong or weak role in creation of intention. For example, in France, the failure of a company is often negatively perceived whereas in the United States, a person can often undergo several failures and still undertake new attempts at creating a successful business.
- *Perceived behavioural control*: Perceived ease or difficulty of performing a behaviour (Ajzen, 1991). This concept was introduced into the theory of planned behaviour to accommodate the non volitional elements inherent, at least potentially, in all behaviours (Ajzen, 2002). Krueger and Dickson (1994) show us that an increase of perceived behavioural control increases the perception of opportunity.

The model used to assess the impact of ETP is presented below (Figure 1). In this model, an ETP is assessed based on its impact on participant's attitudes and intentions regarding entrepreneurial behaviour (Fayolle and Gailly, 2003; Fayolle, 2005).

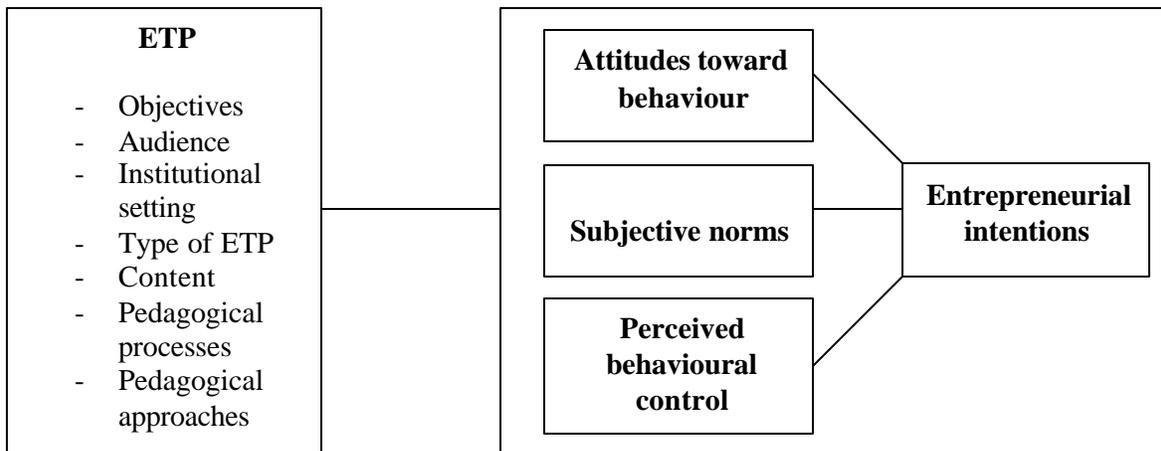

Figure 1: ETP Assessment model

In this model, the independent variables are the characteristics of the ETP that one wishes to assess or compare. These variables can be related to the ETP itself (whether or not it was attended) or to some specific dimensions related to its objectives, content (Gibb, 1988; Wyckham, 1989; Gasse, 1992; Ghosh and Block, 1993), teaching approach, audience or institutional settings (Safavian-Martin on, 1998).

In particular, Johannisson (1991) identifies five content levels for the development of entrepreneurial knowledge that can be used to characterize the content dimension of ETP: the know-why (attitudes, values, motivations), the know-how (abilities), the know-who (short and long-term social skills), the know-when (intuition) and the know-what (knowledge). Similarly, (Develay, 1992) distinguishes three dimensions of teaching approaches: content strategies, relationship strategies and acquisition strategies.

The dependent variables in the model relate to the antecedents of entrepreneurship behaviour as defined using Azjen's theory, i.e. measures of attitude toward the behaviour, subjective norms,

perceived behavioural control and intention. Those are measured through surveys of the participants completed before and after the ETP.

The key strength of this approach is that it does not attempt to assess the impact of ETP specifically in terms of specific entrepreneurial behaviour, which is difficult to evaluate because it is multidimensional, subject to delayed effect and strongly influenced by environmental factors. In particular, entrepreneurial behaviour tends to be more affected by external factors than the examples cited by Ajzen (1991), which are behaviours that can be mostly controlled by the individuals concerned. Examples of these types of behaviours include the decision to stop smoking, short-term elective preferences or the choice of whether to breast-feed a baby. The impact of the ETP is measured in terms of changes in attitudes and intentions, which are antecedents of the behaviour and for which the theory of planned behaviour and its applications provide validated measurement methodologies (Kolvereid, 1996). Furthermore, the changes in those dependent variables can then be correlated with the independent variables, i.e. the specific characteristics of the ETP considered.

This allows measurement and/or comparison of the impact of specific ETP while also testing whether that impact is affected by specific aspects of the design and/or execution of the ETP. The latter implies that this framework can be used not only to assess, but also to improve the design and execution of ETP, by linking specific characteristics of the program with particular outcomes of participant attitudes and intentions.

### **3. EXPERIMENTATION AND EMPIRICAL RESULTS**

In this section, we will present the experimentation and the main empirical results from the survey we conducted both before and after students followed an entrepreneurship training program. We describe the sample and test several hypothesis regarding the intention model and how its antecedents are effected by the ETP and student background, using standard statistical procedures (SPSS).

#### **Study**

Our study is a short-time one. It is supported by a 3-day seminar focusing on the evaluation of new venture projects, mainly through their business plans. This seminar aims to increase student awareness of entrepreneurship and to help them understand some main issues in relation to entrepreneurs and their own entrepreneurial projects. The seminar covers many of the key dimensions of the entrepreneurship and specifically the context of new venture projects. Students work in small groups (4-5) and interact with entrepreneurs and professors specializing in entrepreneurship, during the seminar.

At the beginning of the program, we administrated a questionnaire to the 275 participants in order to capture their attitudes and measure the level of their entrepreneurial intentions. As discussed earlier, we used measures derived from social psychology literature. At the end of the 3-day program, we measured these same variables in similar methodological conditions.

The two questionnaires (before and after the ETP) were sent to 275 students and included 47 Likert-scaled items related to the parameters of Ajzen's intention model (attitudes towards the

behaviour, subjective norms, perceived behavioural control and intention) and 23 questions related to the students background (age, gender, entrepreneurial experience, etc.). Our research material is derived from the questionnaires developed and validated by Kolvereid (1996), for the measure of the parameters of Ajzen's intention model. Each item is scaled from 1 to 7 and different model parameters are measured as the average score of a predefined set of items.

As stated above, the research material also included items related to what is usually called "demographic" variables (Robinson et al., 1991) and students background variables (previous entrepreneurial experiences and exposure). Finally, we also measured the extent to which entrepreneurial knowledge and skills are acquired by participants, using a specific approach developed by Johannisson (1991).

### **Sample analysis**

Among the questionnaires, 131 answers out of 275 were incomplete or inconsistent (52% valid response rate). An answer was considered inconsistent if the standard deviation of the items related to one of the parameter of Ajzen's model was greater than 2 (given the 1 to 7 scale).

The average age of the respondents was 25 and all but 7 were French.

The main statistics regarding Ajzen's model parameters before and after the ETP are presented below:

Table 1 : Survey results.

| Measure                                       | Number of items | Average score | Standard deviation | Crombach's alpha |
|---|-----------------|---------------|--------------------|------------------|
| <i>Before the ETP</i>                         |                 |               |                    |                  |
| Attitude towards the entrepreneurial behavior | 32              | 5.01          | 0.54               | 0.86             |
| Attitude related to subjective norms          | 6               | 3.69          | 0.96               | 0.77             |
| Attitude related to perceived control         | 6               | 3.86          | 0.75               | 0.7              |
| Entrepreneurial intentions                    | 3               | 3.90          | 1.24               | 0.83             |
| <i>After the ETP</i>                          |                 |               |                    |                  |
| Attitude towards the entrepreneurial behavior | 32              | 5.00          | 1.52               | 0.87             |
| Attitude related to subjective norms          | 6               | 3.67          | 0.91               | 0.75             |
| Attitude related to perceived control         | 6               | 3.95          | 0.76               | 0.75             |
| Entrepreneurial intentions                    | 3               | 3.97          | 1.25               | 0.86             |

Before testing the impact of the ETP, we tested the validity of Azjen's model (i.e. whether the antecedents were good predictors of the entrepreneurial intention) before and after the ETP. The result of the corresponding linear regression is presented below. Please note that the measures of the antecedents were significantly correlated (correlations ranging from 0.3 to 0.6,  $p < 0.01$ ).

Table 2 : Validation of Azjen's model.

| Variable                                      | Value | Standard deviation | Significance |
|---|-------|--------------------|--------------|
| <i>Before the ETP</i>                         |       |                    |              |
| Attitude towards the entrepreneurial behavior | 0.40  | 0.17               | 0.02         |
| Attitude related to subjective norms          | 0.57  | 0.09               | 0.00         |
| Attitude related to perceived control         | 0.23  | 0.12               | 0.06         |
| <i>R-square</i>                               | 0.36  |                    | 0.00         |
| <i>After the ETP</i>                          |       |                    |              |
| Attitude towards the entrepreneurial behavior | 0.34  | 0.14               | 0.04         |
| Attitude related to subjective norms          | 0.56  | 0.06               | 0.00         |
| Attitude related to perceived control         | 0.27  | 0.10               | 0.01         |
| <i>R-square</i>                               | 0.51  |                    | 0.00         |

These results allow us to validate the use of Azjen's model to predict the entrepreneurial intention of the students surveyed. We also note that the regression increases after the ETP, which could be interpreted as a refinements of student's attitudes and expectations as a result of the ETP.

### **Analysis of the impact of the ETP**

To test whether the ETP had an impact on students' intentions and attitudes, we used a mean comparison T-test and analyzed the correlation of the mean difference with other factors related to the students background.

As indicated in Table 1, there were limited differences observed as a result of the ETP when considering the entire sample. Among the three antecedents of the entrepreneurial intention, only the attitude related to perceived control was significantly influenced by the ETP (mean difference = 0.09,  $p < 0.05$ ) when considering the whole sample of students.

The two other measures of attitudes were not significantly affected by the ETP. However, there is a significant correlation between the impact (mean difference) of the attitude towards entrepreneurial behavior and intention and between the impact on the attitude related to subjective norms and the attitude related to perceived control (respectively 0.20 and 0.30,  $p < 0.01$ ).

When considering the entrepreneurial intention, the absolute impact of the ETP is not statistically significant (mean difference = 0.06,  $p < 0.36$ ). However the relative impact (mean difference divided by mean before the ETP) is significant (relative mean difference = 4%,  $p < 0.05$ ).

When considering all the respondents, the ETP appears therefore to have a significant impact only on attitudes related to perceived control and only, in relative terms, on entrepreneurial intention. Moreover, there are significant correlations between the impact observed, which might indicate a strong interdependence between how attitudes are affected by the ETPs.

Considering this apparent interdependence and the difference between absolute and relative effects, we have tested whether these results remain valid when considering only a subset of the respondents, taking into account their initial situation and backgrounds.

### **Analysis of students initial situations**

We first analyzed whether some student characteristics that are known to influence entrepreneurial behavior had an impact on the results presented above. To do so, we considered subsets of our sample based on the socio-demographic data we had collected and tested whether the results obtained on those sample differed from the results presented above (Table 3).

Table 3 Analysis of students background

|                               |             | Impact of ETP (mean difference) |          |       |         |           |
|-------------------------------|-------------|---------------------------------|----------|-------|---------|-----------|
| Sample                        | Sample size | Initial intention               | Behavior | Norms | Control | Intention |
| All students                  | 144         | 3.90                            | 0.00     | 0.02  | 0.09**  | 0.06      |
| Entrepreneurs in family = Y   | 90          | 4.05                            | -0.01    | -0.04 | 0.06    | 0.12      |
| Entrepreneurs in family = N   | 54          | 3.67                            | 0.00     | 0.02  | 0.15*   | -0.04     |
| Association experience = Y    | 78          | 4.09                            | -0.03    | 0.03  | 0.15    | 0.09      |
| Association experience = N    | 65          | 3.72                            | 0.02     | -0.07 | 0.01    | 0.03      |
| Foreign experience = Y        | 68          | 3.95                            | 0.00     | -0.04 | 0.09    | 0.07      |
| Foreign experience = N        | 76          | 3.87                            | -0.02    | 0.00  | 0.10    | 0.06      |
| Entrepreneurship training = Y | 33          | 4.28                            | -0.03    | -0.10 | -0.04   | 0.05      |
| Entrepreneurship training = N | 111         | 3.80                            | 0.00     | 0.00  | 0.13    | 0.07      |

\*  $p < 0.10$ , \*\*  $p < 0.05$

Using mean comparison T-test to compare the subsets considered above, the impact in terms of controllability appears to be somewhat higher for students that did not have any entrepreneurship training ( $p < 0.13$ ) or experience with an association ( $p < 0.14$ ). On the other hand, the presence of a role model, such as an entrepreneur in the family, appears to decrease the impact of the ETP in

terms of entrepreneurial intention, although not significantly from a statistical point of view. ( $p < 0.25$ ).

An international experience (more than six months spent abroad) had no impact on the influence of the ETP.

By comparing subsets of students with increasing initial levels of entrepreneurial intentions (Table 4), we tested whether the initial perspectives of the students about entrepreneurial intentions influenced the impact of the ETP,

Table 4 Analysis of students initial intention

|                 |             |                   | Impact of ETP (mean difference) |       |         |           |
|-----------------|-------------|-------------------|---------------------------------|-------|---------|-----------|
| Sample          | Sample size | Initial intention | Behavior                        | Norms | Control | Intention |
| All students    | 144         | 3.90              | 0.00                            | 0.02  | 0.09**  | 0.06      |
| First quartile  | 36          | 2.39              | 0.00                            | -0.08 | 0.11    | 0.25**    |
| Second quartile | 36          | 3.39              | 0.09                            | 0.05  | 0.19**  | 0.27*     |
| Third quartile  | 36          | 4.29              | -0.05                           | -0.01 | 0.03    | 0.09      |
| Fourth quartile | 36          | 5.56              | -0.07                           | -0.04 | 0.06    | -0.36***  |

\*  $p < 0.10$ , \*\*  $p < 0.05$ , \*\*\*  $p < 0.01$

These results indicate that the initial student perspectives on entrepreneurial intention does have a strong influence on the impact of the ETP, ranging from significantly negative to significantly positive. This calls for further research in terms of student selection and an equation of programs with specific students profiles.

In particular, initially identifying students for which the ETP will have no or a negative impact in terms of entrepreneurial intentions could be very valuable. While using a measure of intention as a

selection criteria might lead to biased results because of self-selection, using student background as criteria can provide potentially useful results, as there are significant differences in terms of initial intentions among the subsets of students considered (Table 3). In particular, students that have an entrepreneur in their family, with an experience in an association or having already followed an ETP, tended to have a higher initial entrepreneurial intention (mean differences equal respectively 0.39, 0.37 and 0.47, significance respectively of 0.08, 0.07 and 0.10).

#### **4. CONCLUSION**

In this research our main aim was to capture and understand variations in attitudes and intentions of students throughout a 3-day seminar focusing on entrepreneurship.

Looking at our results, and trying to extract from them key elements, we can identify a set of very interesting outcomes.

First, it seems that for the entire sample, the impact of the studied ETP on entrepreneurial intention is significantly correlated with perceived behavioral control. Other research has underlined this kind of relationship between intention and self-efficacy or perceived behavioral control. This could lead to further research aiming at testing relationships between perceived behavioral control and educational or pedagogical variables to understand the influence of such variables. These variables could concern, for example, pedagogical methods or types of trainers.

Secondly, taking into consideration subgroups of students selected from their initial proximity to entrepreneurship (coming from a family of entrepreneurs, having developed experiences involving entrepreneurial behaviors, having been exposed for a long time to international context), additional outcomes are evident. We found a positive impact of ETP on perceived behavioral control and on entrepreneurial intention for the following subgroups: students having not previously attended a course in entrepreneurship, students having not been exposed to

entrepreneurship through their family and students having not actively participated in the founding and the development of students associations. In the other cases we did not find an impact.

Third, in one of our most interesting results, we found that the impact of the ETP on entrepreneurial intention is significantly dependent on the student's perspective on entrepreneurial intention (see the table 4). This means that for students in the first quartile (those having the lowest level of entrepreneurial intention), the impact of the ETP is significantly positive and for the fourth quartile students (those having the highest level of entrepreneurial intention), the impact is significantly negative. In other words, the ETP could have some strong effects for some students, depending on their background and initial perspectives on entrepreneurial intention. At the same time, the ETP could actually decrease the level of entrepreneurial intention for other students.

These results lead us to ask some new and important research questions. For example, depending on the type of ETP, are there some ways and tools for selecting students and orientating them to the appropriate ETP for their profile and background? In some cases, ETPs aiming to give a first awareness to entrepreneurship are not useful (existence of counter effect) for certain types of students. Further research along these lines could improve our understanding about these issues. In addition, we are far from a good knowledge about the influence of the main factors playing a role within an ETP. Further research would allow us to verify specific relations between pedagogical and educational variables and perceived behavioral control. Consequently, our research model could be therefore improved by including new independent variables influencing one or more of Ajzen' antecedents.

**ABSTRACT**

This study fills a gap in previous research by performing an in-depth analysis of 146 entrepreneurship centers in the United States. This two part study looks at the characteristics of the entire sample of entrepreneurship centers and then examines the differences between top ranked centers versus non-ranked centers. The findings indicate that top ranked centers have three times as many endowed chairs as non-ranked centers. Top ranked centers also offer more comprehensive graduate programs. Overall, top ranked centers have more resources and manpower. The findings of this study will assist students, faculty, staff, administrators, directors and other stakeholders of entrepreneurship centers.

## INTRODUCTION

We investigated entrepreneurship centers throughout the United States. Utilizing a sample of entrepreneurship centers in the U.S., this study thoroughly examines two basic research questions to assist students, faculty, staff, administrators, directors and stakeholders to understand the characteristics of entrepreneurship centers. The first research question is: What are the determining factors of established entrepreneurship centers (e.g., faculty, students, courses offered, finances, etc.)? Focusing on the same factors, the second research question asks: What are the differences between ranked versus non-ranked entrepreneurship centers? The rankings for the top ranked programs were taken from the *U.S. News and World Report* over the last five years.

## LITERATURE REVIEW

Few researchers have focused specifically on aspects relating to entrepreneurship centers. In 1991, Sandberg and Gatewood examined research orientation, budgets size, and constituents for entrepreneurship centers. The most comprehensive study of entrepreneurship centers was entitled, "Successful Experiences of Entrepreneurship Center Directors" by Upton (1997). Funded by the Kauffman Foundation, Upton performed an in-depth case analysis on only nine entrepreneurship centers. Based on her findings she developed a best practices list for starting, directing, funding, managing, and marketing each center. Other than these two studies there is little knowledge to be gained from the literature regarding entrepreneurship centers. Given the lack of research in this area and the importance of entrepreneurship centers play to a university, we surveyed 146 entrepreneurship centers in the United States. To date this is the largest sample of centers ever examined in the literature.

## METHODOLOGY

### Sample and Procedures

The sample consists of 146 entrepreneurship centers located in the United States. The list of centers was obtained from the National Consortium of Entrepreneurship Centers membership, the St. Louis University website on entrepreneurship centers, the Babson College research lists, and an in-depth search of web sites from the Internet.

We received responses from 94 program directors for a response rate of 64%—13 from nationally ranked centers and 81 from unranked centers. The high response rate is probably due to the collegiality among center directors in the entrepreneurship field and the study was endorsed by the National Consortium of Entrepreneurship Centers (NCEC). For this study, we define an entrepreneurship center as having a Center for Entrepreneurship (which may use titles such as Free Enterprise, Family Business, or Innovation Center), academic curriculum in entrepreneurship (having three or more for-credit courses aimed at an undergraduate degree or graduate degree), external outreach activities, and faculty that perform research in the field of entrepreneurship. The study did not include Small Business Development Centers.

In this descriptive study, we break down our sample into three categories: (1) mean for the entire sample, (2) mean for top ranked centers and (3) mean for non-ranked centers. Utilizing t-tests and chi-square analysis we examined the differences between the top ranked centers versus the non-ranked centers.

For the purpose of this study, an entrepreneurship center is considered nationally (top) ranked if it appeared as a Top 25-program in *U.S. News and World Report* at either the undergraduate or graduate levels. The *U.S. News and World Report* rankings are based on responses from the Deans and Directors of MBA Programs at over 350 Accredited Schools of Business who rank the top entrepreneurship programs in the country. Based on their responses, a list of the Top 25 schools in entrepreneurship is developed by *U.S. News and World Report* at both the undergraduate and graduate levels.

## **RESULTS/DISCUSSION**

### **Center Characteristics**

Table 1 illustrates that the average age of all centers in the study was 8.3 years old. There was a significant difference between top ranked centers at 11.9 years old versus non-ranked centers at 7.7 years old ( $p < .02$ ). Ranked programs are, on average, 4.2 years older, which may serve as an advantage by having more time to garner resources, build curricula, legitimacy and brand name recognition that are needed to attain national status. When asked about the primary emphasis in the College of Business, the percentage breakdown for the entire sample was 74% academic programs, outreach 26%, and fundraising 6%. There were no significant differences between top ranked and non-ranked centers. This demonstrates the fact that the academic component drives these centers.

When asked about the percentage breakdown that universities place on teaching, research, and service, the average for the entire sample was 49%, 33% and 18% with no significant differences between top ranked versus non-ranked centers. This demonstrates that teaching and research (82%) comprise the majority of center's activities. Fifty-three percent of the founders in the sample were still working at their respective centers, however there were no significant differences between top ranked versus non-ranked centers.

The average student population for a school in the sample of centers was 16,578. Sixty-one percent of the centers were located within public universities. There were no significant differences between top ranked and non-ranked centers in regards to their classification (public versus private university).

The average number of students in an entrepreneurship program associated with a center was 173 (112 graduate and 61 undergraduate). Top ranked programs were significantly more likely to have a larger number of graduate students ( $p < .04$ ).

The bottom of Table 1 indicates where the Center for Entrepreneurship is located: Department of Management, Department of Marketing, Mixed within the College of

Business Administration (CBA), Independent Unit/Area (not a Department) and Independent Unit/Area (associated within a Department). Results for the sample indicate that centers were most often mixed within the College of Business Administration (CBA) (24 centers), an independent unit/area (not a department—22), an independent unit/area (associated with a department—19), Department of Management (16) and an independent department (8). The results show a center was significantly more likely to be ranked if it was an independent unit/area (associated with a department—6) at  $p < .01$ .

-----

### **Entrepreneurship Faculty and Staff**

Table 2 illustrates the differences in demographics among faculty in the study. The table shows that the average center had 5.4 faculty members teaching in the program (3.9 PhDs and 1.5 MBAs). The average number of tenure track and non tenure track faculty that teach is 3.0 and 2.2. The average number of adjunct faculty that teaches is 1.8 and the mean number of full-time and part-time entrepreneurship faculty that had started a business was 2.2 and 1.5. Each center had a mean of 2.8 and 1.3 full-time and part-time staff members. The average number of endowed chairs is one and the average amount of money that each position was endowed was \$982,041. An interesting finding is that 47% of the centers did not have an endowed chair.

Looking at individual differences between ranked and non-ranked centers we find that ranked programs fund more faculty positions in entrepreneurship. For example, ranked programs employed an average of 5.2 faculty members with doctorates while non-ranked centers employed 3.6. Even though this is not statistically significant, it demonstrates the serious commitment that universities with ranked centers place on resource allocation for entrepreneurship.

Ranked centers also reported 4.3 tenure track positions compared to 2.7 for non-ranked programs ( $p < .06$ ). The number of non-entrepreneurship tenure track faculty at top centers was also significantly higher than non-ranked centers, 3.2 versus 2.1.

Ranked centers also draw on the assistance of at more adjunct instructors 2.8 versus 1.7. The average full-time faculty member started 2.9 businesses versus 2.2 for non-ranked programs. The numbers are even more diverse when looking at adjunct faculty. Adjunct faculty at ranked centers started an average of 2.9 businesses while non-ranked adjuncts started 1.2 ( $p < .007$ ).

No significant differences exist between the employment of part-time and full-time staff members. Thus, daily duties and functions are perhaps equally met by both types of centers; however, in depth content delivery may be better in ranked centers due to the larger number of full time faculty. More full time faculty teaching in the concentration or the major better insures more topics covered, research undertaken, and collegial interaction in entrepreneurship areas—all factors that could partially account for higher national reputations.

-----  
Insert Table 2 about here  
-----

Another significant finding in the study focuses on the number of endowed chairs. The average center in the study had 1 endowed chair, with top centers averaging 2.31 versus non-ranked programs at .73 ( $p < .000$ ). On average, ranked centers had three times as many endowed chairs as non-ranked centers.

Table 2 also shows the average and median amount of money that is endowed to each of these positions. For the entire sample the average and median amounts of money that is endowed to each of these positions was \$982,041 and \$0 respectively. Significant differences were found between the ranked versus non-ranked centers for both average and median endowments for a chair. At top schools, the average was \$2,416,667 versus \$825,536 at non-ranked schools ( $p < .02$ ). The difference between the medians was \$1,750,000 versus \$0 ( $p < .00$ ).

### **Financial Operations within Centers for Entrepreneurship**

As illustrated in Table 3, the average size of a center's endowment for the full sample was \$3,891,304. The results show that ranked centers, on average, had \$10,409,500 more endowment money than non-ranked centers ( $p < .005$ ). This is also indicative of the non-ranked centers funding more their budgets from grants and contracts. An interesting side note is that 47% of the full sample had an endowment less than \$500,000.

The mean amount of scholarship money available to students for the full sample was \$25,731. Ranked centers had more scholarship money available, \$38,000 versus \$22,708. There was no scholarship money available for students at 17 centers. All respondents in the survey from top ranked centers had scholarship money available for students.

-----

### **Administration of an Entrepreneurship Center – Problems and Challenges**

An interesting aspect of the study was the inquiry into the major problems encountered by center directors in the administration of their programs. Table 4 outlines the various problems cited by the directors. It is important to make the distinction between those directors who started their center (founder) and those who were not the founder. We believe this distinction is necessary because certain problems are more inherent in the “founding” of a center versus those problems that arise afterwards.

For all of the centers in the study, the top five problems encountered for directors who started their program were time, funding, finding qualified faculty, legitimacy, and faculty jealousy. The major problems encountered for directors who did not start their program were funding, time, finding qualified faculty, and measures of success.

Among the ranked centers, the directors who founded their programs cited finding qualified faculty, funding, time, and legitimacy and as the most critical problems encountered. Those directors who did not start the center at a ranked school had the most problems with time, finding qualified faculty, the administration, and obsession with rankings.

Directors who started a center at non-ranked centers most pressing problems were time, funding, legitimacy, finding qualified faculty, and faculty jealousy. Directors who did not start the program at non-ranked centers programs cited funding, time, finding qualified faculty, legitimacy, recruiting students, and measures of success as the most pressing problems.

Two significant differences were found in each category of director. Founding directors from top ranked centers had significantly more problems in finding qualified faculty ( $p < .01$ ). Founding directors from non ranked centers had significantly more problems recruiting students ( $p < .047$ ). Non founding directors had significantly more problems in obtaining funding ( $p < .005$ ) and legitimacy ( $p < .01$ ).

-----  
Insert Table 4 about here  
-----

### **Perceived Measures of Success**

The directors were surveyed about their perceptions of how the faculty and administrators measured the success of their entrepreneurship centers. The results are reported in Table 5.

For the entire sample of centers, the directors' perceptions of the faculty's top measures of success for a center are (in order of importance): (1) number of students in the program, (2) student evaluations, (3) number of graduates and (4) funding generated. The directors' perceptions of the administration's top measures of success for a center are: (1) number of students in the program, (2) recognition, (3) funding generated and (4) number of graduates.

For top ranked centers, the directors' perceptions of the faculty's top measures of success for a center are: (1) student evaluations, (2) recognition, (3) number of graduates and (4) number of students in the program and (5) research. The directors' perceptions of the administration's top measures of success for a top ranked center are: (1) recognition, (2) number of students in the program, (3) number of graduates and (4) student evaluations.

For non ranked centers, the directors' perceptions of the faculty's top measures of success for a center are: (1) number of students in the program, (2) student evaluations, (3) number of graduates and (4) funding generated. The directors' perceptions of the administration's top measures of success for a non ranked center are: (1) number of students in the program, (2) recognition, (3) funding generated and (4) student evaluations.

Two significant differences were found in the results. In the category, "directors' perception of faculty measures of success", non ranked centers ranked funding generated as a significantly more important measure of success than ranked centers ( $p < .04$ ). In the category, "directors' perception of administrators' measure of success", external programs was a significantly more important measure of success for non ranked centers ( $p < .01$ ). While not significant at the .05 level, recognition was moderately significant ( $p < .07$ ) for directors' perception of faculty measures of success. Recognition was more important to ranked schools than non ranked schools.

## **CONCLUSION & IMPLICATIONS**

This study fills a gap in entrepreneurship education research by surveying the largest sample of entrepreneurship centers in the U.S. ever attempted and obtaining in-depth information about the characteristics of these centers. This descriptive study breaks down the sample into three categories: the entire sample of entrepreneurship centers, top ranked centers and non-ranked centers.

C. Thomas Worley, Director at the OSU South Centers

Emmanuel Mbiha, Professor, Sokoine University of Agriculture (SUA), Department of Agricultural Economics and Agribusiness

**ABSTRACT**

The African business environment is changing dramatically as a consequence of liberalization policies and exposure to free international flows of capital, services, and commodities (Kristiansen, 2002). The small-scale enterprise sector is an important driving force for economic development in Africa (Mead & Liedholm, 1998). The purpose of this paper is to identify obstacles and interests of agribusinesses in Tanzania, which is located on the eastern coast of the African continent. Agriculture is the foundation of the Tanzanian economy, yet there is limited research on entrepreneurship and agribusiness in sub-Saharan Africa. To advance Tanzanian economic development through entrepreneurship in agriculture, the Ohio State University (OSU) and Sokoine University of Agriculture (SUA) joined forces. With financing from USAID's Association Liaison Office (ALO), OSU and SUA surveyed 61 firms in 7 administrative regions in mainland Tanzania. Africa's challenges are numerous and complex, but there is also much potential and opportunity for growth and development. Together, OSU and SUA are addressing challenges and opportunities, building institutional capacities through linkages with the private sector, and developing an agribusiness management program at SUA. They are advancing entrepreneurship education and continuing to collaborate with stakeholders in the development of personal, institutional, and environmental factors for promoting entrepreneurship in a transitioning economy. It can be concluded from the findings of this survey, that there is demand for training on business planning, market management and other priorities. It can also be concluded that agribusinesses are willing to participate in a new Agribusiness Management Program (AMP) at SUA.

# **HIGH-TECH VENTURE START-UP BY CIVIL SERVANT RESEARCHERS: THE MANAGEMENT OF THE COUPLING-DECOUPLING QUESTION**

## Abstract:

If many works concern exchanges between scientific and industrial communities, the French case shows an original situation with the Act of July 1999. French researchers working in public laboratories are also civil servants and most of the time not concerned by entrepreneurship question. The Act gives them authorisation to set up their own venture. The path used by researchers to become entrepreneur is full of questions. We will analyse this situation according to two theories: first the theory of social networks and second the orders of worth. These theories will help us to highlight the situation of researchers embedded between public and private stakeholders, and how the decoupling process could be managed by the researchers.

## Introduction:

The technology transfer of university research findings towards high-tech venture is the subject of numerous works, for example: the international study of Pirnay on the university spinoffs (2001, 2002) or the work of Shane about academic entrepreneurship (Shane, 2004). In France, since the end of the ninety's, high tech venture is in the heart of research and innovation public policies (Mustar and Penan, 2003). According to this logic, the Act of July 12th, 1999 focuses on university spinoffs as a way to transfer technology research, targeting researchers who are civil servants, even if most of them are not really attracted by this opportunity (Emin, 2003). A report on public incubators reveals, however, that nearly a hundred civil servant researchers used the 1999's Act. It demonstrates that the law answers a real demand from researchers. However, it does not explain how they use what is supplied by the law. This type of entrepreneurship concerns would-be entrepreneurs who work as civil servant researchers<sup>1</sup>, who are remove from the business community, and sometimes rebel against imperatives of the market. Moreover, their status forbids them to have another job. Now, the law of 1999, easing some the constraints: it authorizes the researchers to go out gradually from the public area to join the market world. How do they consider this passage? Which obstacles do they have to overcome? With what kind of aids? Are their own establishments and the incubators sufficient supports? What about the relations with stakeholders? Answers to these questions helps to understand the specific process of university spinoff by civil servant researcher.

---

<sup>1</sup> In France, faculty and research staff are national civil servants and are divided in two categories: the first one works for the university, the second one works for specialised establishment such as CNRS, INSERM, INRA...

To consider this problem, we will use the theory of the social networks and the concept of embeddedness (Granovetter, 1985). The civil servant researcher has to go out of his initial networks and tie up links with actors in a trade perspective, what Granovetter calls the coupling-decoupling process. Therefore, we will combine this theory with the concept of orders of worth developed by Boltanski and Thévenot (1991, 1999) to understand the question of coordination among stakeholders.

The theoretical framework, combining the social networks theory and the concept of orders of worth allows to complete entrepreneurship theory on the university spinoffs. Our analysis is based on the study of seven projects of high-tech ventures. Results underline that the researcher lives, from the beginning, in an ambiguous embeddedness, followed by a partial decoupling from the non-profit area, even if tensions between various stakeholders require him to adopt a trade logic very early.

We shall present in the first section the theoretical frame of the analysis. The second section will clarify the Act of 1999 and the empirical study. Finally, the third section will expose obtained results.

## **THE THEORETICAL FRAMEWORK: A COMBINATION OF SOCIAL NETWORK THEORY AND ORDERS OF WORTH CONCEPT**

If literature in entrepreneurship allows understanding the spinoff process, the specificity of French case (the researcher's status) supposes to build a special theoretical framework to be understood. This one is based on social networks theory and completed with orders of worth concept.

### **University Spinoffs: Contributions of Social Networks Theory**

Literature in entrepreneurship operates on a distinction between pure creation and spinoff (Pirnay, 2001, 2002). The spinoff phenomenon corresponds to the creation of a company from an organization. The difference between push spinoffs and pull spinoffs underlines the importance of the context of the creation. Thus, a push spinoff has the explicit support of the organization. This is the case in the university spinoffs. Academic studies on this subject contribute to understand the process in which the researcher is at first a would-be entrepreneur.

The question of the process, central in entrepreneurship (Gartner and alii, 1992; Shane, 2004), can be enriched by the social networks theory. Many researches insist on the role of networks in the entrepreneurship process (Hoang and Antoncic, 2003). For the social networks theorists (Burt, 1992, 2000; Granovetter, 1985), companies are built by individuals whose action is at the same time facilitated and limited by the structure and the available resources of the social networks where they take place. The embeddedness gives confidence and resources to the entrepreneur (Granovetter, 1995). But the situation is paradoxical (Uzzi, 1997) because it could be considered in the same time as a constraint. Insertion in an interpersonal relations network could make the company dependent to his network such as satisfied some demands of its members, bad for the profitability of his project. Granovetter illustrates this danger through the example of the Chinese entrepreneurs (1995, p.142). To limit links with the domestic and friendly environment, the Chinese entrepreneur spends most of the time in his native region. The balance between "coupling" and "decoupling" constitutes the condition of its development. The process of decoupling followed by the entrepreneur is presented as necessary for his survival. The entrepreneur has to go outside (at least partially) of his initial network so that his entrepreneurial

project succeeds. It allows him to escape some of the non economic obligations which are demanded by the network into which he was inserted initially. Nevertheless, this decoupling is relative in itself, because it does not imply a total break with the initial network which has supplied useful resources for the launch of the project.

As underlined by Chabaud and al. (2003), the question of coupling-decoupling can become richer with the notion of structural hole developed by Burt (1992). The entrepreneur is located in the intersection of networks which have no (or few) links. Thus, he is able to add value by being go-between to various networks and building bridges between the various structural holes. Someone living at the intersection of two social worlds has more of a chance to have good ideas (Burt, 2000) and to be in a good position to innovate. For Hite and Hesterly (2001), it is towards this type of more «calculative» networks, i.e. characterized by economic relations and less socially embedded, that the creator has to turn. Jack and Anderson (2002) demonstrated how entrepreneurs recognize and treat some aspects of their social structure in order to exploit some of its opportunities.

The theory of the social networks, following the example of the literature in entrepreneurship, is interesting in regard to the process which one follows when he decides to set up a company. Moreover, it underlines the interest to lean on a network of relations, then to go out of it, to treat the various networks, to link them. However, in the very particular case of a university spinoff set up by a civil servant researcher, this theoretical frame is not sufficient to understand consequences of his new status. This change widely explains difficulties, conflicts, ambiguities met during the spinoff process as the researcher goes from a non-profit environment to a trade one. The orders of worth concept allows a better understanding of this process by explaining the specificity of framework in which researcher is or will be during the process, their different logics of action and the potential conflicts.

### **The Concept of Order of Worth**

According to the approach developed by Boltanski and Thévenot (1991, 1999), many situation in social life can be analysed by their requirement for the justification of action. The logic of action appears with the meeting of an actor and an action characterised by a historic and institutional context, symbolic and mythical references, structural constraints. Since a plurality of mutually incompatible modes of justification exists, disputes can be understood as disagreements either about whether the accepted rule of justification has not been violated or about which mode of justification to apply at all. The article develops a grammar of such modes of justification called orders of worth (*grandeur*). The actor does not exist in itself, independently of the situation in which he has to face. These situations of action are very numerous. In *De la justification* (1991), the authors focus on six worlds. In each of these, coherences are mobilized around persons, objects, representations, and relational designs which are so many faces allowing to recognize from which nature is the situation, as well on a person included in one of these worlds as on an observer point of view which tries to understand it. In each world, people value “states” and, in case of controversy, they agree in reference to a common superior principle. Disputes can appear among people belonging to two different worlds and “quarrel” (the confrontation of two worlds) finds a solution either in the exclusive reference to one of the two worlds, or in a local agreement (a temporary and not generalized deal between people staying in their world), or in a compromise (an agreement which exceeds the two worlds, stable because it builds with objects resulting from each of worlds). Thus, the concept of orders of worth not only demonstrates the way agreements

between people are built and realized, but also the coordination among people who work according to various.

The spinoff process by a civil servant's researcher implies two different situations of action, each of those having specific legal rules and different objectives. Indeed, the civil servant researcher evolves in a professional environment that we shall call the public or non-profit area, characterized by particular legal rules (the status of Public service, its rights and its obligations), within which the notions of public utility, the general interest is advanced. The entrepreneur evolves in a private area governed by his own legal rules, economic aims and mostly by the search for individual interest and for profit.

The specificities of these two areas are similar to two of the worlds described by Boltanski and Thévenot. The first one, called civic world, is defined through “greatnesses” such as the superiority of the collective interest, the embodiment of a general interest, the importance of the equality. The second, called market world, is described by the notions of competition, opportunism, profit. And among the two, exist “an inflexible opposition between public good and private interests” because “the definition of the public utilities is built on the critical opposition towards a definition of a trade service” (Boltanski and Thévenot, 1991 , p. 318-319).

The authors clarify, furthermore “that the same people are able to take into account many kinds of “greatnesses”, which is different from the hypothesis that links value systems or cultures to members of the same social group or the same institution” (ibidem, p. 189). Nevertheless, considering the strong specificities of each area of our cases, it seems possible to identify two archetypes of action: one corresponds to the civic world and the other to the market world.

Using the theoretical framework of the orders of worth underlines differences between stakeholders’ ways of coordination because the use of the 1999 Act lead the researcher from the non-profit area to the commercially oriented one. Embedded professionally in the first one of which he uses a whole set of resources, he escapes it by the game of the Act and of his own objective –to set up a company-. The path to the other area can be compared to a “decoupling” of the researcher. Then, he will face the market world with its proper logics. The “decoupling” implies a change about regulation and conflicts resolution among people, what does not indicate the theory of the social networks. By the use of the Act, the researcher remains in a structural hole (Burt, 1992). Even though universities and companies develop several types of collaborations (Shane, 2002), each remains centred on his own activities and links, and relations remain weak, especially in France. Will the researcher succeed in establishing bridges between these two areas, in facing “situations found in the different worlds, to know how to recognize them and be able to adapt himself (Boltanski and Thévenot, 1991 , p. 266)?”

To understand the mechanics in this kind of a spinoff and try to address the questions, it is necessary to put it through the context.

## **THE CONTEXTUALIZATION OF THE DECOUPLING AND THE EMPIRICAL STUDY**

The coupling-decoupling process studied here is strongly dependent on the very particular context set up by the Act of 1999. This Act about innovation will be clarified. Then we shall present the methodology used to lead empirical study.

### **The Contextualization and the Act about Innovation**

The French Act about innovation breaks the principle of the suspension for a civil servant to create a company. This exception is limited to the technology transfer of his research works. So, the object of the future company is defined in a restrictive way. The establishment (University, School, Establishment of research) where the researcher formerly worked must give an agreement and verify that this condition is effectively followed. The researcher will then benefit from a temporary status. Expressed in the article 25-1, it allows him to start a company while keeping the possibility, if he wishes, to go back to his first job. He has the choice between a “détachement”<sup>2</sup> or “mise à disposition”<sup>3</sup>.

The agreement given by the establishment is available for two years, renewable twice. Also, he must obtain a second agreement given by the Commission of deontology. This one looks at the possible incompatibilities between his researcher’s mission and his project, and must be informed about all the major evolutions of relationship between the company, the researcher and the establishment from which he comes.

At the end of this period, the entrepreneur can ask for a “mise en disponibilité”<sup>4</sup> (he is not civil servant any more), a dismissal or a reinstatement.

Relations with his establishment are not reduced to this agreement; it includes another very important contractual dimension. The entrepreneur will be able to use his research, but it owns to his establishment (university for example). That’s why an agreement will define exploitable works by the future company, as well as rights and obligations of the two parts of the relationship. During this contractual phase, are detailed financial modalities linking the two parts: 1. royalties due to the university or the School and 2. the possible coverage (temporary) of the entrepreneur’s salary if he uses the “mise à disposition” or “délégation”..

## **Empirical Study**

The aim of our work is to confirm by the theory the phenomenon of decoupling means of data collected for a previous study. These were already restored under the shape of an “intrinsic” case study according to Stake (1994), that means not having a theoretical validation. To reach it, the data must be converting in an “instrumental” case. From then on, case plays a role of support in the theoretical construction, facilitates the understanding of the phenomenon and advances reflections and perspectives of search. Confrontation with the theory allows the case to reach the external validity such as describes by Yin (1989).

Our empirical study aggregates several sorts of data allowing consideration of context and process. It was realized in two ways: In the first, Act, institutional environment, situation and role of the actors were studied from texts. The Second step, centred on the process of decoupling and its consequences for the researcher who wishes to create its company, was compiled on the basis of interviews.

In the first stage, Act itself, decrees and circulars relating to it were consulted as well as the various texts treating the status of public service and some of civil servants researchers. We also examined the speech of the Minister presenting the project to the Assemblée National<sup>5</sup>. This

---

<sup>2</sup> Détachement : The civil servant keeps the advantage of is status (more particularly the rights for pension) and is allowed to go back to his previous function after 6 years. He is paid by the spinoff.

<sup>3</sup> Mise à disposition : The civil servant keeps the advantage of is status (more particularly the rights for pension) and is allowed to go back to his previous function after 6 years. He is paid by the university.

<sup>4</sup> Mise en disponibilité :The civil servant doesn’t keep the advantage of his status, excepted the opportunity to go back to his previous function after 6 years.

<sup>5</sup> French Parliament

documentary collection included studying the legal subtleties which the entrepreneur has to face. Additionally, the first stage contained an institutional dimension. The number of public actors implied with the implementation of the Act exceeds what exists usually within the framework of assistants to start-up. At this point, the question was to identify and to select people concerned with entrepreneurial venture as a tool of technology transfer, to understand their role, and then to proceed to interviews.

The Second stage concerned essentially the analysis of interviews framed with two different set of questions, one for institutions interested by the spinoff project, the other for the researchers-would-be entrepreneur. Conversations lasted one to two hours some of the concerned people having been interviewed repeatedly between 2001 and 2003.

The first set of questions was administered to fourteen people within eight institutions. It was structured by the following subjects: the role of the institution in the spinoff process engaged by researchers, the material and relational elements set up since the Act, and their attitude about the spinoff led by a researcher.

The second set of questions was administered to seven would-be entrepreneurs (cf. table of cases, appendix 1) from two French counties (Lille and Lyon). This set included five dimensions: the legal status of the company or the future company, the statutory choice of the entrepreneur, the relations with the establishment, the relationship with the other actors, especially investors, and the perception of the Act by the interrogated people.

Interviews were then coded by subject as the unit of analysis tackled issues by the interlocutors, their place in the speech and so the importance of these. So the coding was realized after. These subjects were also put in perspective with regard to the context, but also some toward the others. By revealing the importance of certain subjects in speeches, the analysis of contents suggests explanations of the behaviour of the people interviewed. These explanations, then, allow us to understand how the researchers manage their decoupling from the non-profit area.

## **THE COUPLING-DECOUPLING QUESTION MANAGED BY THE RESEARCHER**

The majority of the interrogated researchers assert that they would not have left their positions without the Act. It globally strengthened a certain number of situations by adding financial and fiscal supports for the benefit of entrepreneurial venture, thereby facilitating the entry to incubators or nurseries, enabling the young company to work with various networks. (Chabaud and al., 2003). It also helps researchers to start new companies and to commercialize university inventions, new mission led in parallel with the classic one of technology transfer, and by giving a legal frame to practices which would have been illegal. However, by using the Act, the researcher is in a problematic situation. If the original coupling in the non-profit area is maintained by the use of the Act, it is at the same time ambiguous: the decoupling remains relative. This process is differently administered by the researchers. The theoretical frame of the orders of worth reveals that some of them stayed in the civic world while the others went over to the market world.

### **An Ambiguous Original Coupling, but a Relative Decoupling**

The ambiguity of the original coupling shows through in three types of relations which the researcher maintains. Relations with on one hand the members of his laboratory, on the other hand the persons in charge of the implementation of the Act who are also responsible for technology transfer office, and finally the private investors whom he needs to develop his project.

Nevertheless, this ambiguity of the previous coupling does not lead to a total break with the non-profit area. Different links are maintained with it and give some proofs of a relative decoupling.

### An Ambiguous Embeddedness

Being a would-be entrepreneur, the researcher meets incomprehension, even distrust, from members of his laboratory: “Many people of my laboratory thought that it was not my profession to create a company”(case 1). “There was a definite hostility. Everything was made to block my project, a part of the lab was very hostile. Some thought that I pirated public service. It is rather hallucinating this French mentality” (case 3). “With regard to the search team, they had the impression that we wanted to make money with them... [ establishment of membership of the concerned researcher]; I left of this team” (case 4). Some conceive with difficulty that a researcher can become an entrepreneur and that he takes advantage materially and financially of works produced unselfishly by a team. There is a certain tension in working relations, strengthened when the would-be entrepreneur convinces some of his co-workers to follow him in the adventure (case 3 and 4). This incomprehension is strengthened by the ambiguity of their professional situation during the process of creation. Several researchers felt this embarrassment. “The difficulty is to be still in the organization chart and to defend the interests of the venture. We have a double role: with regard to the research team and with regard to the new business start-up” (case 4). “At the beginning, we were representing school. We overlapped because we also represented the venture” (case 3). On the road to becoming an entrepreneur, the researcher meets people from the technology transfer office within his establishment, entering another type of ambiguity. They are supposed to be competent to inform him about the Act, but they often suffer from a lack of mastery of his interlocutors. They are supposed to be the only ones in the establishment who know and implement the Act. “At the Beginning of 2001, I met the human resources manager and she said to me “your file did not leave” she did not know the new Act” (case 7). “The university was contacted [in October, 2001], but no reaction [in June, 2002], while we had made propositions” (case 6). “In the choice of status, we managed by ourselves, the [establishment] had no knowledge ... We waited for Act for quite a lot of time; we had met people who prepared it... we gave information to them [establishment]” (case 3). “There are unresolved questions at every level; participation in the capital for example, 15 % with or without the family? We received a vague answer, either yes or no (case 3). “We do not know if I can get a complement of salary, I hope because my grant is going to be killed” (case 5). This lack of mastery of the Act contrasts with the expertise in negotiation on rights and obligations relative to the exploitation of the transferred research. The conclusion of the agreement in which they are clarified reveals not only a legal reality which the researcher barely understood, but especially tensions which he did not suspect. “Negotiation about royalties was tightened... To defend my interests, I did not rely on my establishment” (case 1). “Negotiation was hard for consultancy’s contract between the School and the company” (case 2). “At the beginning, the [establishment] wanted 25 % in the capital of the company. We negotiated more than 18 months to have a license of our own works. My status is the “détachement”<sup>6</sup> from the [establishment] but it continues to pay me over the first 6 months, I do not pay off. We asked to continue that way during 2 years but I have no news since the end of May (6 months)”. “The [establishment] agrees but if I sign agreement on the license. It is tit for tat” (case 4). “The negotiation of royalties is one of the most important stages before starting a new company. Three

---

<sup>6</sup> Détachement: see note n°2.

months of negotiation even if the transfer technology office is experienced in this domain” (case 2). “The licensing agreement is always in negotiation. Royalties go between 3 and 5 % of the turnover; it is huge because we still have many technical problems to solve before the production and the marketing step, what still supposes important investments. I have no experience in negotiating royalties, and no one will help me. The university tries to protect its interests, but I still belong to the university” (case 5).

Even though the researcher believes that his project belongs to his establishment as well (“it is the start-up of the university” (case 5), he discovers not only that he is going to have to pay for the right to use his research, but also another side of its establishment. The university is supposed to assist him with the project, but he must also negotiate the modalities of such exploitation. Thus, the public establishment looks at the same time for a return on realized investments and for sources of financing for its missions. This last objective appears implicitly in the Act of 1999 with the implementation of the SAIC (services of industrial and commercial activities), which allows the public establishments concerned to have a clear reading of all his activities and so to develop them more. Besides the direct return on investment, establishments also expect indirect consequences (recognition, fame). Such objectives give them a rather ambiguous role: they support the project of their researchers, advise it (with an often insufficient mastery of the Act), but in return wait for consequences which surprise the researcher and often appear as a supplementary constraint for the project.

Finally, in relations with the private investors (when one exists) one suspects that they do not appreciate the situation of the researchers who are still in the public area and not totally involved in their company. “The financiers do not like it; they would wish they are 100 % inside [i.e. means outside the frame of the Act]. The participation of the School in the capital, they can’t stand it... They are afraid that we are subsidized venture” (case 3). “The investors require that I am completely in the company. This total implication would indicate that the entrepreneur trusts his company” (case 2).

The “moving” status is perceived by these stakeholders as the expression of a lesser implication of the entrepreneur. How then to obtain his partner’s trust if he doesn’t seem to believe in his company? In a more general way, the subsidized character gives to the company is most of the time a bad point for it. So, the participations of universities or the other establishments in the capital of companies are considered unwanted, so as to reduce them to some insignificant percentages (notably in terms of control!): 5 % in the case 1 “not to frighten the investors” while the establishment wished between 20 and 25 %; 25 % in the case 3 but with a clause of exit in five years; nothing in the case 4 while the establishment wished 25 % of the capital.

In spite of the ambiguous of the original embeddedness found in many case, the process of decoupling remains relative.

### A Relative Decoupling

Links with the laboratory of the researcher are maintained in various ways: by the association, by get round the Act and by the agreement of cooperation.

-By the association. The would-be entrepreneur collaborates with the other researchers of the laboratory who lend their scientific help. This participation is made within the framework of the art. 25-2 of Act: the concerned researchers do not leave either their civil servant's status or their position within their institution and so within their laboratory. “We thought we were in the same situation and made everything together, but it is not possible because the idea is to

maintain a bridge between the company and the School” (case 3). “It is necessary to keep a link with the laboratory” (case 4). “We have other projects with the university” (case 5).

-By get round the Act. Art. 25-2 proposes a statutory organization not foreseen for spinoff and which forbids the researcher to exercise the functions of a leader and to possess more than a certain percentage in the capital of the company. It was, however, used with the agreement between the establishment of the researcher and the Deontology Commission: “We mentioned explicitly that my wife was at  $x$  level in the capital and my father at  $y$  level (case 3)”. Only one researcher involved in the project of case 2 declares him: “I am scientific consultant. I would have been able to ask for the 25-1, but I did not choose it for two reasons: professionally, I am responsible for a team and personally if I left in “détachement”, the level of wages would be the same. My wage as a professor is about the same as an engineer ... They proposed that I have a place in the board « (case 2).

-By the agreement of cooperation. It is about royalties, and also transfer of the other studies led with the laboratory, or the possible scientific collaborations. Case 5 is significant on this point: “The idea is to create a start-up able to do continuous technology transfer. We work on the long term. There will be several types of projects: to market the technology, to finance the university’s research or to simply subcontract”. Case 3 is based on exchange of services between the spinoff and the laboratory: “All developments made [by the spinoff] are in relation with the laboratory”.

The separation between the spinoff and the laboratory does not mean a total break. To maintain the links is the best way to help the development of the project. Maintaining the relation provides an evident benefit to the spinoff: its core is based on innovation; it has to keep in touch with the elements which will feed its growth. This is also why the article 25-2 presents an obvious interest because it allows the researcher to become an entrepreneur and the entrepreneur to remain a researcher.

The process of decoupling, as illustrated in the interviews, places the researcher in front of a whole series of difficulties: ambiguity of its interlocutors, ambiguity of the situation, tensions, and sometimes conflicts due to the researcher's status. The theoretical frame of the orders of worth gives elements to understand and interpret these stakes.

### **The Management of the Decoupling Highlighted by the Orders of Worth**

This concept gives an interesting clarification of the various types of tensions. As we analyzed these cases, the would-be entrepreneurs were subdivided into two groups: those that continued to be in a non-profit logic and those closer to the trade logic.

#### **The Preservation of a Strong Non-Profit Logic**

The researcher is embedded in a professional sphere (the laboratory, his colleagues) characterised by the non-profit system. They do adhere to their value system. The desire to create a company is not understood; it is even perceived as opposite to the public service, and against general interest. In one of the cases, the researcher resolves this type of tension by using a common superior principle specific to the civic world: “In my case, people understand. I have a good commercial contact, I can speak to political people, to journalists, so I can have a spinoff which will be the pride of the university. I leave a mission with the spinoff and then I go back to my establishment” (case 5). Few tensions exist here and they relate to the common superior principle of the community: every stakeholder works for it. On the other hand, in another case (case 4), the

researcher is in conflict with his establishment: continuing to take place in a non-profit area based on collective. He does not understand that his establishment does not give him all the means which he demands. The relation with the laboratory is strongly compromised: "I lost my power on the team, and at the same time no one takes over my job so that not easy for the laboratory". At the same time, his relations with the university technology transfer office are tightened. The researcher said: "They want to transfer but they are not sure what it is ... They are not efficient in the search for venture-capital... I asked for a research engineer, I got no answer, not even a negative one!". In case 4, the would-be entrepreneur remains in the non-profit field. He asks his establishment to get resources to achieve his project without any regard to their cost. That raises obvious tensions. The establishment has a cost versus profit approach of the technology transfer. They want gain on the investments they have made. Quarrels (conflicts between two worlds) are explained by the reference to each one exclusively to his own world, which does not help the development of the project

In these two cases, the private investors are not still present. In the case 4 however, they are integrated by giving funds to establishment: aside from royalties, they will have to pay cash to participate in the project (This entrance fee decided without their input shows a lack of consideration of the market world by the researcher). How can investors agree with a fee they did not negotiate?

Finally, in these two cases, the projects are still at the very beginning, which could explain why the researcher remain in the same "world" in the sense of the orders of worth.

### The Entrance to the Market World

The other would-be entrepreneurs who had a more developed project, became aware that they will have to change of "world". If their relations with the laboratory are strained similar to a quarrel, there are specific resolutions. Case 2 uses a "local classification" (temporary and not spreadable) with the choice of the 25-2 to spinoff: "In the Act, there are absurd constraints, and it was necessary to find parallel solutions". Others managed to establish a compromise between the two "world" with resolutions to each problem. Case 3 illustrates it well: "There was a search for balance. If two contracts concern software packages, the first one transfers the totality of the property to the company but with a right of free use for the laboratory. The other one grants an exclusive distribution but with an obligation to integrate developments realized with the laboratory and a right of free use of developments realized by the company for the benefit of the laboratory".

In relations with the university transfer technology office, the researchers understood that their establishment followed interests which did not always fit with their project. They were often aided by specialists in industrial property who were well-informed about legal questions on technology transfer. They knew how to sell licenses and patents at the best price. A significant example of this approach is in case 3 where every stakeholder of the negotiation agreed to be represented by lawyers (objects of the trade world) who act as referees taking into account the best interests of each. The presence of the researcher in the trade world to finalize the negotiation does not alleviate all the tensions, but it allows him to use examples of the trade logic and to solve controversies through the use of a common principle (e.g. the maximisation of the interests of each), with cases of the same nature (e.g. lawyers).

This appropriation of objects and logics of the trade world is made during the process of decoupling: the negotiation of rights about transferred research and contacts with actors of the private area, such as the lawyers, the management consultants, etc. set off this mechanism. In this

respect, entrepreneurs who follow courses in management were helped: “Following management courses helps to recognize the company’s problems” (case 1); “It is a guide” (case 3). This learning is important because the researcher is totally dependent on his references in the non-profit area. It gives him, more than a consciousness, a knowledge of another world in the sense of the orders of worth.

Moreover, relations with private investors participate in this evolution in the sense that entrepreneurs are not satisfied with their position in the civic world and ask for a real involvement in the market one. Any element which does not correspond to their world, represents for the investors an incompatible risk to the success of the project. That is why some researchers want to leave the Act before their time. “The investors require that I am completely in the company (case 3); it is the proof of my involvement (case 2)”. Being in relation with the market world seems to hasten the decoupling of the researcher.

## **Conclusion**

The theoretical framework, combining the social networks theory and the concept of orders of worth completes the entrepreneurship theory on the university spinoffs.

The results of our research show the specificity and complexity of the process of spinoff followed by the researcher, and can be abstracted in three points:

- On one hand, they clarify the notion of decoupling by explaining the nature of the link maintained with the civic world and the rise of new coordination systems that the entrepreneur has to articulate. He does not go from (Hite and Hesterly, 2001) a “cohesive” network to a more “calculative” network in the phase of development, but he changes his references. Legally, economically, statutorily, he develops other relations with the stakeholders of civic world.
  - On the other hand, they highlight the concept of structural hole. The researcher does not develop a strategy to position himself in the interface of independent networks. The Act places him that way: there is no intention in that case. At first, the researcher, if he wants to make a success of the project, has to connect the civic world and the trade one. It is more a necessity than an opportunity. Intermediation is not a wanted role, but a compulsory one. Also, this process is rather binding, if not delicate ... The concept of structural hole often presented as an advantage to be looked for by the entrepreneur is here more a source of embarrassment.
  - Finally, the results underline statutory contingency of the decoupling. This must be understood in a contextual way. The particular status of Public Service, implementation of the Act about technology transfer research, is a given element of the context of the decoupling.
- Naturally, our work calls for other research. We have at least two directions. The first should deepen investigate the reality of the structural holes in which the researcher is placed and estimate precisely the constraints and opportunities which he meets. A study more focused on the private stakeholders and their relationships with entrepreneurs could investigate the role played by maintaining links with certain actors or institutions from the public area for the profit of its relations with those of the private one. A second track of research should lead to an international comparison to identify the differences of context and impacts on the process of decoupling.

### **ABSTRACT**

The development of a highly competitive, technology-based information society in the United States has caused an increased need for attracting and retaining skilled workers in small and medium enterprises. The very nature of business today requires these firms to compete on a global basis with, in some cases, less knowledgeable and skilled employees than larger firms. Success depends on such firms being able to produce a comparable product or service at a lower cost than competitors. Thus, small and medium enterprises often seek to use their human resources to create a competitive advantage. Employee training and development is one means to this end.

The purpose of this paper is fourfold. First, it provides a brief overview of why training and development is important in today's environment, paying particular attention to why employers do not train their employees as well as why they do. Second, the paper summarizes what the leading authorities say regarding employee training and development. Third, it reports the initial results of a pilot study of small and medium enterprises in West Texas in order to ascertain what types of training and development these owners and managers believe their employees need, what types of training methods are already in place for employees, and what types of training and development are needed by owners and managers. Ultimately, the paper concludes with a discussion of what this all means for small and medium enterprises.

### **INTRODUCTION**

Lack of skilled human resources as well as employee training and development has been blamed for American companies losing market share in the global marketplace (Lichtenstein, 1992; Senge, 1994; Cross & Funk, 1997; Yochelson, 2000; Carnevale, 2005). A growing illiteracy problem is also impacting employers' ability to find adequate workers. A survey conducted by the National Association of Manufacturers found that 60 percent of new jobs will require more than a high school diploma but 70 percent of new workers will not have it. Companies surveyed also stated that inadequately educated workers made it difficult to upgrade technology (Anonymous, 1992). Another study conducted by the United States government found that approximately 90 million adults do not have the literacy skills necessary to write a simple letter

(Anonymous, 1993). But, these studies were reported more than a decade ago. Hasn't this changed?

Interestingly, eight years later, *Winning the Skills Race*, a report issued by the Council on Competitiveness, concluded that there is an acute skills shortage in every part of the country that threatens the very foundation of American competitiveness (Yochelson, 2000). Additionally, a National Federation of Independent Business Small Business Poll entitled *The Changing Search for Employees* reported that 71 percent of small employers felt that qualified employees are "hard" to find, compared to 29 percent who said they "are not hard" to find (Dennis, 2001). Addis (2003) contends that small employers are still plagued by the lack of employees with basic reading and math skills. As an example, workers with inadequate reading skills are not able to interpret operating instructions for machinery properly and may not comprehend warning signs. A 2004 Administristaff survey of small and medium businesses in the United States found that the most significant problem facing these organizations was finding and retaining competent employees. Although respondents were somewhat optimistic about the future, they were concerned about providing adequate training and motivation for employees (Administristaff, 2005). Finally, the Bureau of Labor Statistics projects that during the next decade, 30 percent of new jobs will require some postsecondary education or vocational training (Carnevale, 2005). As might be suspected, employees with postsecondary education are more trainable.

Many perceive that a lack of skilled workers will affect an organization's ability to grow and prosper. This perception is particularly true for small and medium enterprises which continue to create the majority of new jobs in the United States. If current projections and research findings hold true, owners and managers will have to look for less qualified employees that will require more training and development in order to be productive as well as find ways to retain existing productive employees while continuing to train and develop them. Therefore, training and development of human resources has become the unspoken competitive advantage. Small and medium enterprises must consider employees as an investment much like new machines and apply the same effort to keep employees well maintained. To do this, they must overcome the barriers to training.

### **WHY DON'T EMPLOYERS TRAIN?**

There are five main reasons why owner and managers tend not to train and develop their employees (Tracey, 2001). First, they simply do not have the time. Managers are so busy doing more and more with less and less that they lose sight of their employees being an important competitive advantage. Second, they do not know how to give employees the training they need. More often than not, managers avoid the things they do not understand or know how to do. Third, they do not know what materials to use. There is an abundance of information in the marketplace, and the problem becomes choosing what is relevant to the individual necessitating the training. Fourth, the managers do not know how to follow up. A major concern is that managers do not know how to measure or evaluate whether the training is effective. Lastly, managers do not know how to get people to apply the new skills learned in training or to evaluate whether transfer of learning has occurred.

## **WHY DO EMPLOYERS TRAIN?**

Employers provide training and development for their employees for a variety of reasons. They may wish to orient new hires to the organization or teach them how to perform in their initial assignments. Some organizations also wish to improve the current performance of employees who may not be working as effectively as desired, or to prepare employees for future promotions or upcoming changes in design, processes, or technology in their present jobs (Fisher, Schoenfeldt, & Shaw, 1999).

Training may help an organization succeed in a number of ways. Traditionally, training facilitates the implementation of strategy by providing employees with the skills and knowledge needed to perform their jobs. Training also assists in solving immediate organizational problems. Finally, to stay abreast in a highly competitive and turbulent environment, it has been suggested that training and development must foster a continuous learning culture and stimulate managers to reinvent their corporations (Martocchio and Baldwin, 1997).

Over 21 million new jobs have been created since 1991, and most have been in small businesses (Dennis, 2001). Employers in these small organizations are increasingly sensitive to the need for flexible employees in the workplace. Ultimately, many small employers have learned the hard way that it is usually cheaper to retain and retrain workers than fire and rehire (Wells, 2001). As a result, ongoing training and development of employees in small and medium enterprises is essential to the success of the organizations. Education of current employees, whether by having them attend a seminar, conference, or a course at a local college, not only helps them work more effectively but can help with employee retention by making employees feel that the employer values their contributions to the organization enough to train them (Heathfield, 2002).

## **WHAT DO THE EXPERTS SAY ABOUT EMPLOYEE TRAINING?**

In 1990, 66 percent of German workers were involved in apprenticeship training programs, while only two-tenths of one percent of American workers were involved in similar programs (Carnevale, Gainer, & Meltzer, 1990). In addition, on average, American businesses only spend about one-third as much as Japanese companies on training per year (Noe, 1998). Some statistics also suggest that only 16 percent of American employees have ever received any training from their employers (Noe, 1998).

Approximately 70 percent of employers provide some formal training (Noe, 1998). The larger the organization, the more likely its employees have been trained. In one research study, 75 percent of respondents in firms with fewer than 500 employees received some training, compared with 82 percent in companies with more than 1,000 workers (Schaaf, 1998). According to Noe (1998), smaller to midsize firms, employing 100 to 499 people, averaged \$140,040 per company for training; these companies make up about 78 percent of the Dun & Bradstreet database of 146,837 organizations in the United States. Those businesses employing between 500 and 999

people, about 10 percent of the database, planned to spend about \$237,600 each on training. The largest companies, those with 10,000 or more employees (one percent of the database), had training budgets that averaged well over \$15 million. Of particular importance, small companies (50-99 employees) spend about one-third as much as large employers (500+ employees) (Noe, 1998). Most training and development, however, is provided to managerial, supervisory, white-collar, and salaried employees (Mincer, 1997). Yet, 80 percent of people at work today are hourly workers. Interestingly, people who in the past have received training are more apt to undergo further training in the future (Mincer, 1997).

Clearly, small businesses can raise productivity by training and developing their employees. Training ensures that the right people learn the right things at the right time and in the right priority order (O'Connor, Bronner, & Delaney, 1996). As a result, training and development is one of the primary ways to bring less-qualified employees up to acceptable standards of performance and to increase their productivity in a time of global competitiveness (Lichtenstein, 1992). In the long run, the only sustainable source of competitive advantage is an organization's ability to learn faster than its competition (Senge, 1994). Small businesses especially must train and develop their employees due to the size and quality of the labor market that has been projected for the next decade. According to Dennis (2001), 64 percent of small employers have elected to increase training in response to labor shortages. What types of training and development are small and medium enterprises utilizing? More importantly, what types of training and development are needed in small and medium enterprises?

## **SURVEY METHODOLOGY**

A mailed questionnaire paralleling questionnaires used by Solomon and Fernald (2000-2004) was sent to a stratified random sample of small business owners and managers who were members of one or more area chambers of commerce in West Texas. The survey requested a wide range of information pertaining to the areas in which the small business owners and managers and their employees need the most training and development, what methods they currently use to train and develop, and the delivery options used in the training and development process. Demographic data were also gathered. Various statistical analysis using SPSS PC+ 13 were employed on the data.

## **SURVEY RESULTS**

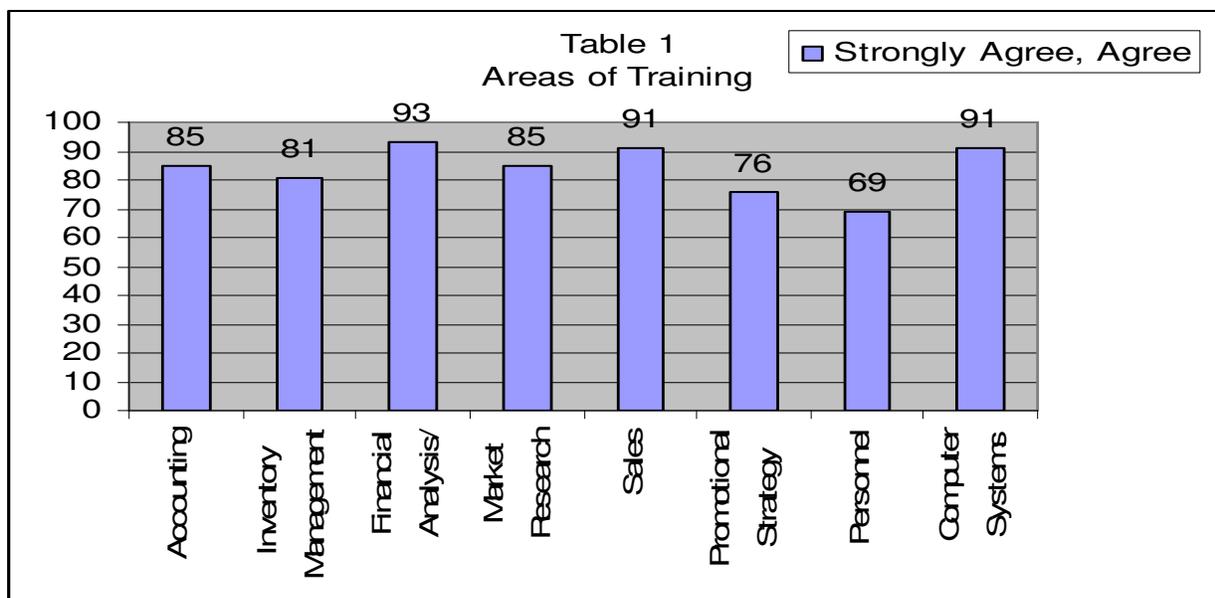

Fifty three businesses returned the mail surveys and their data were analyzed to form the basis for the pilot study. For the purpose of this paper, we will only examine three issues. First, which areas of training do employees need to better compete in today's marketplace? Second, which methods/tools does the business use to train employees? And, finally, which areas of training do the managers in the business need to better execute their responsibilities and duties? To begin, we will present a profile of the typical respondent.

### **Profile of Typical Respondent**

The typical respondent was male (71%), predominantly between 36-45 years of age (48%). Respondents had either a college education (34%) or had attended some college (30%). Their businesses were predominately professional (26%) or service (26%). The typical business has been in existence from one to 73 years with the mean being 20 years.

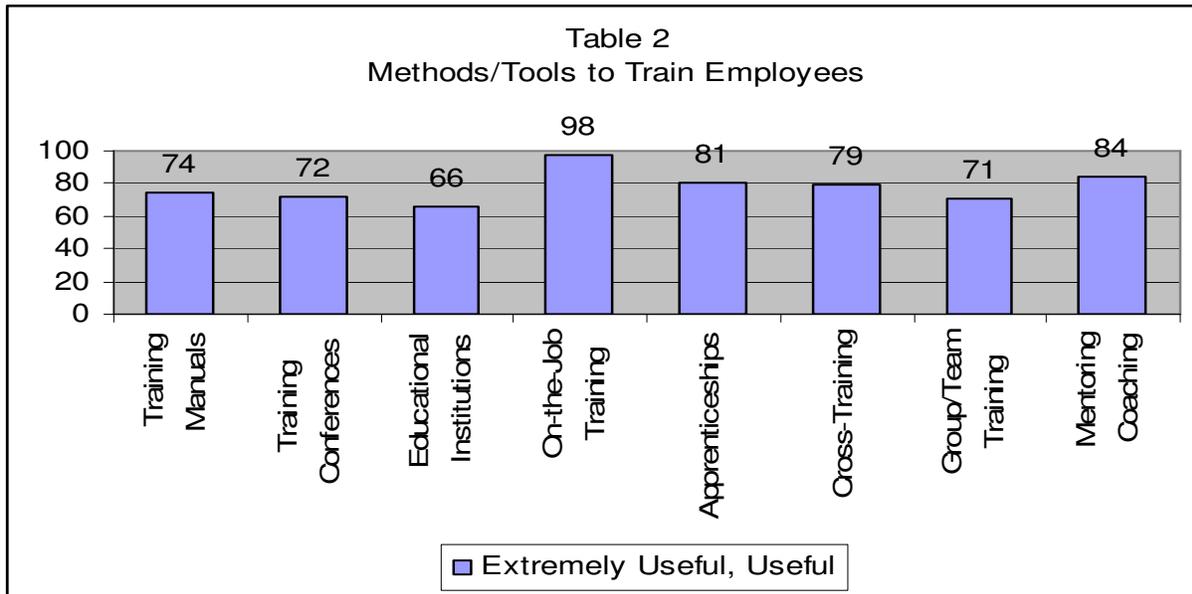

### Areas of Training Employees Need

Owners and managers were asked to indicate which areas of training their employees need to better compete in today's marketplace. Of the twelve possible choices, the responses to the top eight are displayed in Table 1. Respondents strongly agreed or agreed that the top training areas their employees need were financial analysis (93%), sales (91%), computer systems (91%), accounting (85%), market research (85%), and inventory management (81%). The data tends to indicate that those training areas dealing with the operational system of the business and the marketing of the business are the most needed in small and entrepreneurial businesses.

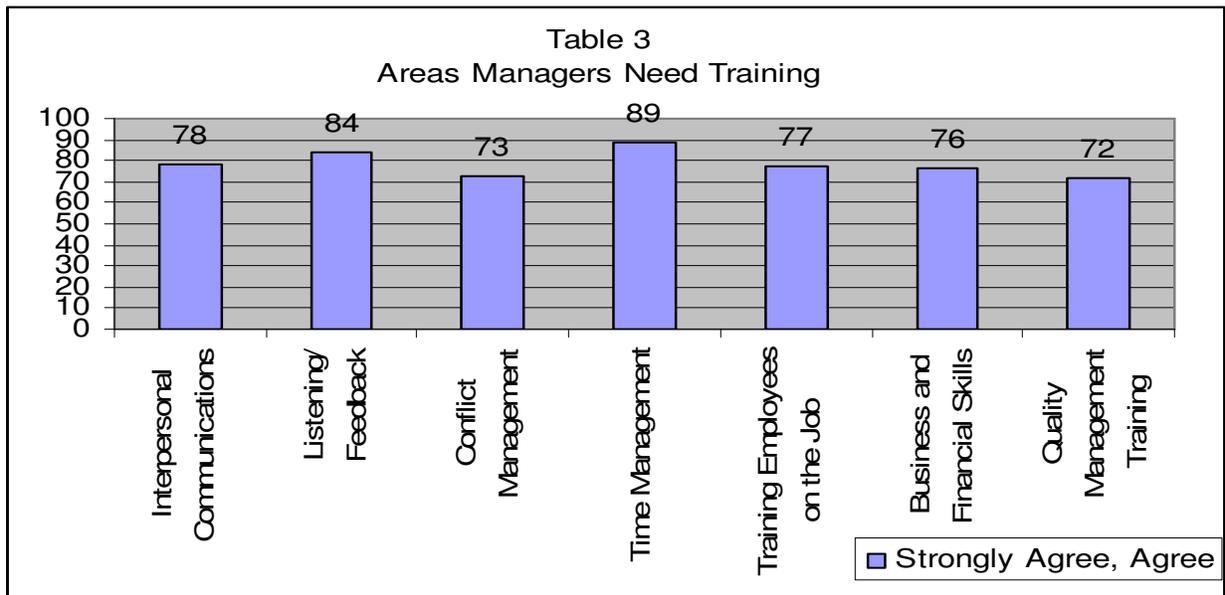

### Methods/Tools Used to Train Employees

Owners and managers of small and entrepreneurial firms were asked to indicate which methods/tools they use to train their employees. Of the 15 possible methods/tools, the top eight methods/tools are displayed in Table 2. Respondents indicated that the top training methods/tools that were extremely useful and useful were on-the-job training (98%), mentoring/coaching (84%), apprenticeships (81%), cross-training (79%), training manuals (74%), training conferences (72%), group/team training (71%), and educational institutions (66%). The data tends to indicate that most respondents believe that face-to-face training more likely done at the business is the most useful.

#### Areas of Training Owners and Managers Need

Respondents were asked to indicate which areas of training and development small and medium enterprise owners and managers need. The top eight areas of management training are displayed in Table 3. Respondents strongly agreed or agreed that training related to time management (89%) listening/feedback (84%), interpersonal communications (78%), training employees on the job (77%), business and financial skills (76%), conflict management (73%), and quality management (72%) were needed. They also perceived that owners and managers, by and large, need to have excellent people skills and also be able to handle specific operational problems such as financial and quality management. Respondents also indicated that training employees on the job is an essential factor in the success of their firms.

### CONCLUDING REMARKS

The literature indicates that today's small and medium enterprises are not providing enough training and development for their employees to be competitive. The pilot survey results provide information on the types of training that are needed for small and medium enterprise employees, methods/tools that are being used to train these employees, and the areas in which small and medium size business owners and managers need training. Generally, the data suggests that training dealing with the operational system and the marketing of the business is most needed by employees. Specifically, training in financial analysis, sales, computer systems, accounting, market research, and inventory management were reported as most important for small and medium enterprise employees.

The top training methods/tools used to train small and entrepreneurial firm employees were on-the-job training, mentoring/coaching, apprenticeships, cross-training, training manuals, training conferences, group/team training, and educational institutions. These responses are consistent with both the literature and anecdotal evidence showing that small entrepreneurs rely primarily on workplace training, or training conducted on site by the owners and managers and their employees.

Small and medium enterprise respondents reported that owners and managers, by and large, need to squeeze more productivity out of their workdays through better time management, be able to initiate, build, and maintain relationships, and also be able to handle specific operational problems such as financial and quality management. Respondents also realize that because training employees on the job is an essential factor in the success of their businesses, they themselves need training and development in order to supervise and conduct such training.

The results of this pilot study may be used to assist small and medium enterprise owners and managers as well as researchers to gain a better understanding of the training needs and methods used to conduct training, for both employees and owners and managers. It must be reiterated, however, that this is a pilot study which needs to be conducted with a larger sample size before we can be confident in generalizing the results

# **CUBAN AMERICAN ENTREPRENEURS: CHAMPIONS OF ECONOMIC DEVELOPMENT IN FLORIDA<sup>1</sup>**

Bella L. Galperin  
John H. Sykes College of Business  
The University of Tampa  
401 W. Kennedy Blvd.  
Tampa, FL 33606-1490  
Tel: 813-235-6221 x 3506  
Fax: 813-258-7408  
Email: [BGalperin@ut.edu](mailto:BGalperin@ut.edu)

Based on the old institutional theoretical approach of ethnic development, this paper presents a historical perspective of the role of Cuban American entrepreneurship in the economic development in Florida. The importance of ethnic small businesses in the economic progress of immigrant groups and the community is discussed. Specifically, the development of the Cuban American community in Tampa, Florida is examined. The factors that have contributed to the economic success of Cuban Americans are reviewed. Finally, future opportunities for Hispanic small businesses are discussed.

## **INTRODUCTION**

Entrepreneurship has played an important role in the economic progress of several ethnic minority groups in the United States, including African Americans, American Indians, Asians, and Hispanics. Hispanic-owned businesses account for the largest category of minority-owned firms in the United States. A report of the U.S. Small Business Administration indicates that there were 1.2 million Hispanic-owned firms in 1997, which represented a 30% increase from 1992 (U.S. Small Business Administration, 2001, March 22). Hispanic Business Inc., however, estimates that there are over two million Hispanic-owned businesses in the U.S. and this number is expected to increase to over three million by 2010 (HispanTelligence, 2004).

Although Cubans Americans only represent a small percentage of the Hispanic population (U.S. Census Bureau, March 2002), Cubans have achieved a remarkable success among Hispanic ethnic entrepreneurs (e.g. Peterson & Roquebert, 1993). In particular, the growth of ethnic entrepreneurship of Cubans in Miami, Florida has been most remarkable. The literature describes the central role of Cuban entrepreneurs in the transformation of Miami from a decaying and stagnant city to a booming economy (Rieff, 1987). While South Florida remains an ethnic enclave which has contributed to the entrepreneurial success of Cubans, few people are aware of the important role that Cuban entrepreneurs have historically played in the economic development of cities on the West coast of Florida, such as Tampa. In fact, the vision of Hispanic entrepreneurs was responsible for the birth of Ybor City which is now a part of Tampa. These entrepreneurs were instrumental in changing Tampa from a sleepy fishing village into the leading cigar manufacturing capital of the world by 1900 (Westfall, 1985).

---

<sup>1</sup> The author would like to kindly thank Veatrice Farrell, Ana Beatriz Hale, Ken Hornung, Yanina Rosario, Sarah Sadd, and Frances A. Wimberley.

Based on the old institutional theoretical approach of ethnic development, this paper presents a historical perspective of the role of Cuban entrepreneurship in the economic development in Florida. First, the importance of ethnic small business in the economic progress of immigrant groups and the community is discussed. Specifically, the development of the Cuban community in Tampa, Florida is examined. The factors that have contributed the economic success of Cubans are reviewed. Finally, future opportunities for Hispanic small businesses are discussed.

## **THE IMPORTANCE OF ETHNIC SMALL BUSINESSES IN ECONOMIC PROGRESS**

When immigrant populations settle down, they are generally faced with a number of difficulties in finding entry-level jobs. Immigrants who find entry-level positions are often alienated from the main group of structured mobility with the labor market. Namely, language barriers and inadequate skills often prevent immigrants to enter positions that required some form of apprenticeship training or qualifying exams (Waldinger, Aldrich & Ward, 1990). In addition, the current economic situation may further reduce the likelihood of successful economic adaptation of these new immigrant groups (Waldinger et al., 1990). With the increased development of technology and global competition, the gap between the job requirements and immigrant skills often become a greater concern for these societies. In search of a solution, entrepreneurs begin to view the creation of ethnic small businesses as an alternative for increased economic mobility.

In the United States, small businesses have played a central role in the economic progress of several earlier immigrant groups, such as Chinese, Italians, Greeks, Hispanics, and Jews (Rajman & Tienda, 2000). By the 1980s, a substantial number of immigrants who moved to the United States chose self-employment. Statistics from the 1980 Census show that approximately 10% of male immigrants who arrived in the United States between 1965 and 1980 were self-employed (U.S. Department of Commerce, 1980). These trends have also been seen in other countries around the globe. For example, the percentage of Indian males in self-employment in England increased from 6% in 1971 to 18% in 1982 (Ward & Jenkins, 1984).

Despite the environmental obstacles faced by all immigrant groups, it became evident that success rates among various ethnic minorities groups differed. In the United States, for example, Cubans and Koreans have been more successful at establishing small businesses compared to Mexicans and Filipinos (Light & Rosenstein, 1995). Chinese and Cypriot immigrant small businesses dominated the fish and chip trade in England (Ward, Randall & Kremer, 1986). Although much of the literature has focused on the role of ethnic small businesses in the economic progress of the immigrant experiences, ethnic small businesses have also contributed to the economic development of communities. Cypriots and Asians were responsible for reviving London, England's weak East End clothing trade (Saifullah, 1979). Chinese small business owners who settled in France during 1975 also played a role in the development of a business sector in the 13<sup>th</sup> arrondissement (Guillon & Taboada-Leonetti, 1986). Cubans have also been central in the economic revival of cities in Florida, such as Miami and Tampa.

## **CUBANS ENTREPRENEURSHIP IN FLORIDA**

A little more than 30,000 people resided in the United States just before the Cuban revolution of 1959 (Portes & Bach, 1985). Political turmoil caused the first major exodus from Cuba to the

United States in the mid-1800s. Cuban political exiles plotting to overthrow Spanish rule took refuge in three U.S. cities -- New York, Key West, and Tampa (Boswell & Curtis, 1984). Several entrepreneurs in the cigar industry followed in the 1860s and 1870s by moving their operations from Havana to these three cities. The cigar companies provided additional employment opportunities for Cuban immigrants (Jaffe, Cullen, Boswell, 1980). By the 1930s, Miami, became the center of Cuban influence because it received huge numbers of exiles fleeing the effects of the revolution against Gerardo Machado. The growth and success of Cuban entrepreneurs in Miami has been well documented in the literature. The Cuban community in Miami has been accompanied by the development of an ethnic enclave (Peterson & Roquebert, 1993) and continues to be the center of a thriving entrepreneurial community. Few people realize that the pioneering Cubans living in New York and Tampa contributed to the success of Cuban entrepreneurs in Miami. Exiles who emigrated after the introduction of communism in Cuba greatly benefited from the experiences of earlier Cuban immigrants since their experiences and moving accounts of living conditions in the United States were captured in books, songs, folktales, and poetry.

Cuban Americans also played a central role in the economic development of Tampa, another city in Florida. In fact, Tampa's growth and prosperity was a result of the vision and efforts of Hispanic entrepreneurs. Ybor City, a section of Tampa, owes its birth to Cuban and Spanish-born entrepreneurs, such as Ignacio Haya and Vicente Martinez Ybor. These men were instrumental in making Tampa the cigar industry center by the 1900s. Ybor, a Spanish born native who immigrated to Cuba in his youth, became one of the early founders of the cigar industry in Havana, Cuba. He moved to Key West, Florida in 1869 after his life was threatened by Spanish agents for assisting the Cuban revolutionaries (Westfall, 1982). Ybor opened new production facilities in Key West and prospered there until 1885 when a strike convinced him to look elsewhere. Haya, another cigar manufacturer who lived in New York, shared Ybor's labour frustrations. Both entrepreneurs were searching for a new location.

After a visit to Tampa, Ybor and Haya were convinced that the environmental conditions were ideal for cigar production. The climate was warm and its location and its proximity to Cuba facilitated the importation of tobacco. A new railroad was under construction and it would further improve Tampa's strategic location for market distribution (Westfall, 1986). Although there were few local laborers available for cigar making, they did not consider it a major problem. Ybor and Haya hoped that the workers would be content in the new surroundings and there would be less labor organizations. Ybor and Haya chose land two miles northeast of Tampa for their factories (Westfall, 1985). The new industrial community, called Ybor City, was founded in 1885. Although Haya was one of the original founders of the cigar industry of Ybor City, the honor of naming the new business community went to Ybor (Westfall, 1985). Largely influenced by the trend of some American entrepreneurs to develop their own functional communities, Ybor began to plan a community to support the cigar factories by building homes for workers and commercial buildings. By the end of 1886, Ybor and his partners built 176 homes. These houses were considered superior to the worker dwellings in Key West or Havana and were used as an incentive for workers to move to Ybor City.

Ybor City was incorporated into the municipality of Tampa in 1887. The population of Tampa grew to 5,500 people in 1890 from 770 inhabitants in 1880 (National Park Service, 2004).

Although the majority of the residents in Ybor City were Cubans, the city also attracted immigrants from Spain and Italy (National Park Service, 2004). The inhabitants of Ybor City mainly made their living from cigar making and occupations related to the cigar trade. The growth of Ybor City also created a large demand for a range of commodities. Entrepreneurs quickly capitalized on the needs of the cigar workers by selling groceries, dry goods, pots and pans, and fabrics. Many Cuban entrepreneurs opened cafés, which eventually became the hub of daily social life in Ybor City. The Columbia Restaurant, currently Florida's oldest restaurant, was opened by Casimiro Hernandez who was born in Cuba. The Columbia Restaurant, now said to be the world's largest Spanish restaurant, started in 1905 as a small corner cafe serving authentic Cuban sandwiches and *café con leche* (coffee with milk) (Cavanaugh, 2003).

Eventually, Ybor City surpassed Havana as a manufacturing center of quality cigars and became the "Cigar Capital of the World" (National Park Service, 2004). Ybor City was also known as "Little Havana" as most of the residents preserved Cuban traditions and cultures. Ybor City continued to prosper through the 1920 and early 1930s, but by the end of the 1930s several factors contributed to its decline. These factors include increases in cigarette consumption, an economic depression, and improvements in technology that made machine-rolled cigars comparable in quality to hand-rolled cigars. In the 1960s, urban renewal and the U.S. embargo on Cuba finally ended Ybor City's long and prosperous reign as, "the cigar capital of the world" (Cavanaugh, 2003). As part of the urban renewal project, seventy acres and several hundred homes and buildings were demolished and leveled to make way for an interstate highway. These changes motivated civic organizations to band together to preserve the city's historic buildings and ethnic heritage (National Park Service, 2004). Protection turned to opportunity in the 1990s when Ybor City experienced an economic resurgence. Ybor City continues to grow and flourish in the present. Although Ybor City is no longer known as, "Little Havana", many people refer to the district as the "Latin Quarter".

Today, approximately 10% of Tampa's population is Latino and several of the nation's most successful Hispanic businesses are located in the Tampa Bay area (Gustafson, 2004). Recent statistics show that Hispanic immigrants in Tampa come from countries such as Colombia, Cuba, Mexico, and Puerto Rico. Cubans are now the third largest group according to the 2000 census (Steele, 2004). Currently, Puerto Ricans represent the largest Hispanic group in the Tampa area with 52,568 residents, followed by Mexicans with 35,321 residents and Cubans with 35,123 residents. Despite changes in immigration patterns, Cuban American entrepreneurs continue to succeed in Tampa. Cuban American entrepreneurs have opened new ventures, such as restaurants, tobacco import retail stores, law and accounting offices, real estate development companies, and advertising businesses. In addition, a number of Cuban American businesses are run by third- and fourth- generation family members.

### **FACTORS CONTRIBUTING TO THE ECONOMIC SUCCESS OF CUBANS**

A number of factors have facilitated the entrepreneurial activities among Cuban Americans in Florida. First, location contributed to the entrepreneurial growth in Tampa. Tampa's port is now Florida's largest and the most important economic engine in West Central Florida. It provides a direct route to Mexico, Latin America, and the Caribbean (Tampa Port Authority, 2005). Second, Cuban American entrepreneurs and workers in the cigar industry have shaped Tampa's traditions

and customs. Cuban consumer products are popular because Cuban heritage permeates Tampa's culture. Although these businesses initially targeted the Cuban immigrant community alone, many now serve broader markets. Third, strong ties within Cuban families have facilitated the growth in the entrepreneurial activities of Cuban Americans. Due to their collectivist culture (Romero, 2004), Cuban Americans entrepreneurs receive strong support from their kinship. Family members will often help to accumulate start-up capital and work in the family business. Finally, strong social networks within the Cuban American community facilitated entrepreneurial activities in Tampa. Because ethnic entrepreneurs have limited resources and less access to mainstream sources of credit and technical assistance compared to others, strong ties are important in the formation and maintenance of immigrant firms (Waldinger et al., 1990).

## **FUTURE OPPORTUNITIES FOR HISPANIC SMALL BUSINESSES**

A number of future opportunities exist for Hispanic entrepreneurs. Several resources are available to Hispanics planning to start a new venture. These resources provide future Hispanic entrepreneurs with valuable training and information to start a business. Organizations that can help future Hispanic entrepreneurs are discussed below.

### **Small Business Administration**

The U.S. SBA, specifically created by Congress to help America's entrepreneurs develop small enterprises, offers a variety of programs, such as federal contract procurement assistance and specialized outreach programs for women, minorities, and armed forces veterans (U.S. Small Business Administration, 2001, March 3). Government programs supporting minority-owned businesses include the 7(a) loan program and the 8(a) business development program (U.S. Small Business Administration Office of Advocacy, 2001). The U.S. SBA has helped thousands of aspiring entrepreneurs from various minority groups over the years; it is expected that these programs will continue to be an important program for future Hispanic entrepreneurs in the future.

### **Office of Supplier Diversity of the State of Florida**

The OSD of the State of Florida's function is to improve business and economic opportunities for Florida's women-owned and minority-owned businesses (Florida's Office of Supplier Diversity, 2005). In line with Governor Bush's One Florida Initiative to embrace diversity in the state of Florida, OSD's primary functions are the Minority Business Enterprise Certification, a program designed to increase the number of minority business enterprises throughout Florida; advocacy and outreach activities which support minority businesses and foster positive relationships; and, matchmaking activities which are designed to build relationships between minority businesses and the community. The OSD also works collaboratively with other organizations, such as Small Business Development Centers (SBDC), The Development Minority Business Development Agency (MBDA), The City of Tampa Minority Business Development Office

### **Tampa Bay Economic Development Corporation**

TEDCO, a U.S. SBA certified development company (CDC), provides funding for projects that expand small business operations and creates job in the community. TEDCO offers various programs, such as SBA's CDC/504 loan program. The CDC/504 loan program is a long-term

financing tool for economic development within a community, including the expansion of minority business development. The CDC/504 program provides growing businesses with long-term, fixed-rate financing for major fixed assets, such as land and buildings (U.S. Small Business Administration, 2005). The CDC/504 program is available to small business owners, regardless of minority status, and provides valuable assistance to all Americans, including Hispanics. Although TEDCO does not specialize in funding opportunities for Hispanic businesses alone, the Women/Minority Business Fund, a privately funded program, is designed to foster the economic development and financial growth of minority-owned businesses located within the incorporated City Limits of Tampa. Ken Hornung, President, explained that in order to be eligible for the program the business must be owned by a minority; that is a 51% or more of total ownership (personal communication, January 12, 2005). The Women/Minority Fund can provide prospective Cuban American entrepreneurs with funding opportunities.

### **Tampa Bay Black Business Investment Corporation**

The Tampa Bay BBIC, a nonprofit corporation, was incorporated as a public-private partnership between local government and the corporate community. The purpose of the Tampa Bay BBIC is to advance the economic well being of African-American-owned businesses in Hillsborough and Pinellas Counties (Tampa Bay Black Business Investment Corporation, 2005). Tampa Bay BBIC is also the loan intermediary for the U.S. SBA Pre-qualification Loan Program, a loan program available to any business that is at least 51% owned and operated by a racial or ethnic minority, woman or veteran. Frances A. Wimberly, President of the Tampa Bay BBIC, and Veatrice Farrell, Vice President of the Tampa Bay BBIC, explained that the program was originally restricted to women and minorities but the U.S. SBA recently expanded eligible borrowers to include veterans (personal communication, January 6, 2005). The Tampa Bay BBIC also is a loan intermediary for the U.S. SBA Small Office Home Office program, another loan program in which loan proceeds can be used for equipment and machinery, working capital, or business expansion. Although the programs offered by BBIC are more inclusive, prospective Cuban American entrepreneurs can certainly benefit.

### **Tampa Bay Hispanic Chamber of Commerce**

TBHCC, a private not for profit organization, is dedicated to building the community through business and creating a climate in which Hispanic businesses can flourish. Its mission is to serve the community while energizing Hispanic businesses and the economic growth of Tampa Bay (Tampa Bay Hispanic Chamber of Commerce, 2004).

### **Ybor City Chamber of Commerce**

The Ybor City Chamber of Commerce is a membership organization that represents and assists local businesses (Ybor City Chamber of Commerce, 2005). The Chamber is dedicated to the preservation, revitalization and growth of Tampa's National Historic Landmark District. Its mission is "building strength through members." While the Chamber strives to increase the diversity, Ana Beatriz Hale, Membership and Marketing Director, stated that a substantial proportion of its members are Hispanics. She noted, "I would say 50% of the members of the Chamber are ethnic entrepreneurs--either first, second, third or fourth generation or people who have recently immigrated to the United States." (personal communication, January 6, 2005). The Chamber provides prospective Cuban American entrepreneurs with a wide range of promotional and marketing opportunities which enable them to expand their potential client base. Prospective

Cuban American entrepreneurs also have access to a range of networking events, such as monthly membership luncheons and evening receptions.

### **Hispanic Business Initiative Fund**

The HBIF, a non-profit corporation registered in the state of Florida, provides technical assistance in English and Spanish for Hispanic entrepreneurs and Hispanic-owned businesses. It provides a variety of management training programs, professional services and specialized technical assistance for Hispanic entrepreneurs. For example, HBIF offers an orientation seminar for prospective entrepreneurs, which provides information on how to start a business. Yanina Rosario, Vice President HBIF, West Coast, noted, "This is a seminar that is provided to them (clients) free of charge. We walk them through the realities of stating a business. Licenses, permits, the financing process..." (personal communication, January 12, 2005). HBIF also counsels individuals who want to expand their businesses and assists with business certifications for entrepreneurs interested in participating in procurement programs. HBIF is able to provide these services free of charge because of support from grants and donations.

In conclusion, Cuban American entrepreneurs have played a central role in the economic development of Florida. Specifically, the vision of Hispanic entrepreneurs was responsible for the birth of Ybor City and the development of Tampa. Despite changes in Hispanic immigration patterns in Tampa, Cuban American entrepreneurs continue to succeed and partake in the development of the city. Given the numerous resources available to Hispanics interested in starting new businesses, it is expected that prospective Cuban-American entrepreneurs will experience greater success.

\* A preliminary draft of this paper titled “Financial Planning in New Venture Creation” was presented at the 27th ISBA National Entrepreneurship and SME Development Conference, held in Newcastle (U.K), in November 2004. The author would like to thank Klaas Dannen, Thomas Frank, Sina Heinemann, Alfred Luhmer, and Matthias Raith for critical comments and suggestions as well as Sandra Liebert for technical support. Financial support by the KfW Mittelstandsbank is gratefully acknowledged.

# **Toward a Framework of Financial Planning in Business Venturing – Demonstrated by a Case Study**

*Benjamin B. Gansel*

## **Abstract**

*We develop a coherent comprehensive framework for financial planning in business venturing. It is imperative to build a practical guideline that exhibits the financial assumptions, connections, and implications of business venturing which can be verified and tested. The whole framework can be interpreted as a linkage of decisions that provide a “sphere” within which entrepreneurial planning proceeds, strategies are quantified, decisions are made, and subsequent actions take place. This article demonstrates the applicability and employment of our financial planning framework based on a case study.*

*The foundation of the planning process comprises five interrelated financial planning elements: planning of sales, recurring expenditures, nonrecurring investments, capital requirements, and financing. This provides the groundwork for generating the financial statement. As a consequence of the decision analytic foundation, the robustness of the financial plan can be tested by employing sensitivity analysis, scenario analysis, and simulation. The implications are twofold: Firstly, our financial planning framework provides a practical guideline that aids entrepreneurs to obtain a deeper insight and thorough understanding of the financial magnitude of their present decisions. Secondly, We demonstrate that financial planning is a quantification of the corporate strategy and emerges from the action upon discovering an entrepreneurial opportunity. Thus, financial planning is strategically driven. Both are interrelated.*

## **1. INTRODUCTION AND REVIEW OF LITERATURE**

Financial planning is one of the most important but also difficult hurdles to overcome when planning a new venture. This topic has been discussed in several articles (Frankston, 1981; Gumpert & Stancill, 1986; Hayen, 1982; Hergert, 1987; McGrath & MacMillan, 1995). In addition, financial planning techniques for large-scale and international enterprises are not fully appropriate for dealing with start-up planning. Yet, there exists no generally accepted practical guideline for aligning financial planning with business venture creation. A coherent comprehensive framework which draws out interdependencies among the planning functions and financial items is still lacking (for notable exceptions see Gumpert & Stancill, 1986; McGrath & MacMillan, 1995). The importance of planning in business venturing is supported by recent research which has detected a positive correlation between planning intensity and the success of new ventures (Kugler, 2003; W. H. Stewart, Watson, Carland, & Carland, 1999). Several empirical studies highlight the positive signaling effect of a business plan (see, for example Delmar & Shane, 2003; W. H. Stewart et al., 1999; Zimmerman & Zeitz, 2002). Furthermore,

there is a significant positive relationship between formal planning by small firms and financial performance (see, for example Bracker & Pearson, 1986; Schwenk & Shrader, 1993).

Because of this gap we have developed a more appropriate framework for dealing with financial planning in business venturing. Our purpose is to conceptually aid entrepreneurs to obtain a deeper insight and thorough understanding of the financial magnitude of their present decisions. It is imperative to build a practical guideline that exhibits the financial assumptions, connections, and implications of business venturing which can be verified and tested. The framework also allows an analysis of “what if” questions. The purpose of this article is to demonstrate the applicability and employment of our financial planning framework based on the case of one real venture – “BioDup” – which is introduced in the following paragraph.

BioDup tries to enter the market of real-time thermocyclers which is dominated by big diversified biotechnology companies. While the product lifecycle for conventional thermocyclers is said to be in downturn, the market for real-time thermocyclers is expected to grow in subsequent years. Real-time thermocyclers duplicate DNA sequences in large numbers. The device developed by BioDup considerably shortens the process and can be produced at lower manufacturing costs. Both features are superior to competitor products. At the beginning, academic institutes and pharmaceutical company laboratories are the primary target market in Europe. In order to protect privacy we make the case anonymous.<sup>1</sup>

## 2. BACKGROUND

Our conceptual starting point of the financial planning framework is the entrepreneurial discovery approach, which, to a large extent, emerged in the Austrian school of economics, embedded in Kirzner's explanation of existing tendencies “... toward continual discovery and exploitation of pure profit opportunities thus tending to nudge the market in the equilibrative direction” (Kirzner, 1997, 67). The entrepreneurial discovery is characterized as “alertness” to available opportunities at which the entrepreneur takes advantage on such discoveries (Kirzner, 1973, 1997, 1999). The role of the entrepreneur can be described by taking innovative action upon discovering entrepreneurial opportunities, which nudges a dynamic process of changes whose tendency is equilibrative.<sup>2</sup> In doing so, entrepreneurs bear the risk of failure by financing themselves (Evans & Jovanovic, 1989). Kirzner (1997)<sup>3</sup> seems to suggest that perceptive entrepreneurs base their judgment on monetary calculations. Although, the pure discovery of an opportunity does not incur opportunity costs, taking action on an opportunity requires planning and calculation which is demonstrated by Minniti and Koppl (2003; 1999) using Kirzner's instantaneous arbitrage. In addition, the calculation strongly depends on the entrepreneurs' personal characteristics, due to the subjective perception of opportunities arising from personal access to information and experience as well as individual interpretation (Casson, 2003). Thus, entrepreneurs are facing different cost estimates when acting to exploit the discovered opportunity (Minniti & Bygrave, 1999).

As this perspective reveals, the profitable exploitation of opportunities is related to the task of systematic planning and the calculation of costs and revenues. So far, it is unexplained how the

potential entrepreneur conducts such calculations. There exists no generally accepted practical guideline for aligning financial planning with business venturing. Before discussing our framework, we define *financial planning* as the process of systematic and quantitative estimating of all cash in and outflows relevant for the exploitation of entrepreneurial opportunities, in order to deal with the futurity of present financial decisions (Drucker, 1959, 239). Thus, financial planning is the notional anticipation of future outcomes and the application of an appropriate decision making mechanism for dealing with uncertainties. As the project develops, the financial plan evolves and the real potential of the venture reveals (McGrath & MacMillan, 1995)<sup>4</sup>. Distinct from the definition of financial planning, the pro forma *financial plans* are the numerical results of the planning process.

Two sets of financial plans are necessary, one for internal planning purposes and one for banks, creditors, and stockholders, whereas the latter can be extracted from the internal planning process. The decision whether to act upon a discovery must not be fully based on generally accepted accounting standards (for an contrary point of view, refer to Gumpert & Stancill, 1986), as decisions in business venturing can be made independently from accounting practices. However, a framework of financial planning may be partly based on accounting standards. External addressees extensively see the financial plan, within the business plan, as a starting point for investment and financial decisions (for example Penman, 2001). Potential financiers expect to see and analyze specific details (Castrogiovanni, 1996). Hence, the official financial plan must conform to accounting practices of the government. As an internal planning instrument, financial planning primarily supports the decision making process. It should be viewed as a quantification of the specific corporate strategy emerging from the action upon discovering the opportunity. Thus, financial planning should have a strategic focus. Our framework can, thus, be interpreted as a linkage of decisions that provide a “sphere” within which entrepreneurial planning proceeds, strategies are quantified, decisions are made, and subsequent actions take place. In this sense, the financial plan for external purposes can be described as a “by-product” extracting from the internal planning process and conforming to accounting standards.

### 3. CONCEPTUAL FRAMEWORK

The financial planning process, regarded as a set of decision making instruments, requires the (monthly or periodically) planning of five related elements, defined as financial (planning) elements: (i) Planning of Sales; (ii) Planning of (recurring) Expenditures; (iii) Planning of (nonrecurring) Investments; (iv) Planning of Capital Requirements (both recurring expenditures and nonrecurring investments); (v) Planning of Financing. The production plan is derived from the planning of sales. A key instrument, defined as “Footnotes”, contains information on principles, assumptions, details, connections, schedules, and methods used to produce the financial planning elements (McGrath & MacMillan, 1995; Stancill, 2004). This provides the groundwork for the planning process. Financial planning elements are on a cash flow basis (Frankston, 1981). It is often the case that financial planning is heavily infected by accounting standards focusing on earnings and treating cash as a derivative rather than the center of attention (Howell, 2004). Figure 1 serves as a comprehensive overview for the following discussion. Planning of the financial elements provides the informational foundation to generate a pro forma

financial statement that includes the income statement, balance sheet, and cash flow statement (dotted lines).

Figure 1 about here

#### **4. PLANNING OF FINANCIAL ELEMENTS**

A crucial issue arising with any conceptual framework is the determination of the starting point. In contrast to existing enterprises, start-ups cannot take advantage of past financial data and an accounting information system. Because of the preceding market analysis, the planning of sales is a recommended starting point. Upon discovering the opportunity and analyzing the market, the entrepreneur continuously values the opportunity. The process results in the sales volume and price extracted from the preceding market analysis of estimated market needs and from a written justification of sales forecasting. Because sales volume and price is our starting point, this can be interpreted as an anchor for other planning elements, that is financial planning is driven by demand. The procedure described up to this point is demonstrated on the case study in the following paragraph.

The vision of BioDup entrepreneur's is to equip pharmaceutical researchers worldwide with a real-time thermocycler making their daily work more efficient and speed up the development process of pharmaceutical drugs. Within the first two years, academic institutes and pharmaceutical company laboratories are the primary target market in Europe. With more experience in the production and distribution process they pursue to expand geographically and in related industry markets. The key success factors of BioDup are twofold: First, the device developed by BioDup considerably shortens the process of DNA duplication and secondly, it can be produced at lower manufacturing costs. Both features are beneficial to customers and superior to competitor products. This competitive advantage is supported by a patented technology protecting the innovation because most parts of the device are delivered by vendors and, thus, leaving only the final assembling to BioDup. The technology has been developed in the university. However, a critical concern regarding the strategy reveals at this planning stage. Solely competing on the basis of a higher quality at lower costs than competitors can be an easy strategy to imitate.

An issue arising during the market analysis was related to the difficulty of obtaining sales volume. One market analysis from a consulting company provided only the number of academic institutes and pharmaceutical company laboratories using thermocyclers in Europe. From this analysis, the big three markets in Europe are Germany, United Kingdom, and France bringing together 930 companies and, thus, potential BioDup customers. Taking an average useful life of three years results in a market potential of 300 companies per year and a quantity of minimum replacement investments of 300 thermocyclers per year. Because of BioDup's superior device they pursue to capture at least ten percent of the market share in the first year and 20 percent in the second year resulting in more than 30 and 60 BioDup thermocyclers in sales volume respectively. The market of real-time thermocyclers is expected to grow on average 15 percent over the next two years, around ten percent in year three and afterwards adapting the growth rate of the biotechnology industry. With an average market price of 5.000 US-Dollars, BioDup enters

the market with an aggressive target price of 4.000 US-Dollars due to the fact of lower manufacturing costs.

At the end of year two, BioDup strategy is to expand geographically in the European market including an increase of a market potential of approximately 600 companies per year. With a stable market share of 20 percent, sales volume increases to at least 120 thermocyclers per year. Upon establishment in Europe, BioDup is planning to enter the US market in year three and four. Taking again a look at figure 1 shows that Footnotes are the foundation for generating the financial planning elements. Footnotes document the assumptions necessary to derive the financial plan, indicate the vulnerability of the venture and, thus, are always subject to review, testing, and revision. The key assumption for BioDup should be footnoted as well as reviewed and tested continuously.<sup>5</sup>

This demonstrates that sales volume and price have to be extracted and justified from the preceding market analysis of estimated market needs. Planning of sales determines the scale and scope of the new venture which also establishes the production plan that provides the foundation for planning of recurring expenditures and nonrecurring investments. The former starts with the calculation of production costs (labor, material, overhead, etc.; except depreciation). Secondly, the production plan specifies the required level of capacity of production which ascertains the needs of investments and working capital. This also influences the planning of recurring expenditures. Based on the production level, the entrepreneur calculates the remaining expenditures for administrative, selling, research and development, and other expenditures in order to complete the element planning of expenditures. This provides considerable information to construct partly the income statement.

## **5. FINANCIAL STATEMENT**

The financial statement consists of the income statement, balance sheet, and cash flow statement which could be expanded by statement of stockholders' equity. In this section we demonstrate how to generate each of these statements from the financial planning elements.

## **6. DECISION MAKING**

The issue that needs to be addressed is which approach should guide the entrepreneur in her present decisions. Besides factors such as intuition, feeling, and experience, other important methods include systematic planning and forecasting. Relying on intuition (Allinson, Chell, & Hayes, 2000; Bird, 1988; Bird & Jelinek, 1988) contradicts the fact that planning takes place before taking human action (Locke, Latham, Smith, & Wood, 1990). Simply speaking, the entrepreneur can examine her fundamental assumptions and estimations before investing in tangible or intangible assets. By estimating the timing of cash flows, the entrepreneur anticipates bottlenecks and financial slacks which enhance the allocation of scarce resources. For this, our framework can be interpreted as a linkage of decisions that provide a "sphere" within which entrepreneurial planning proceeds, strategies are quantified, decisions are made, and subsequent

actions take place. A decision made today creates a set of subsequent decisions and alternatives tomorrow (Hammond, Keeney, & Raiffa, 2002). The framework supports the entrepreneur to turn her vision and goals into concrete stepwise activities as well as to make decisions faster based on numerical values than with slower trial-and-error learning (Delmar & Shane, 2003). By knowing and understanding the associated uncertainty, the entrepreneur is able to rationally select among risk taking courses of action, instead relying on intuition, hearsay or experience (Drucker, 1959).

## 7. CONCLUSION

In this article, we develop a coherent comprehensive framework for financial planning in business venturing. The whole framework can be interpreted as a linkage of decisions that provide a “sphere” within which entrepreneurial planning proceeds, strategies are quantified, decisions are made, and subsequent actions take place. A decision made today creates a set of subsequent decisions and alternatives tomorrow. Our framework supports entrepreneurs in turning their vision and goals into concrete steps to be taken. The approach is value-driven meaning that the entrepreneur exploits only value adding opportunities based on her expectations and calculations. The foundation of the planning process comprises five interrelated financial planning elements: planning of sales, recurring expenditures, nonrecurring investments, capital requirements, and financing. This provides the groundwork for generating the financial statement. Finally, the robustness of the financial plan can be tested by employing sensitivity analysis, scenario analysis, and simulation.

## 9. ENDNOTES

<sup>1</sup> To make the case anonymous we have modified three things: The name of the venture, the industry, and the product. In this article, we are describing the real market structure, market volume and price, competitive advantages, cost structure, production plan, investments, and financing as it is in the real case, however, the biotechnology market and the real-time thermocycler is fictitious indicating that they are inconsistent with reality.

<sup>2</sup> There are other ways of understanding the term entrepreneurship (see, for example Baumol, 1993; Casson, 2003; Schumpeter, 1934; A. Stewart, 1991; Venkataraman, 1997).

<sup>3</sup> Kirzner (1997) refers to Rothbard (1994) and Salerno (1993; 1994).

<sup>4</sup> Because of this McGrath and MacMillan (1995) define planning as discovery-driven planning.

<sup>5</sup> Because of the reduced paper version, we neglecting the case study and focusing only on the general procedure from this point.

<sup>6</sup> Although the planning of balance sheet, income statement, and cash flow statement are simplifications, they are for the present purpose.

# USING INFLUENCE DIAGRAMS TO STRUCTURE THE PROCESS OF NEW VENTURE CREATION

Benjamin B. Gansel, Matthias G. Raith

Dept. of Economics and Management  
Otto-von-Guericke-University of Magdeburg

gansel@ww.uni-magdeburg.de  
raith@ww.uni-magdeburg.de

## Abstract

Influence diagrams and decision trees provide a convenient yet powerful approach for modeling, understanding, and evaluating multistage decision problems under uncertainty. Although both instruments are isomorphic, the size of decision trees becomes critical in situations with a high level of complexity. Influence diagrams offer a more compact approach in the structuring and planning phase. They incorporate the complex interdependencies and show the flow of information and decisions. By distinguishing between decision and chance nodes, they provide a precise description and structure of the entrepreneurial decision making process.

In this paper we demonstrate the application of decision making instruments to the financial planning process in new venture creation. The implications of a decision-analytical are twofold: Firstly, influence diagrams and decision trees are excellent methods to construct the scope of plausible future states, to show the flow of information and sequence of decisions, to structure the process of decision making in a more constant and precise way, and to identify critical decisions to be made. Influence diagrams are simple to understand, they are straight-forward to construct, and they provide an optimal basis for computer-aided decision support. Secondly, our approach helps entrepreneurs move beyond intuition. Relying on intuition contradicts the fact that planning takes place before taking human action. Hence, our approach provides entrepreneurs with a deeper insight and thorough understanding of the financial magnitude of their future decisions.

### **Abstract**

According to the Global Entrepreneurship Monitor research project (GEM) women have lower nascent entrepreneurial activity rates than men. In the U.S., the passage of the Women's Business Ownership Act of 1988 (HR5050), provided seed funding for women's business centers through the Small Business Administration. Women's business centers were targeted to provide technical assistance to women for business formation, particularly women who were socially and economically disadvantaged. This study examined the accomplishments of women's business centers throughout the U.S. and found that women's business centers are drivers of nascent entrepreneurship by women. Centers consistently serve clients who are economically and socially disadvantaged. Two-thirds have household income below \$50,000, less than half have more than a high school education, and 42% are women of color. The study data indicates that approximately 40% of women's business center clients are nascent entrepreneurs, well above the national rate of 8.2% found in the 2003 GEM U.S. data. The success of women's business centers can be attributed to shared practices targeted specifically to women's situational needs. Programming tailored to women's interests and needs, a relationship-oriented approach, and networking activities that create a bridge to business culture are key practices consistently used by women's business centers nationwide. Increased funding and community support would enhance the impact of women's business centers and augment a powerful source of nascent entrepreneurship and economic development among disadvantaged women.

### **INTRODUCTION**

The Global Entrepreneurship Monitor research project has consistently shown that women have lower entrepreneurial activity rates than men. Although the United States has the highest level of entrepreneurial activity among G7 and First World countries, the gap in disparity of entrepreneurial activity persists by gender (Acs et. al, 2005). And while 2003 U.S. data shows a bounce back in nascent entrepreneurship to pre-2001 levels for men, the nascent entrepreneurship of women continued to lag (Minniti and Bygrave, 2004). Entrepreneurship is a means for economic development, as new venture creation contributes employment, income and many multiplier effects to an economy. Accordingly, policy implications of the entrepreneurial gender gap include a focus on

training and technical assistance in support of entrepreneurial activity by women. Gnyawali and Fogel (1994) define the “entrepreneurial environment” as a combination of factors influencing the development of entrepreneurship. One portion relates to the economic and socio-political factors that influence individuals’ proclivity and ability to undertake entrepreneurship. The other portion relates to the availability of technical assistance and support for entrepreneurial endeavors. Governments may influence all of these factors. Public policy targeted to the provision of technical assistance to aspiring entrepreneurs should therefore be expected to improve the entrepreneurial environment and new venture creation. Using the framework of expectancy theory, Gatewood (1993) posited various possibilities for the influence of public assistance organizations on new venture creation. This research study looks at the women’s business center movement in the United States, initiated by federal legislation, to ascertain the impact and effectiveness of targeted technical assistance and support for new business creation by women.

With the passage of the Women’s Business Ownership Act of 1988 (HR5050), seed funding for women’s business centers became available through an annual grant process administered by the U.S. Small Business Administration. Women’s business centers were targeted to provide technical assistance to women for business formation, particularly women who were socially and economically disadvantaged. While a few women’s business centers pre-date the 1988 act, most women’s business centers were founded in the early to mid-1990s when a confluence of positive entrepreneurial environment factors, including federal policy, provided a national platform and increased opportunities. Since these entrepreneurial programs targeting women were initially established, they have been steadily expanding their reach – both geographically and demographically; there are now approximately 100 known women’s business centers in the U.S. These community-based centers target education, training, and technical assistance to under-served and under-privileged women, precisely those who are the lagging group of nascent entrepreneurs.

This research study focused on assessing the impact and effectiveness of women’s business centers and includes data from centers in 33 states as well as the District of Columbia. More specifically, the research: 1) describes the diverse profile of existing centers; 2) examines key shared practices; and 3) assesses the opportunities and challenges that women’s business centers confront. This project helps us understand the impact women business centers have on our national economic landscape and the policy implications for how their work can be improved and extended. Our analysis shows that women’s business centers are effective developers of nascent women entrepreneurs through the woman-centered shared practices they bring to technical assistance and support. This paper is divided into the following sections: a) an overview of the methodology used in the research; b) a description of the demographic profile of women’s business centers; c) a discussion of the shared practices that contribute to center effectiveness; and d) the challenges and needs centers face as they seek to continue their work.

## **METHODOLOGY**

The research is based upon survey methods as well as focus groups. Fifty two center directors responded to the research survey. In addition, 34 center directors participated in focus groups. The survey responses, informed by the focus group discussions, form the basis of the data and conclusions in this study.

One-hundred institutions were pre-qualified as women's business centers through phone and e-mail interviews. To be considered a women's business center, organizations had to be: a) a 501(c) 3 non-profit entity; b) focused primarily on women clients starting businesses or, if part of a larger organization, have a dedicated staff focused on women clients; and c) provide short-term and long-term technical assistance, training and business counseling. After piloting the survey with 5 women's business centers, we distributed our 144-item survey. Over half of the identified women's business centers (n= 52) responded, providing a national sample of centers representing a diversity of age, locale, budget, and experience. The majority of centers (87%) have received SBA funding.

Three separate focus groups were conducted in conjunction with national conferences attended by center directors, with a total participation of 34 directors. The focus groups met for approximately one hour; the meetings were tape recorded and transcribed. In addition to participating in the discussion, focus group participants were asked to complete a written form identifying themselves and their center. They also had an opportunity to respond to focus group questions on this form. A written analysis was generated for each focus group based upon the transcription. The focus group discussion protocol concentrated on gender-specific needs of women entrepreneurs, the economic impact that women's business centers are able to make in women's lives and in the community, whether the training at women's business centers affects the way women run their businesses and successful practices at women's business centers.

## **DEMOGRAPHICS OF WOMEN'S BUSINESS CENTERS**

Women's Business Centers were created to assist socially and economically disadvantaged women in starting and building their own businesses, and the data shows that they are indeed accomplishing that mission. Centers range in age from less than a year to 28 years old, but nearly half of the centers are less than 5 years old. Approximately two-thirds of centers have one location only and just over half the centers share their location with another organization. Three-quarters of the centers responding to the survey are located in urban areas with a similar proportion of the less established (under 5 years of age) and more established centers located in urban areas. The majority of standalone centers are located in urban settings. Centers serve clients across a broad spectrum of the community.

In this study, centers reported an average of 79 clients visiting per month, with one center serving as many as 350 clients per month. (Actual activity at centers is no doubt higher as clients tend to visit multiple times per month and directors distinguish between clients served and contacts made. The survey asked only about the number of clients served per month.) There was a significant correlation between center age and the number of clients served per month, with the older centers serving clients at a higher rate. While older

centers on average have more employees, there is no significant correlation between the size of the center's staff and clients served per month. Thus, something besides staffing must account for the increased productivity among the more established centers—perhaps experience. No significant relationships emerged between location (urban vs. nonurban) or co-location and the number of clients served by centers per month. In addition, approximately three-quarters of the centers noted an increase in the average number of clients per month during the past year. The proportion of centers which reported a growth in client rate was consistent across location (urban vs. nonurban), age, and co-location.

Women's business centers serve a demographically diverse and disadvantaged clientele, and the majority of these clients are presently managing a start-up business. While the majority of clients served are women, the centers also serve men, who comprise an average 13% of clientele. Nearly one-half of all clients are considered a member of a minority group, the largest group being African Americans (23%), followed by Hispanics (10%) and Asian Americans (5%). Reflective of the general population, minority representation among clients is higher in the centers in urban areas. Centers consistently are reaching a diverse population regardless of how long they have been in operation and whether or not they are co-located with another organization. The average percentage of minority clients is 43% for all centers in the sample. This is consistent with the July 2004 National Women's Business Council study, which estimated that 46% of all women's business center clients in 2003 were minorities (Richtermeyer and Fife-Samyn, 2004).

Women's business centers also serve a modestly educated population of clients. Almost half of clients have only a high school diploma (49%), with 6% having less than a high school education. Centers in nonurban areas report a slightly lower proportion of clients with at least a college degree (41%) than those in urban areas (47%). In general, the educational distribution of the clients served by the centers is consistent regardless of age, location, or whether or not the center is co-located, with an average of 55% of the clients having at most a high school degree. (Sample size dropped to 28 center responses for these demographic questions due to non-response or the lack of tracking of this information by the centers.)

Centers that could estimate income level of their clients report that two-thirds of clients served have a household income less than \$50,000, and nearly all clients (94%) have a household income less than \$100,000. This income distribution of clients was consistent for older and newer centers, as well as for co-located and stand-alone centers. However, centers located in nonurban areas report a significantly greater proportion of clients with a household income less than \$50,000 (90% vs. 57%,  $p < .05$ ). (Again, sample size dropped to 29 center respondents for these demographic questions due to non-response or the lack of tracking of this information by the centers. These income categories represent those given to the respondents on the survey.) Thus in general women's business centers serve a population that can be considered predominantly economically disadvantaged.

With each center reaching an average of just under 1,000 clients per year, the level of nascent entrepreneurship is high. According to the Global Entrepreneurship Monitor (GEM) 2003 report (Minniti and Bygrave, 2003), total nascent entrepreneurial activity among women in the United States is 8.2% of the adult population. On average, the

centers in this research reported that more than 60% of their clients were managing a start-up business and 66% of those were nascent entrepreneurs, managing a start-up that is less than three years old. In other words, approximately 40% of women's business center clients are nascent entrepreneurs compared with the general rate among U.S. women of 8.2%. The proportion of women's business center clients who owned a business was similar in both urban and nonurban areas and it was also similar regardless of age of the center, and whether or not it was co-located. The conclusion is clear: women's business centers succeed in their mission. They are drivers of nascent entrepreneurship among women who are socially and economically disadvantaged.

## **SHARED PRACTICES CREATE EFFECTIVENESS**

Women's business centers exhibit shared practices that underlie their success and constitute the source of their uniqueness. These shared practices address many of the situational and cultural barriers of the women clients they serve (Brush, 1997). First, centers tailor programming to be relevant to the industry interests and time schedules of women clients. Second, centers use a relationship-oriented approach to attract targeted clients and to create a safe environment based upon trust and connection. Finally, women's business centers focus on network building to create a bridge to business culture for clientele. Through this activity, women's business centers create a community of support that enhances the success of both programs and clients. Networking, mentoring, role-modeling and peer-to-peer roundtable discussions are key shared practices that support this objective. This section provides an overview of key research findings identified as shared practices forming the foundation of success for women's business centers nationwide.

### **Tailored Programming**

The main objective of women's business centers is to provide technical assistance and support to aspiring women entrepreneurs. Through tailored programming, women's business centers pay close attention to clients' interests and the reality of their lives, customizing programming to best suit the needs of women. Programming is offered across a range of topics and formats, covering both business functional topics, as well as support services. The most frequently attended formats are one-hour seminars followed by one-day workshops. Clients typically prefer the morning or noontime periods, as opposed to the afternoons or evenings for programs. Center directors report that the most frequently attended sessions are on business planning, finance, and marketing, while the least attended sessions cover employment/origination and equity financing.

In addition to functional business training, women's business centers offer clients the opportunity to explore and learn about an array of industries. The industries that clients expressed the greatest interest in are retail (96%); accommodations/food (90%); other services, including child care and pet care (90%); and arts, entertainment, and recreation (76%). Clients express the lowest level of interest in manufacturing and biotechnology.

Women's business centers also tailor educational programs in order to "meet clients where they are," particularly with respect to low-income minority women. The consensus among directors at the women's business centers in this study is that women

entrepreneurs who seek assistance through the centers have a dimension of needs that are specific to their experience. According to the directors, these women's distinct needs often reflect a lack of experience in the business world, an inability to secure funding and a disproportionate amount of childcare responsibility. Directors confirm that these needs are particularly evident among the low-income minority women their centers serve. Specifically, women usually shoulder more time-consuming family responsibilities as caregivers and have less access to credit and lower financial or business literacy. Also, many women clients view their businesses as a way to provide for and spend more time with their families. Finally, in their efforts to start businesses, women clients may experience role incongruity, putting social gender expectations as caregivers in conflict with business leadership expectations as entrepreneurs. This is often particularly apparent among women of more traditional gender-role ethnic culture backgrounds, such that they receive less family support for their business endeavors (Native American, Hispanic, Iranian, rural Caucasian, and Taiwanese women were mentioned). Directors also perceive that ethnic and racial minority women often experience less respect from business community members as well due to stereotyping (bankers, educators and administrators were specifically mentioned).

Given the realities and experiences of women clients, directors report that center clients are often more anxious about the prospect of starting a business. In response, center programming is tailored to address the personal as well as business development issues that clients face as they seek to start businesses. Some specific programs mentioned were "Workshop on the Mindset of Women Business Owners," "Life Skills Seminar on Empowerment," "Balancing Life and Family," and "Women's Networking and Empowerment Series." A final area of tailoring reflects the educational and English language level of center clients. Because many women's business center clients are recent immigrants, for whom English may be a new language, adjustments are made. In some cases, bilingual education is provided while in others curricula are designed around a secondary school educational level and teachers are trained to speak slowly and without American idioms. The distinct needs of women's business center clients constitute the situational barriers they experience as a result of social and economic disadvantage. Tailored programming can help break down some of these barriers.

### **Relationship Orientation**

A second shared practice among women's business centers is a relationship orientation manifest in one-on-one outreach, counseling and long-term connection with clients. This relationship orientation creates a supportive learning community and is an important aspect of the services provided by women's business centers. Through this approach, centers are seen by the women clients they serve as "safe spaces" for learning and the pursuit of their entrepreneurial goals. Programming that prioritizes content common to and valued by women, and that is delivered primarily by women staff, sends a strong signal to clients that women's business centers are a safe and accessible educational space for women.

Directors noted that some women clients seek the help of a women's business center to start a business because they are experiencing a financial or personal crisis, such as divorce or job loss. Others, as noted earlier, may do so to overcome the gender role

constraints of their home environments. The relationship-orientation combined with the high percentage of female staff members, encourages clients to confide in center professionals about their position in their family hierarchy and how it may curtail their financial independence. The relationship orientation itself then becomes a support service tailored to women.

A focus by centers on connection and relationships does not negate the pedagogical focus on serious accomplishment of entrepreneurial goals. Many directors commented that clients often seek out the refuge of a women's business center after trying to attend business training classes offered by other organizations. Center directors are sensitive to the needs of women, both in terms of situational barriers and learning style preferences. Many directors talked about their observation that women have different "learning styles" from men. One center director noted, "Women have different learning styles from men. We try to establish a personal connection with women. Women are often intimidated by men." Directors perceive that women value learning through relationships rather than learning in an impersonal way, and that women respond better when taught in a holistic manner instead of being taught specific skills in a piecemeal fashion. As women's business centers adapt to these needs, they are nonetheless firm in their focus on inspiring and training women to establish businesses. In the words of a director, "We like to say, we hold hands, we give you hugs, and we kick you in the butt."

Center directors are acutely aware of the gender-role, race and class-specific obstacles to starting a business which their client population faces. Women's business centers provide entrepreneurial education and support programs targeted specifically for women, and delivered with an approach designed to build trust and connection. This programmatic tailoring and relationship oriented philosophy are unique features to women's business centers.

### **Network of Connection**

A third shared practice identified among women's business centers is the use of high-touch support services to build a network of community, provide access to opportunities, spotlight aspirational role models, and build professional and personal development. Through this network of connection, centers provide a bridge to business culture for their clients.

Mentoring, role modeling and networking opportunities are among the most important of support services that centers provide to their clients. More than 80% of the centers provide networking, mentoring and peer-to-peer learning opportunities. Other important personal development support services provided include time-management and leadership training. Many focus group participants noted that women clients often report a sense of profound loneliness that center programs can help quell, by providing role models and a network. One director described the importance of networking for her clients, "[Starting a business] feels very daunting. Some of that is reduced by seeing women who look like themselves and women who have had the same experience succeed."

Often, women's business center clients have not had the opportunity to participate in the mainstream educational and economic environment. At the centers, aspiring women business owners have the opportunity to learn about business culture from successful women entrepreneurs. Networking opportunities provide a sense of camaraderie and emotional support among women, and serve as a primer for how to navigate in a business setting, how to make contacts, how to make an entrepreneurial pitch, and how to follow up on a connection. Directors underscored the importance of this networking as a bridge to the business community. One spoke about how women often do not know what type of business they would like to start, and how women have various and complementary skills, "Not every woman can by themselves create a business, but some of them together can. We can get them together. Women like to share their business ideas." Women's business centers serve as a locus of connection to potential business partners, entrepreneurial role models, and business community contacts for their clients.

Through the shared practices of tailored programming, relationship orientation and network building, women's business centers create a positive environment for socially and economically disadvantaged women to take advantage of technical assistance and support for building businesses. The approach to entrepreneurial education shared among women's business centers creates effective results with respect to the number of clients who are nascent entrepreneurs.

## **CHALLENGES AND OPPORTUNITIES**

Despite the effectiveness of women's business centers, specific challenges and opportunities present themselves. The top three challenges center directors perceived are securing funding, center infrastructure, and working with the Small Business Administration (SBA). These challenges are interconnected. Funding levels affect a center's ability to develop its infrastructure through additions to staff or technological capability. And, because SBA funding plays a major role in most women's business centers' operating budgets, working with the SBA is intimately connected to the funding challenge. These challenges can also be seen as opportunities. Specifically, women's business centers can extend and enhance the impact of their work by diversifying their sources of funding and creating stronger connections with both the Small Business Administration and with other like-minded community and business organizations. This section summarizes the research findings with respect to the challenges and opportunities facing women's business centers.

### **Funding**

As non-profits, women's business centers operate on lean budgets as well as with lean organizations. Annual budgets range from a low of \$25,000 to a maximum of \$3.1 million, with an average budget of approximately \$745,000 per year. Location does not have a significant impact on the average budget of the centers in our sample. Not surprisingly, centers that are co-located and centers that are less established have significantly lower budgets—most likely because both have smaller staffs, on average.

A high percent of the centers (87%) have at some point in time received grants from the SBA. SBA funding plays a major role in sustaining women's business centers, accounting for an average 42% of center funding, but other major funding sources include private sources including fee income (18%), bank loans (5%), public and private grant foundations (16%), and non-SBA government sources (14%).

Funding is the single greatest challenge to sustaining the success of women's business centers. Funding is the most common concern of center directors—more than 70% of the centers list it among their top three challenges. A series of perceptual questions on funding reveals that while few directors are satisfied with the current financial state of their centers the majority have a financial plan and believe they have the skills required to raise funds. And, while 73% of directors report optimism about growing support for women's enterprise, a comparable proportion senses a more difficult funding climate.

### **Infrastructure**

Funding and staffing are closely connected. Women's Business Centers operate with fairly lean organization structures. The typical center has an average of five full-time and two part-time employees. Leadership of the centers is reasonably stable, with the tenure of a center director averaging four years. In addition to this daily leadership, nearly 90% of the centers in our sample have a board of directors. Many directors report that they do not have enough time to raise funds and develop relationships with financial institutions. Often, staffing to pursue financing is tight due to the one-on-one relationship approach with clients emblematic of the women's business center approach. The structure of grants also presents challenges to programming and staffing. Further, since grants are often given on one-to-three-year cycles, center directors report that they face running out of funds for existing projects and the challenge of providing consistent services. Further, funding is often available only for *new* initiatives, and directors complain that they do not have enough staff to service current programs, let alone invest in new ones. Finally, since grant funding generally may not be used for operating costs, having the resources to adequately support staffing is often a challenge. As one director commented, "Federal government funding is most available, but has to be matched with state money—none of it is for operating costs. [We need money] so that people can do the work."

Since funding directly affects the staffing level a center can afford, it, in turn, produces other challenges that center directors mentioned: the ability of the centers to follow-up with clients, to reach out to low-income minority women, to secure attendance at classes, and the ability to train existing staff members, especially in the areas of technology and grant writing. A lack of staff or high staff turnover feeds into the challenge of establishing leadership and maintaining the women's business center culture at centers. The challenge of adequate infrastructure is acutely felt by women's business centers.

### **Collaboration with the U.S. Small Business Administration**

Strong collaboration with the Small Business Administration poses another major challenge for women's business centers. Just over half (55%) of directors expressed satisfaction with the financial support received from the SBA but barely one third (31%)

are satisfied with the SBA grant process. Enhancing the disparity in satisfaction with the SBA would be beneficial to women's business centers. When asked what improvements center directors would like to see in the relationship between their centers and the SBA, the overwhelming answer was better communication (54%). Center directors were not sure that the SBA fully understood the work actually being done by the centers and admitted that they did not always clearly understand the SBA's procedures. Many directors would like to see better direction from the SBA on procedures and guidelines and stronger lines of communication. Further, many directors voiced the impression that the SBA did not seem to care about the work that women's business centers do. One wrote, "I would like for the district direct to acknowledge and appreciate the efforts and accomplishments of our center," while another commented that she longed for "a sense that SBA cares if we live or die." Other major concerns about the SBA were the amount of paperwork they needed to fill out for SBA funding (14%), the amount of time it took for the SBA to provide reimbursements (12%), and the desire for more funding (10%).

Overall, funding, infrastructure needs, and connection to the SBA pose serious challenges to the daily operations of Women's Business Centers. Despite these constraints, centers succeed in providing effective outreach and entrepreneurial education to socially and economically disadvantaged women.

### **Opportunities**

Given the effectiveness of women's business centers, it is worthwhile considering the opportunities for extending and enhancing their work. The evidence from this study suggests several possibilities. The first, and perhaps greatest, opportunity for enhancing center effectiveness relates to increased funding. Since women's business centers have an established track record of creating nascent entrepreneurs among a population of socially and economically disadvantaged women, increased funding for existing as well as new centers would likely extend that success. A second opportunity is available through the diversification of funding sources. Funding is a critical issue for centers as they are largely dependent on outside funds rather than fee or programmatic income for their operating budgets. Funding has become increasingly difficult in recent years and the Small Business Administration is providing less than sufficient support for women's business centers. The funding environment is extremely challenging for center directors serving a clientele that continues to grow with each year and who lack equal alternatives to turn toward for assistance. In a challenging funding environment, any opportunity to further diversify and enhance sources of funding for a center should be seriously considered. Third, improvements to both federal and local organization connections may benefit women's business centers. Certainly a revised operating approach on the part of the SBA would be welcomed by center directors. But given the status quo, directors might prioritize emphasis on improving local relations with business and community leaders. Capitalizing on local connections might yield the dual benefits of enhancing client networking opportunities and augmenting center fundraising sources and levels.

## **CONCLUSION**

This study examined the accomplishments of women's business centers throughout the United States and found that women's business centers are drivers of nascent entrepreneurship among women. This track record can be seen in the following findings:

- Women's business centers consistently serve clients nationwide who are economically and socially disadvantaged. Two-thirds have household income below \$50,000, less than half have more than a high school education, and 42% are women of color.
- On average, 60% of women's business center clients are actively managing a business venture and two-thirds of these clients have businesses less than three years old. Overall, this indicates that approximately 40% of women's business center clients are nascent entrepreneurs, well above the rate of 8.2% among U.S. women.
- The success of women's business centers can be attributed to shared practices targeted specifically to women's situational needs. Programming tailored to women's interests and needs, a relationship-oriented approach, and networking activities that create a bridge to business culture are key practices consistently used by women's business centers nationwide.

Women's business centers serve an important role as unique providers of business formation education to women clients who are socially and economically disadvantaged. Increased funding and community support would enhance the impact of women's business centers and augment a powerful source of nascent entrepreneurship and economic development among disadvantaged women.

Marion O'Connor, Management Researcher, Irish Management Institute

### **ABSTRACT**

Adding to the existing body of research on the strategic development of Irish SMEs, this paper proposes a model for a management development programme (TRANSFORM) for developing the skills of owners and managers in SMEs. In addition, this paper details the transfer of learning back to the workplace that occurred when applying this model in a practical SME context. It also highlights the effectiveness of developing management teams as opposed to developing a group of individuals.

This paper charts the progress of 20 managers from nine Irish companies in the print, industrial product and construction products sectors who attended the first programme over a 15 month period. It tracks their individual progress and the evolution of their businesses by providing pre and post programme analyses. Questionnaires and focus groups were used to elicit programme participants' business and individual needs, their views on the programme and the personal and organisational impact. Almost a year after completing the programme a subsequent follow-up focus group was held with participants, the results of which form a central element in this paper, identifying the key outcomes of the programme for SME businesses and managers.

In addition, this paper details the background, rationale, structure and content for the proposed model for a management development programme for SMEs and more importantly highlights the key benefits which the programme offered SME owners and managers in providing an effective and strategic approach to the management of their businesses. The findings are of potential interest to those involved in management development for SMEs.

### **INTRODUCTION**

In the context of rapid environment and industrial change in a landscape which is experiencing increased competition e.g. from low cost eastern economies, it is recognised that there is an increasing need for the development of strategic thinking and change leadership skills in SMEs. It is imperative that managers can generate strategic options for survival and growth. As a result, a model development programme structure –TRANSFORM - was created and refined through practice-oriented feedback.

#### **Background**

Before discussing the details of the TRANSFORM programme<sup>i</sup> and its impact on SMEs, it is important to outline the environment and standing of SMEs in Ireland. Since the foundation of the Irish Government, SME growth in Ireland has been moderate. The vast majority of businesses in Ireland are small and medium sized enterprises.<sup>ii</sup> These businesses employ over 80% of the workforce and make up at least 95% of all trading entities. In terms of sectoral

composition, the majority of businesses are engaged in service activities (O'Driscoll, 2004). Irish SMEs have traditionally struggled to gain a foothold in Irish industrial policy – economic objectives have been traditionally designed to attract foreign-owned industry. SMEs have therefore had to struggle to find sources of competitive advantage which would aid their survival in the increasingly changing competitive landscape. The issue is compounded by the fact that Ireland is a small and open economy on the periphery of Europe.

In 2004 the Irish Government appointed an Enterprise Strategy Group to prepare an enterprise strategy for growth and employment in Ireland up to the year 2015. They concluded that Ireland's industrial policy was in need of new strategic direction as Ireland moves from being an investment or production-based model to one that is market and knowledge-based. The Group highlighted the importance of developing indigenous Irish industry and enhancing management capability. Management capability was viewed as an essential condition which must exist in order to create sustainable indigenous enterprises (O'Driscoll, 2004). Therefore, the development of SME managers in Ireland is of enormous national importance.

Historically two government agencies, in particular, have helped to foster SME growth and development - Enterprise Ireland was founded in 1992 to grow Ireland's indigenous industry while FÁS, the national Training and Employment agency was founded in 1988. The Irish Management Institute, Ireland's national management development centre, has been instrumental in the development of SME owners and managers since 1952.

### **Structure and Size of SMEs**

The following European Union classifications (2005) of organisations by size currently exist in Ireland:

- Micro-businesses are those that employ less than 10 with a turnover of less than €2 millions
- Small businesses are those that employ between 10 and 50 people with a turnover of up to €10millions (formerly €7 millions)
- Medium-sized businesses are those that employ between 51 and 250 people with a turnover of up to €50m (formerly €40 millions)
- Large businesses are those that employ more than 250 people and have a turnover greater than €50millions. (formerly €40 millions)

### **Identifying the Need for Developing SME Owners and Managers**

Enterprise Ireland, the state agency with primary responsibility for the development of Irish-owned businesses in manufacturing and internationally-traded services, in consultation with their mid-size indigenous client base, recognised an ever increasing need for the development of strategic thinking and change leadership skills. This need emerged from sectoral reviews and awareness of the need to improve the competitiveness of Irish enterprise. A Print forum was formed in 2002 which prompted print business owners to address these needs in the Irish traditional paper, print and packaging industry. The Irish Management Institute, Ireland's national management development centre, therefore developed 'TRANSFORM', a strategic planning and change management programme to help develop the skills of managers and owners in SMEs. A focus on managers ability to manage the process of change within their companies and to generate options for survival and growth was critical to companies in this industry.

A group of 20 managers from 9 companies in the print, packaging and industrial product sectors formed the pilot programme participants. Sectorally the breakdown was 7 Print and packaging and 2 Industrial product companies. Three companies were in the Small category while the remainder were Medium size as per the 1996 EU classification. The companies average sales were €10 millions with an average employment of 111. While average net profitability was 7%, four companies described their profitability as breakeven. 30% of combined sales were exported.

## METHODOLOGY

A four-step approach was adopted in testing the TRANSFORM model for SME management development. It is important to note that the original TRANSFORM model was developed from extensive feedback from industry bodies, SMEs and State developmental agencies who identified a need for SMEs to employ structured strategy development processes during times of change. In order to test the model, a total of 4 questionnaires, as outlined below, were designed and administered at various stages of the programme delivery. An average response rate of over 80% was achieved.

### Research Stage 1

**Pre-Programme Business and Personal Needs Analysis:** Programme participants were asked to identify their business and personal needs – a questionnaire template was completed prior to commencing the programme.<sup>iii</sup>

### Research Stage 2

**Midyear-Evaluation:** Participants were asked to comment on the progress of the programme - a questionnaire was administered 'halfway' through the programme after 5 modules were completed.<sup>iv</sup>

### Research Stage 3

**End of Programme Evaluation:** After completing the programme, participants were asked to evaluate the programme on a number of criteria, including programme content, personal and business benefits, delivery and impact. This questionnaire was administered by an external consultant.

### Research Stage 4

**Post Programme Follow-up:** This stage consisted of two elements:

- Questionnaires which were completed by participants approximately 1 year after the programme concluded.
- Focus group also held 1 year after the programme concluded.

Questionnaire findings were complemented by the 'follow-up' focus group discussion which was held with participants. Participants were asked to discuss the progress of their companies since completing the programme and to explain whether any learning gained was actually transferred back to the workplace – the personal and business outcomes of the programme. Rich qualitative and quantitative data were captured from managers who identified the key personal and business benefits of the programme. A mid-year focus group was also held with participants of a subsequent programme to ascertain their views on how the programme was progressing.

In relation to sampling, this was not an issue in this study due to the fact that it was possible to study the whole population i.e. all participants on the programme.

## THE TRANSFORM MODEL

The model (see Figure 1) adopts a four-phased approach to development:

- (1) Identify needs
- (2) Develop strategy
- (3) Action
- (4) Review.<sup>v</sup>

---

**Figure 1 here**

---

### **(1) Identify needs**

The business and personal needs of the participating companies and individual managers were identified prior to commencing the programme through a pre-programme company visit and interview and the completion of self training needs questionnaires.

### **(2) Develop strategy**

A key focus for the programme was the development of a 5 year vision and strategy for each business. Workshops supported the generation of such a strategy. Businesses were required to devise a strategy and document this in the form of written strategic plan.

### **(3) Action**

The purpose of the action phase was to implement strategy and to manage the necessary change. In practice the action and review became a feedback loop with review informing further action. Businesses were required to implement learning from workshops consistent with their strategic direction.

### **(4) Review**

Reviews at workshops informed strategy and action and the process was iterative.

Key outcomes are identified after each phase including devising an impact statement, constructing a strategic plan and identifying results. The programme has a duration of one year and comprises residential workshops, overseas visits and business counselling. Recognising the time pressures that SMEs experience, two-day residential workshops are scheduled at monthly intervals for 1 year. Each of the workshops contains a mixture of subject matter integrated to optimise and support action learning across disciplines. The programme content includes modules on the following topics: strategic planning and growth, change management, export marketing and funding a marketing plan, financial dynamics, creativity and innovation, new product development, managing operations, resources and information, leadership and team building, personal effectiveness, communication skills and cultural awareness.

As part of the programme each business is given one-to-one support through business counselling. Following residential workshops companies receive a visit from their business counsellor who worked with the management team in progressing their strategic planning process. This facilitates a customised approach for each company, helping them to:

- objectively audit their business and their potential to expand
- guide managers in change and decision making for the growth of their business
- facilitate the application of learning from the workshops to on-the-job behaviours

Emphasis is placed in the programme on providing networking opportunities in addition to an action learning approach. The process is facilitated through a combination of the following: interactive workshops, relevant case studies, business related work programme assignments and exercises (particularly the development of a five year strategic plan for the business), experience of other participants, business counsellors, network dinners, expert panel presentations, discussion groups and overseas visits. The model was viewed as being iterative in nature with the review of proposals and strategic plans being part of a continuous process.

## FINDINGS

The overall findings from the study point to the positive impact of the TRANSFORM programme as a management development model for SME managers and owners. This section focuses on findings from the various stages of the study – from the pre-programme analysis, end of programme analysis to the follow-up study.

### **Research Stage 1: Pre-Programme Business and Personal Needs Analysis**

With regard to the pre-programme questionnaire, participants pinpointed potential future developments in their companies and identified the role of TRANSFORM in helping them to achieve their goals. The major challenges or ‘blockages’ identified by managers in their organisations in moving forward, included the following: marketplace challenges including the economy and increased competition, lack of international marketing/selling skills, financial issues (high gearing, cost base, low margins, cash flow), risk adversity, lack of salespeople, employee issues, time management issues, lack of an ability to change, absence of leadership ability and a low level of management capability.

In relation to how managers viewed their businesses moving forward or the improvements they desired, among the many goals mentioned included: the need to reduce costs, increase growth, improve systems, increase product development, divest some business units, increase research and adopt a more proactive approach to management. In addition, participants identified specific personal learning needs which included leadership, assertiveness, strategic thinking, communication skills, teambuilding, finance and people skills.

### **Research Stage 2: Midyear Evaluation**

For the purposes of this paper the midyear evaluation completed by the first group of programme participants is not referred to. The results from the mid-evaluation of the second programme group are referred to briefly at the end of the paper.

### **Research Stage 3: End of Programme Evaluation**

After completing the programme, participants completed an evaluation questionnaire. The overall results were very positive – over half of participants rated the course as being ‘excellent’ (55%) while the remainder (45%) rated it as being ‘very good’. In relation to the *impact of the programme on their business* over the period that they attended the programme, the majority of participants stated that the company had either changed ‘quite a lot’, or changed ‘somewhat’. In relation to the future impact of the programme, 25% of participants surmised that it would have a ‘great deal’ of impact, 50% stated ‘quite a lot’ while the remaining 25% stated ‘some’.<sup>vi</sup> As highlighted by one participant ‘*I am now able to look beyond our current business and assess the impact of new products or customers and identify the strengths and weaknesses within our business. I have a better understanding of the financial side of the business.*’

In relation to the *personal benefits* gained from attending the programme, the majority of participants stated that they had either changed ‘quite a lot’ or ‘somewhat’ after attending the programme, as stated by one participant *‘I am much more confident in my approach to change and feel stronger as a manager. I believe more than ever that my ability to help people change and develop has been increased enormously (new programmes are already implemented and are starting to show results). I have a better understanding of how to formulate a plan and how to get others to buy in. I can see the bigger picture than before.’*

#### **Research Stage 4: Post Programme Follow-up**

Almost a year after the first programme concluded participants (**9 out of 20**) attended a focus group discussion and completed the follow-up questionnaire. The participants shared the key business and personal outcomes that they had experienced and witnessed from attending the programme.

- **Business Impact**

Participants were of the view that their respective organisations had changed as a result of the programme – rating on a five-point likert scale with 1 being ‘no change’ and 5 being ‘a lot of change’, 22% of participants gave a rating of 5, 33% a rating of 4 and 45% a rating of 3. The business impact of the programme are listed in Table 1.

---

**Take in Table 1**

---

- **Personal Impact**

All participants who attended the focus group were of the view that they had changed personally as a result of completing the programme – rating on a five-point likert scale with 1 being ‘no change’ and 5 being ‘a lot of change’, 22% of participants gave a rating of 5, 33% a rating of 4 and 45% a rating of 3. The key personal benefits from attending the programme are listed in Table 2.

---

**Take in Table 2**

---

The progression of the programme from the identification of business and training needs to the business and personal impacts of the programme is charted in Appendix A.

## **DISCUSSION**

From the analysis of data it can be observed that a positive business and personal impact of the programme on 9 SMEs (20 participants) occurred. A number of key points are worthy of further discussion.

#### **Developing a structured approach to strategy development**

Participants consistently identified key organisational benefits which the programme delivered, complimenting the overall ‘structured approach to strategy development’ that the programme promoted. They spoke highly of the ‘common direction to strategy’ and the ‘clear vision and goals focus’ which were being achieved in their organisations through the knowledge gained on the programme.

### **Learning as a management team**

A key benefit that was described was the management team-building aspect of the programme – some participants mentioned that the real benefits from the programme were being attained due to the participation of the management team as opposed to individuals. They mentioned that their organisations were devoting more time to strategic issues and appreciated the fact that the programme was forcing them to set deadlines for implementation. A number of organisations highlighted the human resource changes they implemented since commencing the programme, including the introduction of a performance management system etc.

### **Enhancing Skills**

On a personal impact level, participants valued the variety of management techniques learned on the programme which they were applying in their organisations. They increased their communication, listening and planning skills. Management and leadership modules were also valued.

### **Adopting a broader perspective**

Some participants mentioned the fact that they enhanced their ability to focus on strategic issues as opposed to issues of an operational nature. They were learning to view the organisation from a different perspective – ‘as a shareholder as opposed to an operator’. The programme provided participants with an ability to ‘see the wood from the trees’ and ‘think outside of the box’. This move from a ‘silo approach’ is encapsulated in the comment from a participant *‘I feel my outlook towards the business has changed considerably. I tended to confine myself to my designated role within the company. Now I feel I can relate to other areas of the business much more readily.’*

### **Learning from others**

Participants valued sharing experiences with other organisations in the group stating that it was beneficial to speak with other organisations experiencing similar challenges. Keynote speakers were complimented for sharing their experiences of change and how they managed to transform and adapt.

### **Transferring learning back to the workplace**

Participants complimented the knowledge content of the programme and were able to relate these modules back to the workplace e.g. finance and economics.

## **CASE STUDIES**

Examples of the impact of the programme on 4 sample companies are provided below.

### **Company A – Print packaging**

Before the programme Company A had a turnover of €10m and had breakeven profitability. Now the company reports turnover for its new products which it exports globally has grown 39%. Net profit has increased to 2 %.

#### **Outcomes**

- Increased sales globally - opened up markets in Denmark, Finland and Sweden and currently trying to enter the Croatian, German and the Benelux markets.
- Sold intellectual property to Australia, New Zealand and Africa
- Company is more focused on innovation and prepared for ongoing change
- Production / manufacturing processing time is down from 8.5days to 6.5 days

### **Company B - Print**

The print industry in Ireland has been experiencing increased changes and is in turmoil, with significant players dropping out. Company B completed a merger since the programme concluded. It consolidated operations to one location and achieved savings in labour and running costs. It successfully merged cultures through a single management team and constant communications. It commenced the merger process with trade unions and experienced no industrial relations issues.

#### **Outcomes:**

- Doubled market share
- Exceeded growth targets
- Doubled product sales
- 40% higher turnover
- Divested non-core activities

### **Company C – Industrial Products**

Before the programme commenced the company had sales of €4m and breakeven profitability. One year after completing the programme it had targeted sales of €6.5m and net profit of 7% was on track. One of the company's managers stated *'The company culture has changed to one of employee involvement throughout the organisation with planning at the forefront of everything we do'*.

Some of the initiatives implemented included the following:

- Appointed non executive director
- 'Pruned' and re-structured management team
- Established operation in London
- Increased employment by 50% (from 60 to 90)
- Has scheduled the establishment of a manufacturing site in Poland for Q1 2006.

Looking to the future the company is very positive *'We are well on the road to being a top class organisation with clear direction that is understood by everyone. The organisation no longer relies on the MD [Managing Director] for everything which was a substantial problem in the past.'*

### **Company D - Industrial Products**

The company increased productivity by 20% as a result of the introduction of new equipment. The justification for purchasing new equipment was made easier by the company being capable of applying the strategic plan developed during the programme. Financial justification was possible because of the training received through the programme and an improved ability to forecast results.

#### **Outcomes**

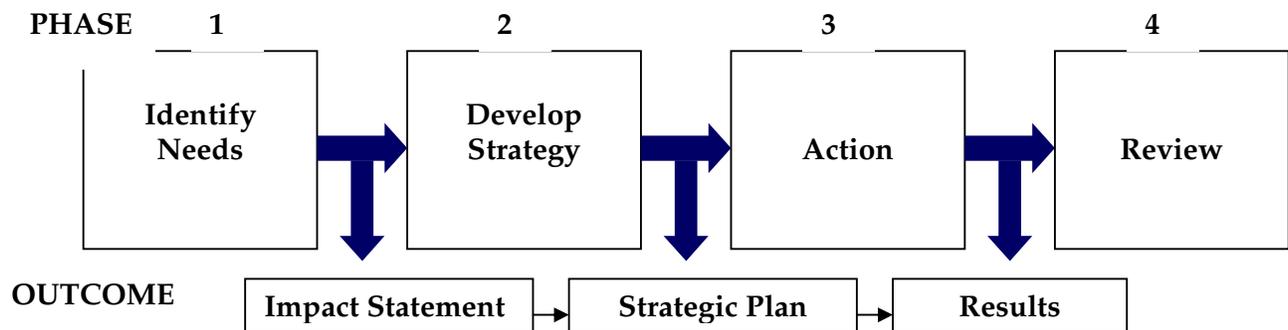

- 2004 was best financial year ever
- 20% increase in productivity
- Employee level remained constant
- Increased employee morale
- Sales and marketing - managed to get a 'top 5' customer (as identified in 5 year plan)
- Investment in IT and refurbishment of buildings to enhance customer image and profile

## **CONCLUSION**

This paper has detailed the background, rationale, structure, content and delivery for the proposed model for a management development programme for SMEs. It highlighted the key benefits which the programme offered SME owners and managers in providing an effective and strategic approach to the management of their businesses. The programme has aided managers in adopting a broader and more strategic focus to managing their companies, resulting in the transformation of their business models. Programme participants also experienced the key benefits that arise from learning as a management team. After completing the programme, it was remarkable to observe that companies operating in traditional industries which had become stagnant were beginning to experience growth rates associated with more vibrant industries. In addition, the programme helped managers to accept the need for change in their organisations, emphasizing the importance of adopting a structured approach to strategy development. It has taught managers to welcome change as opposed to shunning it, as stated by one participant *‘The programme reduced my personal fear of change. I believe the whole programme stimulated me personally and offered new avenues of thought for me. I am having great success in promoting the need for change throughout the organisation and I now have a cohesive management team working in harmony with each other who are committed to change. We are on the road to being a top class organisation with clear direction that is understood by everyone.’*

### EPILOGUE - AN EVOLVING PROCESS

A *second* TRANSFORM programme is in progress with 22 participants from 7 companies. Participants are following a revised programme model which focuses on early production of strategic plans and implementation of change in an action learning model. After completing five modules the majority of participants have already reported that they have experienced some personal benefits from attending the programme. In relation to the realisation of *immediate* business benefits to their companies, 89% of participants were of the view that these benefits had been ‘partly or fully realised’. Only 11% of participants believed that they had not been realised.

**Figure 1 TRANSFORM Programme Structure**

Extended Abstract

The purpose of this pilot study is to research the stages of technology transfer – and related literature on the environment for corporate entrepreneurship – as they might best be applied to the public universities in a smaller state with a Federal lab. The general research question is whether or not the critical institutions of the State of Idaho have developed the entrepreneurial climate and the processes required to stimulate the technology transfer proposed in the State’s science and technology plan.

To examine the technology transfer process, as it exists today, the authors devised a survey instrument based on a technology commercialization model created for the Department of Energy by Randall Goldschmitt. Phases, stages, and steps organize the model. The survey incorporates measures of perceived entrepreneurial climate as well as items asking respondent to rate their resources, research activities, incentives, and the leadership in their units. Many of the items take the form of open-ended questions.

The survey was administered - by email and in person – to a small sample of faculty in defined research areas at the three institutions of higher learning in the State of Idaho: the University of Idaho, Boise State University, and Idaho State University; and to staff at the Idaho National Laboratory (INL). Qualitative results reveal first that some faculty members do not identify technology transfer as an integral part of their research efforts. Second, some faculty members have a strong interest in taking part (with their research inventions) in the process, but lack the understanding and the administrative support to enter the process. Third, only a very few, mostly with experience outside Idaho institutions, have actively engaged in the process of technology transfer at their institutions. In this pilot study, those few are located at INL and the University of Idaho. Fourth, those faculty and laboratory staff members with strong interest have

been, in this small sample, newer faculty in engineering and biotechnology-related disciplines or research areas where an environment has encouraged participation.

In general, the pilot study pointed out more weaknesses than strengths with the process of technology transfer, as it exists today. A follow-up study will be aimed at clarifying the results, measuring them more precisely, and making process recommendations to stimulate technology transfer in the State of Idaho.

**Abstract:** There are strong pressures on small and medium enterprises (SMEs) to embrace a new *knowledge economy*. Information and communication technologies (ICT) are impacting on virtually all SMEs. However, local development and policy reports reveal a picture of poor management and lack of ICT skills prevailing among many SMEs. There are a growing number of policy initiatives, at regional, national and EU levels, to improve innovation and management capabilities among SMEs and to increase innovation and the development and sharing of knowledge within SMEs through encouraging lifelong learning. Yet, SME participation is very low, particularly among the microfirms with fewer than 10 employees. The most common reasons given by SME owners include lack of time, inconvenience and low relevance but lack of skills and knowledge have been identified as endemic by the national Learning and Skills Development Agency (LSDA). This suggests a lack of ‘absorptive capacity’ – having the prior knowledge and the ability to assimilate new knowledge and to share it effectively within the firm – may better explain low SME participation and high failure rates. Over the past 20 years, OUBS-based Small Enterprise Research Team (SERT) has been engaged in a number of longitudinal and cross-sectional surveys of management development, use of ICT and knowledge management in SMEs. Drawing on the findings from these regular surveys this paper examines SME learning needs, educational and development levels, and the effects of increased ICT-adoption on the acquisition of knowledge necessary for survival, growth and success in the new economy

## INTRODUCTION

There is tremendous pressure at UK and European Union (EU) level to encourage greater participation in the information society by small and medium enterprises (SMEs). The participation of SMEs (in Europe this refers to firms with fewer than 250 employees) is seen as crucial not only because of the size of the sector (99 per cent of Britain's 4 million firms and 55 per cent of its 25 million workforce) but also because of the role that SMEs can play in innovation and in promoting the diffusion of new technologies. The capacity of small entrepreneurial firms to make effective use of technology transfer, research and development, networking, and knowledge sharing are now recognised by policy makers and strongly supported. This is reflected at policy level in pushing the role that SMEs can play in innovation, in improving the functioning and competitiveness of supply chains and in the wider adoption of e-commerce. Two main related policy drivers are:

- increasing EU competitiveness in the face of global competition (especially from the US and east Asia);
- boosting sustainable local development in order to reduce social exclusion and to build a knowledge economy in Europe.

Although global competition and knowledge management tend to be the province of large national firms and multinational corporations, the business effects impact on SMEs. As well as facing tougher resource constraints in marketing their products abroad, SMEs face tougher competition for necessary competences and skills in local labour markets due partly to a poor supply of such skills and partly to intensified competition from larger firms. In its 2002 report on work-based learning in SMEs, Britain's Learning Skills Development Agency (Hughes et al, 2002) has identified a number of critical skills shortages among SMEs, summarised the policy challenges as:

'In a fast-changing world of work, the ability to adapt and develop new learning and skills is a crucial ingredient in a successful economy. Globalisation and the knowledge-driven economy require the UK to develop a more highly-skilled workforce in order to compete within high-value-added sectors of the world economy,' (page, 14)

In spite of the strong pressures, however, the report also acknowledged that SME participation is very poor and that most staff training and development (including that of the owners and managers) is informal. The average knowledge base in the SME sector, especially among microfirms, is low compared with larger organisations. The report concluded that workforce learning is very important in developing knowledge in the firm necessary to its survival and growth but that 'there are other ways in which the workforce may be developed and a wide range of methods may be used.' Increased use and commercial applications by SMEs of more advanced information and communication technologies (ICT) and related services are seen by policymakers as the key to improved competitiveness and a knowledge economy. There is little doubt that the increased diffusion of ICT applications and pressures from global competition are already having an effect on capabilities required for managing a successful SME. For instance, Freel (1999) identified the major skills gaps that impede successful innovation in SMEs as:

- technical skills in the workforce;
- managerial competency;
- poor marketing skills.

The focus of this paper is on the effects of these knowledge, capabilities and skills gaps in relation to SME growth and their effective participation in the emerging knowledge economy.

## ABSORPTIVE CAPACITY

Some 15 years ago, Cohen and Levinthal (1990) identified the problems suffered by firms with capabilities and knowledge gaps in effectively managing inwards technology transfer and R&D programmes. In their words, an organisation 'needs prior related knowledge to assimilate and use new knowledge'. They termed this the firm's 'absorptive capacity', a concept that has subsequently been broadened to include a firm's overall capacity for learning, implementing new knowledge, disseminating new knowledge internally and making use of new resources, including new technologies. Absorptive capacity is a function of the organisation's existing resources, existing tacit and explicit knowledge, internal routines, management competences and culture. In entrepreneurial SMEs, it is likely that this will be largely reflected the development, experience and motivation of the owner/manager and key staff members. Zahra and George (2002) further developed the concept of absorptive capacity to include the organisational routines and processes by which firms operate and manage knowledge. They identified four distinct areas where knowledge needed to be managed in successful firms:

- Acquisition;
- Assimilation;
- Transformation;
- Exploitation..

Acquisition and assimilation of knowledge were seen as *potential* absorptive capacity while transformation and exploitation of knowledge represent *realized* absorptive capacity ( Zahra and George, 2003). Liao et al, (2003) conclude that SMEs with higher levels of absorptive capacity would tend to be more proactive whilst those with modest absorptive capacity will tend to be more reactive and that 'reactive and proactive modes of SMEs' behavior should remain rather stable over time'. Another distinction, which is very relevant to SMEs, is that absorptive capacity involves external knowledge acquisition and internal knowledge dissemination within the firm (Heeley, 1997). According to Liao et al, (2003), 'potential absorptive capacity has received disproportionately less empirical scrutiny when compared to realized absorptive capacity'. This means that less attention has been paid to how firms acquire and use external knowledge and this where SMEs seem to be at a disadvantage and is a focus of this paper. Thus the management of knowledge acquisition and use is crucial. With respect to SMEs, the focus is on two main crucial areas of knowledge –

- the functional areas of the business, which relate to the people in the firm;
- strategy and the need to remain competitive, or at least viable, which relate to the firm itself as an organisation.

The degree of functional knowledge in a firm is related to the level and relevance of formal training, experience and the response by firms to their perceived need for capability in the functional areas. In turn, this seems to be related to levels of education, source of knowledge acquisition (college, university, consultant, etc.) and experience. In Britain, some 16 per cent of the workforce are university graduates but the proportion is higher among younger SME owners and those in manufacturing and business services (which includes consultants and the professions). On the firm related knowledge, earlier work on organisational learning (Argyris and Schoen, 1978) has re-emerged in concepts such as the learning organisation (Senge, 1990) and knowledge management (Amidon and Skyrme, 1997). Essentially, the model is one based upon knowledge sharing and, through constant and open communication, the making explicit of often buried or tacit knowledge held by all employees. The drawing together of experiential knowledge of key employees (including the owner/manager) and the making explicit the effective routines developed within the firm in order to share, combine knowledge and create new knowledge is the innovative process that lies at the heart of

knowledge management. Zahra and George (2003) view such routines as a prime element of absorptive capacity..

The acquisition of new knowledge raises issues concerning the source of information, the internal absorptive capacity for interpreting and absorbing the new information as applicable knowledge and the use of the new knowledge. The third area, the creation of new knowledge, raises issues concerning innovation, creativity, and strategy. In all areas, ICT is increasingly seen as providing support for these processes internally and in relations externally with other firms. The development of ICT-mediated formal and informal links between SMEs and the growth of virtual clusters or industrial districts fits the knowledge management approach. In its final report, the UK National Skills Task Force (2000) saw networks and clusters as the way for SMEs to overcome their skills and knowledge gaps. It recommended the 'development of new sectoral and local learning networks to support the training and development needs of clusters of small and medium sized businesses'.

Although there are few direct studies on knowledge management and SMEs, a 1995 survey conducted by OUBS among some 2,500 SME owners revealed that growth-oriented owners were more likely to be participative in their management styles and more likely to network (Gray, 1998). During 2001-2002, OUBS led an in-depth cross European study of SME networking and the effects of ICT on existing networks. The study confirmed that most SMEs belong to at least one network and that the main drivers are the exchange of business and technical knowledge, as well as social interactions ( Gray, 2003 ). Later OUBS research, as part of a pan-European study into the determinants of management development, revealed high growth entrepreneurial firms to be more systematic and strategic in their management development policies, including having higher commitment to development from the top of the firm (Thomson and Gray, 1999; Thomson et al, 2001; Gray, 2004). However, SMEs were found to engage in fewer management development activities than larger firms. Managers in SMEs are much less likely to have formal appraisals or discussions on their training needs (41 per cent of SMEs reported no appraisal system compared with 27 per cent of large firms). These systems are clearly an important part in building absorptive capacity and were largely absent in non-growth SMEs. However, it appears that a strategic orientation towards growth is a much stronger determinant than size of firm of the proactive development of absorptive capacity. Table 1 summarizes the mean score differences on formal management development activities (5-point Likert scales, with 1 representing little or no activity and 5 very frequent activity).

---

Table 1 about here

---

Large firms provide a lot more management development than SMEs and the development of competences, an essential element of absorptive capacity, is more often linked to the firm's strategy. Interestingly, the preferred method by the entrepreneurial growth firms involved the introduction of knowledge from outside the firm in the form of external courses and having an internal culture that makes more use of mentoring. However, most evidence suggests that the managers of Britain's smallest firms are resistant not only to training but also to other forms of wider participation. The human resource practices in many SMEs are not conducive to the creation and exchange of knowledge. This is also an area where the increased connectivity of ICT might be expected to help. Increasingly, the Internet helps SMEs to participate in useful networks or to pursue commercial and industrial linkages without a

strong need for spatial proximity. In general, ICT adoption and use appears to be related to the size of the firm, with larger and growth SMEs using far more ICT applications and functions than other firms (Eursostat, 2001; Gray, 2003). This suggests that absorptive capacity is also strongly linked to access to resources inside the firm (which appears to be one of the main effects of size). The key role played by ICT in the management of knowledge in SMEs was specifically addressed by Corso and colleagues (2003) who state that ICT applications can ‘play a key role in this process. By providing quick and easy access to external sources of knowledge and new and more intense communication channels with partner organizations, ICT can erase traditional constraints on SMEs innovation ability, while leveraging their flexibility and responsiveness.’ This paper now examines the characteristics of the smaller firms that also adopt similar approaches.

## **METHODOLOGY**

The findings reported below are from national UK surveys were conducted by the independent non-profit Small Enterprise Research Team (SERT), which is based at OUBS and has been conducting, publishing and disseminating research on SMEs regularly for the past 20 years. Drawing on the findings from recent SERT national surveys on ICT adoption and use (final quarter of 2003; 687 respondents); business objectives, personal motivations, growth orientation and innovation (first quarter of 2004; 808 respondents) and on educational levels of owners plus training and development (second quarter of 2004; 739 respondents) , this paper examines the effects of high and low absorptive capacity on actual growth over time among some 2,000 UK SMEs. The samples were drawn from a wider SERT database which has been recruited and periodically replenished through a random selection of firms nationally (with findings in SERT’s regular reports weighted to reflect the distribution of SMEs across industries in the UK). Because of an overlap of common respondents, it was possible to analyse responses across surveys. The paper uses these surveys to explore whether high absorptive capacity are more proactive in innovation and more entrepreneurial.

## **FINDINGS**

First, it is important to establish key differences between entrepreneurial and non-entrepreneurial SMEs. Generally, the strongest motivation among SME owners for managing their own business is to be independent but entrepreneurial SMEs tend to be more business-oriented and set themselves financial goals (Gray, 1998). SERT surveys confirm this picture as a stable feature of SME motivation as Table 2 shows.

---

Table 2 about here

---

The need for independence motive dominates. Further analysis of all the SERT surveys reveals strong age and size effects with the older SME owners of the microfirms feeling this need particularly strongly and the self-employed microfirm owners even more. In contrast, younger SME owners seem less concerned about the need to preserve independence which implies a stronger propensity to work with other firms. This has enormous implications for the absorptive capacity of those firms and attitudes towards innovation and networking. The most determining feature of entrepreneurial SMEs is a stronger desire than most SMEs to grow and compete Table 3 summarises these broad trends from 1991 to 2004.

---

Table 3 about here

---

The effects of prevailing endogenous economic conditions are clear. During 1991 the British economy was still in recession but by 1995 it was peaking in a boom. This serves to highlight the uncertainty under which most SMEs operate. It is this uncertainty that is often the biggest barrier to SME participation in networks and longer term collaborative ventures that could boost their absorptive capacity. There is, however, less uncertainty among the growth-oriented entrepreneurial SMEs where strategic intent does lead to actual growth. Each survey asks respondents to indicate whether sales over the past year have been up, down or remained at the same levels and, similarly, their expectation for sales in the coming quarter. In this case the reporting period covers two quarters which enable respondents to be classified according to whether their sales and expectations were consistently positive (high growers) through to those who were consistently negative (strugglers), with three intermediate categories. The growth-orientation variable is split between the growth-oriented who are keen to grow (some to a target, others indefinitely). Those who have a strategy to sell or merge their firm and the non-growers who report having no growth strategy or a desire to reduce the size of the firm. Table 4 is a cross-tabulation of growth orientation with the constructed measure of growth that spans some 18 months.

---

Table 4 about here

---

It is clear that growth intention is related to performance. Some 45 per cent of proactive growth-oriented SME owners reported consistent or variable growth compared with just 27 per cent of the reactive or static non-growth strategy firms. Perhaps more significantly, nearly three-quarters of SMEs without growth objectives are weak, struggling or static. In this context, it seems reasonable to conclude that they have very low absorptive capacity which appears to be more related to educational levels and learning capabilities rather than to resource factors such as a lack of technology *per se*. Regular surveys conducted by SERT over time reveal that only a handful of microfirms report that they do not own or use a computer. The patterns of ICT adoption by SMEs in Britain are shown in Table 5, which is based on the findings of the SERT quarterly surveys conducted over the past 20 years.

---

Table 5 about here

---

There has been a steady increase in the use of computers by SMEs, reaching effective saturation. However, the more proactive SMEs demonstrate their higher absorptive capacity in moving on from stand alone computers to internal and external networks that facilitate the exchange of knowledge. The penetration the Internet and the use of websites is expanding rapidly though there are still important firm-size differences. Microfirms are far less likely to

network their computers and or to adopt broadband but both these rates are up significantly since 2001 and look set to increase. Thus, most SMEs already have, or will soon have, the right infrastructure to support knowledge acquisition online. Whatever barriers there are to potential absorptive capacity among SMEs, they are likely to be due to factors other than technical. It may be that background levels of educational attainment of SME owners are important influences on a firm's absorptive capacity. In 2004, SERT surveyed 739 SMEs on their highest formal qualifications. There was a strong recognition of their own development needs by SME owners and owners with degrees or professional qualifications were much more likely to provide staff development than those with only school or no qualifications. With respect to their functional areas of knowledge need, ICT and marketing dominate overall with finance in third place. First degree graduates had a stronger preference for marketing skills, which is quite entrepreneurial. SME owners with technical qualifications, in comparison with holders of all other qualifications, did not have such a strong need for developing more effective use of ICT (this group would include those with ICT-related qualifications) but they do feel a need to improve their marketing and financial management skills. It is interesting that people who only have school-level qualifications were more likely to report that they have no development needs. This suggests that there may be a lack of awareness among less qualified people on their knowledge gaps. This lack of awareness, plus the wide lack of ICT skills, poses real barriers to the development of knowledge from external sources and through sharing with peers. In a very real sense, this low absorptive capacity appears to be linked to low learning abilities and to impede SMEs in shifting from reactive to proactive strategies and behaviours.

A key element of absorptive capacity is the propensity to innovate. Based on a frequency count of the number of different areas of innovation they mentioned, respondents were classified into two categories, single activity and multi-activity innovators. There was a larger category of those who reported doing no innovation at all. Multi-activity innovators were significantly more likely to be consistent growers than single-activity innovators who in turn were more likely to be consistent growers than non-innovators. And at the opposite end, non-innovators were significantly more likely to have weak or struggling firms with very low absorptive capacity. Looking to the strategy implications of this, Table 6 cross-tabulates the growth-orientation strategy variable against the propensity for innovation with similarly significant effects.

---

Table 6 about here

---

The significant links between innovation and growth strategy are very clear as is the converse. Lack of innovation in a firm is clearly linked to its lack of a growth strategy, though then causal directions are perhaps not quite so clear. Lack of strategy suggests that the structures and culture to support innovation will also be absent though it is also likely in some cases that the lack of innovative capacity in the firm means that growth objectives are unrealistic. Also, while the innovative firms do have more growth related objectives, it is the single-activity innovators who appear to be more focused on those types of objective.

### **FUTURE IMPLICATIONS FOR SMES**

Despite the resistance of some very small microfirms, it is already clear that the vast majority of SMEs, whatever their driving motivations and business expectations, have become part of the wider ICT revolution to the business environment. This has increased their need to have up-to-date knowledge of ICT applications and of how to manage and use the massive

increase in connectivity that ICT supports both within firms and between them. The Internet also offers significant opportunities for improving competence, skills and understanding through rapid access to relevant and timely information.. More advanced ICT adoption seems to be linked to size, industry, and the growth-orientation of the owners. However, it is also clear that the implementation of ICT is also dependent on the type of owner manager and their attitude, the more proactive owners adopting ICTs to a higher extent, thus further developing their absorptive capacity. The process seems to be an iterative virtuous circle. However, the common SME impediments to innovation and knowledge creation have not gone away. This lack of competences and skills of many SMEs, especially the microfirms, adversely affect not only managers and staff, but also the firm's capacity to absorb new knowledge, communicate and sell its own knowledge effectively. The most important constraint on SME growth and networking lies in the career motivations and personal expectations of individual small firm owner and manager, and the reactive or static strategies that flow from this. If an owner wants to earn no more than a living as an individual or as a household then growth past a certain point, or even any real growth at all, is not on the agenda. Furthermore, if the mode of earning a living is also bound up with a certain lifestyle (informal, anti-bureaucratic, alternative, loose, individualistic, etc.), many decisions will be based on non-business criteria. This is not a milieu conducive to the establishment of good management or systematic innovation and can induce a vicious spiral. It is estimated in Britain that some 50 per cent of new firms fail within 4 years.

On the positive side, the findings above indicate a strong response to development initiatives from proactive SMEs with their strategic approach to growth (as opposed to tactical or reactive approaches). The implication is that strategic planning skills will also be in stronger demand among successful SMEs in the future. This conclusion is supported by OUBS studies in management development which have linked formal management development policies and a learning supportive environment with SMEs that have a growth strategy. However, these more strategic and structured firms (the ones most likely to develop a properly integrated strategy that embraces a planned use of ICT, e-learning and knowledge management practices) remain in the minority (Thomson et al, 2001; Gray, 2004). More research is needed into the defining characteristics of these firms and the personal development of their founders to determine whether educational histories and cultural effects influence expectations and strategy setting styles in ways that can be taught.

After a survey of 1,000 firms in the north-west US state of Washington, Liao and colleagues (2003) concluded that 'without certain prior knowledge, organizational responsiveness of growth-oriented SMEs will be curtailed'. The findings from the SERT surveys in Britain strongly support this conclusion. The challenge is how to provide that prior knowledge in more SMEs. For the small firms that do wish to be more proactive, the existence of a formal policy concerning management development and ICT strategy seems likely to be one requirement (Pettigrew, 1997; Thomson and Gray, 1999). Formal policies are more in evidence in organisations which give high priority to management and staff development and to the development of the firm as a learning organisation. The forces that seem to impel innovative SMEs towards this more formal approach reflect clear links between competitive pressures and the need to manage and generate knowledge effectively. The successful SMEs of the future are likely to be those that the development of absorptive capacity seriously. To help them, more research is needed on the nature and genesis of a firm's capacity to absorb and use knowledge effectively.

# **EXPERIMENTAL DIAGNOSE OF WOULD-BE ENTREPRENEURS IN DIFFERENT CULTURAL SETTINGS**

DIETMAR GRICHNIK\*

\* Dietmar Grichnik, Assistant Professor, Department of Business Administration and Financial Services, Heinrich Heine University Duesseldorf, Universitaetsstr. 1, D-40225 Duesseldorf (Germany); email: digri001@uni-duesseldorf.de

## **ABSTRACT**

This paper presents a model of entrepreneurial risk-taking behavior in two different cultural settings. Young entrepreneurs and entrepreneurship students in Germany and the United States were researched to evaluate the model and to identify cultural differences in the decision to start a company. The central research question was: How does the cultural context influence the decision-making and risk-taking behavior of entrepreneurs? The overall results of this comparative study indicate that significant differences between entrepreneurs and non-entrepreneurs in risk-taking behavior are culturally driven. These results confirm earlier U.S. studies that distinguish between risk propensity and risk perception with respect to entrepreneurs' risk behavior and extended these results to an international, intercultural sample. The results of this study identify cultural context as a key factor for the differences in entrepreneurial risk behavior. Also, these results allow potential entrepreneurs to use the conducted experiment as an individual diagnostic instrument; this makes it possible to identify individual anomalies in risk and decision-making behavior contributing to a better understanding of suitable entrepreneurial behavior as well as to reveal discrepancies between self-assessment and actual behavior. These results also present a set of instruments, techniques and a framework for an improved understanding of potentially attractive, but risky, start-up opportunities.

## **INTRODUCTION**

The crux of the following thoughts is that it cannot be unambiguously proven that entrepreneurs' propensity towards risk-taking is significantly higher than that of other financial decision-makers such as, for example, managers (Brockhaus 1980). Nevertheless, rational start-up considerations seem to confirm that entrepreneurs tend to accept higher risks in the step towards self-employment than those who decide to remain in dependent employment (Bird 1989). A reason is the young entrepreneurs' specific view of risks in comparison to other economic actors' risk perception (Palich/Bagby 1995). Supportive empirical evidence is, however, uncommon: Whereas there is research on the risk aspects of young venture financiers' investment decisions (Zacharakis/Shepherd 2001), there are to date only a few studies that analyze risk-taking behavior from entrepreneurs' point of view (Palich/Bagby 1995; Forlani/Mullins 2000). It is,

however, undeniable that the willingness for risk-taking is central to the decision to be entrepreneurially self-employed and to deal with the associated entrepreneurial risk (Busenitz/Barney 1997). The key elements of the founder's entrepreneurial risk-taking behavior, risk perception and risk propensity (Sitkin/Pablo 1992) influence whether a venture is realized and, if so, which kind and/or level of entrepreneurial risk will be accepted (Forlani/Mullins 2000).

If you assume with Simon, Houghton and Aquino (1999) that risk perception influences the decision to start-up a company and risk the step towards self-employment, the question arises: what influences individual risk perception and the associated risk-taking behavior? A few studies confirm that the decision-making process, in particular the decision-maker's receptiveness of cognitive biases, can reduce his perception of risk (Busenitz/Barney 1997; Palich/Bagby 1995). Cognitive biases are subjective or predisposed opinions that can originate from specific decision-making heuristics. As a result of their cognitively limited information processing capacity, individuals neither search comprehensively for relevant decision-making information, nor do they assess it completely accurately. To handle these restrictions, they apply decision-making heuristics in the form of rules of thumb and simplify the perceived decision-making situation, which can lead to cognitive biases (Simon/Houghton/Aquino 1999). Although the application of decision-making heuristics can lead to quite good results and can be particularly efficient (Tversky/Kahneman 1974), the heuristically impacted start-up decision is highly risky.

Particularly individuals facing the decision to establish a company and to change from an alternative application of their working time to self-employment are confronted with a decision-making problem which tends to exceed their cognitive information-processing capacity and which is inevitably produced by a high degree of uncertainty, modernity, emotions and time pressure (Baron 1998). In their U.S. study, Simon, Houghton and Aquino (1999) identify overconfidence, the illusion of control and the belief in the "law of small numbers" as the three central biases of the risk-taking decision within the start-up decision's framework. On the other hand, international comparisons of differing entrepreneurship cultures confirm, besides overconfidence, the influence of worry about risk-taking in German entrepreneurs' start-up considerations (Frederick et al. 2002). Except for the risk propensity (Schade/Steul/Schroeder 2002) that is central to risk perception (Weber/Milliman 1997), the cognitive biases of overconfidence (Cooper/Woo/Dunkelberg 1988) and worry (Schade/Kunreuther 2002) should be included as influencing factors in the start-up considerations.

In an international comparison it must be taken into account that the start-up decision's selected cognitive goal factors are, in turn, influenced by the social and cultural background of the entrepreneurs' country of origin (Hunt/Levie 2003, George/Zahra 2002; Hofstede 2001; Busenitz/Lau 1996). According to intercultural entrepreneurship research studies (Hayton/George/Zahra 2002), behavioristic phenomena like attitudes and perceptions are culture-specific so that cross-cultural comparisons are either aimed at inter-culturally valid phenomena, or require a context-dependent result interpretation at the risk of culture-specific constructs.

## **MODEL AND HYPOTHESES**

To research actual risk-taking behavior in respect of entrepreneurs' personal and context-applicable characteristics, the determinants of risk-taking behavior have to be understood.

Whereas the normative theory of decision making makes no differentiation here, and to some extent equates risk-taking behavior and risk propensity, the descriptive theory of decision making identifies risk-taking behavior's key influencing factors. Consequently, the decision-making behavior under risk results from the combination of risk propensity and perceived risk (Weber/Milliman 1997).

Here a risk propensity should be understood as the decision-maker's personal trait that influences the risk-taking behavior, but does not determine it. This attitude concept does not correspond to the psychological attitude concept: Fishbein/Ajzen (1975, 6) summarize the posture's character in three constituting characteristics: "... the notion that attitude is learned, that it predisposes action, and that such actions are consistently favorable or unfavorable toward the object". Risk propensity, as the employed term, does not here possess this reference to object. On the contrary, a risk propensity is here object-independent and thus a relative constant personality trait that is only transformed by exceptional events in the decision-maker's environment (Weber/Milliman 1997).

Conversely, the perceived risk is essentially determined by the situational factors – in the research context to some extent by the venture's characteristics. The objectively presented and/or natural risk is transformed by the (risk) perception process. The result is the perceived risk. Consequently, in respect of the start-up consideration, it can be deduced that the decision-maker's personality traits, the venture's characteristics and the context factors influence the start-up decision more than the risk perception's transformation processes. A decision-maker's worry can to some extent be regarded as a personality trait that is molded by financial context factors, such as the economic situation, and by cultural context factors, such as national mentalities and fundamental moods, and thus lead to differences in risk perception.

Based on the insights of research into success factors, one can distinguish between a micro- and a macro-level in respect of context factors. To some extent the individual's financial status at the time of the start-up decision influences the assessment of the venture's perceived risk on the micro-level. Conversely, from the economic macro-context, the state's financial promotion programs are influenced by start-up considerations. The social and cultural norms have a corresponding effect as macro-factors, whereas the entrepreneurs' direct social environment influences the micro-level. In addition, note that the influence factors are interdependent: cultural context factors (2003, Hunt/Levie 2003, George/Zahra 2002, Hayton/George/Zahra 2002, Hofstede 2001) shape personality traits such as risk propensity and risk perception and consequently decision-making behavior.

To summarize, the three following hypotheses can be derived for the empirical test:

*Hypothesis 1: The choice between the ventures is determined by the entrepreneur's different perceptions of these venture-related risks and by his individual risk propensity, overconfidence and worry (Schade/Kunreuther 2002, Forlani/Mullins 2000, Simon/Houghton/Aquino 1999, Palich/Bagby 1995).*

*Hypothesis 2: The differences in the entrepreneurs' risk-taking behavior are largely shaped by the cultural context (Hunt/Levie 2003, George/Zahra 2002, Hayton/George/Zahra 2002, Hofstede 2001).*

*Hypothesis 3: Risk perception functions as the central mediator for the cultural influence on the entrepreneurs' risk-taking behavior (Hunt/Levie 2003, George/Zahra 2002, Hayton/George/Zahra 2002, Hofstede 2001).*

For the empirical testing of these hypotheses, the following structural model in respect of risk-taking behavior during the start-up decision (see Figure 1), should be examined.

-----  
Figure 1 about here  
-----

In the centre of the model is the entrepreneur who makes his start-up decision through the choice of a venture and reveals a certain risk-taking behavior. How the entrepreneur assesses the chances and risks of a specific start-up intention depends, in turn, on his personal dispositions. Risk propensity (risk-avoider vs. risk-seeker) and perception of a specific risk (risk perception) play a decisive role. Personality characteristics, such as a tendency toward overconfidence (overconfident versus non-overconfident) and the expression of worry (worrier versus non-worrier) have a particular influence on the start-up decision. The decision manifests itself during the choice of one of the presented start-up alternatives which are distinguished from one another in respect of the risk profile. Risk is therefore defined as the positive and negative (standard) deviation of a target value and consequently also includes chance (Forlani/Mullins 2000). The particular risk associated with the venture is determined by the extent and probability (positive or negative) of deviation from the profit target (risk 1-4). The four ventures (white, purple, yellow, and pink) can be positioned in an unambiguous sequence (risk scoring) according to the specific degree of risk. As a control, the micro-context is revealed in the fundamental personality traits, the personal risk history and the individual risk perspectives. The macro-context flows into the analysis as a cultural context through the combination and comparison of the samples from the United States and Germany.

## FINDINGS

To empirically test the theoretically assumed dependencies between decision and risk-taking behavior's fundamental influencing factors during a start-up, two examples from various cultural contexts are required. For the model and hypotheses test a similar test design was developed and applied in Germany and the United States. The total sample is comprised of 254 (young) entrepreneurs and graduate entrepreneurship students in Germany (University of Cologne, University of Wuppertal, Business Plan Competition Cologne; n=124) and in the United States (Case Western Reserve University, Cleveland/Ohio; n=130); a group of 51 entrepreneurs (20%) versus a group of 201 non-entrepreneurs (80%). On average the participants were 29 years old within a range from 20 to 59 years old. The total sample consisted of 177 male and 74 female test participants.

Consistent with previous research on entrepreneurial risk-taking behavior (e.g., Forlani and Mullins 2000, Simon, Houghton and Aquino 1999, Palich and Bagby 1995), this study examines entrepreneurs and students' responses to a research design to measure behavior and personal dispositions. Entrepreneurs and entrepreneurship students were asked about their perception of risk and choice among a series of hypothetical new ventures with the choice being influenced by: the pattern of outcomes anticipated in each venture; the differing perceptions of those risks; and the differences in the personal propensities to take risks. A 2x2 full factorial within subjects experimental design was applied to manipulate the variability and hazard associated with the

outcomes of the new ventures. All four ventures had equal expected values, but different standard deviations of the predicted outcomes. In the non-experimental part of the research, the interviewees were classified into risk avoider and risk seeker measuring risk propensity indirectly by testing the choice of lotteries. Overconfident and non-overconfident individuals are differentiated by the perceived survival odds of the new venture in comparison to the survival rate of a competitive venture (Cooper, Woo and Dunkelberg 1988). Applying the established worry domains questionnaire (Tallis, Eysenck and Mathews 1992) worriers and non-worriers could be distinguished by an overall worry score based on five different worry domains. We controlled for individual differences such as age, gender, occupation and risk experience (entrepreneurial experience, family entrepreneurs, investment experience). The findings are:

*Hypothesis 1 appears to be confirmed and cannot be rejected:* in respect of the international sample of entrepreneurs it proves that the start-up decision, in the form of the tested risk-taking behavior, is sufficiently determined by the risk propensity, risk perception, worry, overconfidence and the cultural context ( $R=0.7$ ;  $R^2=0.49$ ) and that the tested decision-making model is significant ( $p<0.001$  through both the multi-linear as well as the logistic regression, see Table 1 and Table 2):

-----  
Table 1 about here  
-----

The overconfidence and risk perception parameters (risk 2, risk 4) in the overall model make a significant behavior prediction possible. Because a substantial precondition of the model was not fulfilled with the assumption of variance homogeneity (see Table 1 Point 5), the analysis of the logistical regression is expanded. This method has the advantage of being essentially free of assumptions. As the sole precondition, the predicting characteristic must be applied in a binary manner, which provides the solution that the dependent risk-taking behavior variable is dichotomized. The results of the logistical regression (Table 2) show that the model is significant and can essentially be attributed to overconfidence and risk perception.

-----  
Table 2 about here  
-----

*Hypothesis 2 appears to be confirmed and cannot be rejected:* the difference between entrepreneurs and non-entrepreneurs in respect of risk behavior varies significantly between the total sample's cultural contexts. The difference in the risk-taking behavior between entrepreneurs and non-entrepreneurs is significantly higher in the German context than in the U.S.-American context. Contrary to a widely accepted stereotype, the German entrepreneurs – in the control of the mentioned variables from the micro-context – choose for more risky ventures than their U.S.-American counterparts (see the variance analysis's results in Table 3):

As shown by Table 3, the interaction from being an entrepreneur and cultural context becomes significant ( $p=0.02$ ), German entrepreneurs exhibit less risk value, in other words, they take higher risks with a purchase than the U.S.-American entrepreneurs. With the non-entrepreneurs in both the cultural contexts, the opposite occurs.

-----  
Table 3 about here  
-----

*Hypothesis 3 appears to be confirmed and cannot be rejected:* the dominant properties of risk-taking behavior are risk perception and overconfidence. The more pronounced the overconfidence and risk perception, the higher the risks that are taken. The influence of the cultural context on entrepreneurs' risk-taking behavior is conveyed through the risk perception, as these variables' interaction analysis shows (see the results of the variance analysis in Table 4):

As shown in Table 4, the interaction from being an entrepreneur and cultural context and risk perception is significant at a 10% level of significance ( $p=0.09$ ). Furthermore, a principal effect is indicated in the risk perception (here exemplary for the venture purple). Persons with supramedian risk perception (here: risk perception of the venture purple) exhibit less risk value, in other words, they take higher risks when venturing. German entrepreneurs exhibit less risk value, in other words, they take higher risks. This effect is more strongly pronounced by U.S. entrepreneurs than by German entrepreneurs. The opposite is true of non-entrepreneurs in both cultural contexts.

-----  
Table 4 about here  
-----

The results of the model and hypotheses test imply that the model has been sufficiently well determined by the analyzed predictors and that none of the 3 hypotheses can be rejected.

## IMPLICATIONS

The results imply that the cultural context had a significant influence on the risk-taking behavior and that the risk perception functioned as a mediator. This insight helps to refine the understanding of entrepreneurial decision behavior in that, contrary to the normative theory of decision making, it postulates to inter-culturally distinguish between the risk propensity of and the risk perception for entrepreneurs' risk behavior. To sum up, one can state that:

1. The results confirm earlier U.S. studies to distinguish between risk propensity and risk perception in respect of entrepreneurs' risk behavior.
2. This is proved in respect of an international, intercultural sample.
3. The cultural context has been identified as a key factor for the differences in entrepreneurial risk behavior.
4. From the second and the third conclusion it can be deduced that the external validity of national start-up studies can be decreased in an international context.

Nevertheless, the limits of the employed methods are clear: the experimental base has advantages for the internal validity, but the experiment is not real and not linked to real cash flows, through which a question regarding the external validity arises: For which populations, context, treatment and measure variables can the measured effect be generalized? It can thus be established that the

experiment's laboratory situation was moderated to such a degree that the interviewees were presented with an individual risk profile as a feedback from their test result to provide the most authentic – realistic – answers. The majority of the interviewees made use of the feedback possibility.

A further possible problem could be that the measurement of the risk propensity is not accurate. An attempt was made to solve this problem by also asking the interviewees about the risk propensity of the self-assessment and only adding this information afterwards. On the other hand, the risk propensity was analyzed and evaluated indirectly by a lottery test.

Moreover, it can be noted that with the manipulation of the risk, the profit is also manipulated to keep the predicted cash-flows' expected values in the four ventures equal. In reality this is unlikely, and consequently reduces the results' external validity.

Furthermore, the study is limited to the start-up decision's key personal, and a few context-applicable, influence factors. Other factors such as team-decision processes and competencies remain unconsidered. Nevertheless, with the presented properties, the tested models reveal a sufficient degree of decisiveness in respect of psychological constructs.

The essential implications for entrepreneurship research can be summarized. The experimental project had the advantage that the internal validity was the purpose of theoretical test: risk-taking behavior has been shown to be a function of the risk perception and of other personal factors. Contrary to the assumptions of the normative theory of decision making, the risk-taking behavior, as a fundamental component of the start-up decision, is not exclusively based on the risk propensity and, as a result, supports the application of the descriptive theory of decision making in entrepreneurship research. However, with regard to the external validity of the hypothetical stimuli and of the group of test persons, it is possible to critically assess the experiment's initial analyses. A solution to this dilemma of the limited possibility to generalize the gained results could consist of using individual entrepreneurs' case as a behaviorist diagnostic initiative. Although this may contradict the strict economic principle in respect of the non-individual case examination, there is no contradiction here with regard to fundamental interdisciplinary, or behavioristically formed, entrepreneurship research.

This simultaneously facilitates the implications of entrepreneurship education. It is thus possible for "would-be entrepreneurs" to be used as an individual diagnostic instrument, making it possible to, on the one hand, identify individual anomalies in risk and decision-making behaviors and, consequently, contribute to a better understanding of suitable entrepreneurial behavior as well as to reveal discrepancies between self-assessment and actual behavior. On the other hand, this project offers a set of instruments, techniques and a framework for an improved understanding of potentially attractive, but risky, start-up opportunities. In ideal circumstances, a perfect fit between the personal start-up dispositions and the characteristic of the market opportunity as an entrepreneurial action field would be aspired to (Shane/Venkataraman 2000).

**DRIVERS OF EFFICIENCY IN SMALL SERVICE FIRMS:  
A DATA ENVELOPMENT APPROACH**

## **Abstract**

We explore the drivers of efficiency in very small service firms. Efficiency of the firms is established through a Data Envelopment Analysis (DEA). DEA uses input and output relationships to derive a relative efficiency measure for the individual firm. This relative efficiency measure reflects the potential increase in output of a firm, given a level of inputs. The average level of efficiency in this sample, given the input and output categories specified, is 50%. The empirical results are robust against different model specifications.

The study, based on 2125 data points, suggests that efficiency of firms is higher for larger firms, providing a broad set of services. In addition, the average efficiency of firms varies with region: firms in urban areas are more efficient than in rural areas. Soft franchising appears to have a positive impact on efficiency, whereas hard franchise has not. When firms grow older, they become less efficient.

Firms can only marginally increase their efficiency by adjusting their size towards an optimal size. This reinforces the argument that very small firms are not able to react on temporary changes in the market. These firms are just too small to adjust inputs downwards, in times of recession. Surprisingly, small firms may be not as flexible as they are usually assumed to be.

## I. INTRODUCTION

In this paper we explore structural factors that explain variance in efficiency of real estate brokerages. Brokerages firms in the Netherlands are typically very small and therefore can hardly adjust their resources downwards. In addition, because of their limited size, they also have little influence on their outputs. Their level of output is highly dependent on the residential homes market. Together this makes firms vulnerable to large fluctuations in performance from year to year. Therefore we expect a high variation in efficiency of the firms.

In the first section of the paper, we derive a performance measure of the firms. A performance measure such as shareholder value is not available for small firms; therefore we use an efficiency measure. Data Envelopment Analysis (DEA) provides a *relative* efficiency measure of individual firms, based on the input and output relationships of each firm. Being a non-parametric method, DEA can deal with multiple inputs and outputs categories without specifying a production function up front. In the second step, we regress this efficiency measure on a number of firm characteristics and market variables.

The paper is structured as follows. Section 2 describes efficiency of brokerage firms, factors that explain differences in efficiency, and residential brokerage firms in the Netherlands. Section 3 explains the background of efficiency analysis with the emphasis on Data Envelopment Analysis. An overview of the collected data, variable measurement and used methods is reported in section 4. Section 5 provides the empirical results of the study. We end with a summary and conclusion in section 6.

## II. LITERATURE REVIEW

### *Efficiency of brokerage*

The long lasting stream of literature provides contagious results about the efficiency of real estate brokerage firms. Earlier studies mainly stressed the inefficient nature of the industry. Different explanations for this inefficiency that are provided are the level of excess capacity (Yinger, 1981), monopolistic nature of the industry (Miller and Shedd, 1979; Crockett, 1982), the commission structure for services provided and the existence of entry barriers (Wachter, 1985). Opposing views about the efficiency of these firms are hold by Schroeter (1987) and Knoll (1988). From a DEA analysis on brokerage firms in the US, Anderson et al. (1998) find an average efficiency score of 50%. This score implies that the average firm can increase the level of output with 50%, given the same input level.

### *Drivers of efficiency in residential brokerage*

#### *Scale*

Zumpano et al. (1993) suggest that most residential brokerages are too small to take advantages of economies of scale. They derive this conclusion from the shape of average costs as a function of firm size. A larger scale makes it possible to specialize employees in particular service types and therefore leads to a higher efficiency.

#### *Franchise*

The impact of membership of a franchise chain might be two-fold. Franchise membership has advantages in raising capital at lower costs, in pooling advertising activities, and in making knowledge and expertise accessible to affiliates. However, members of franchises can also shirk effort, because the franchise reputation gives them enough transactions, and therefore they might

engage in free-rider behavior (Anderson et al. 1998). Empirical evidence from Anderson et al. (1998) suggests that franchise membership has a negative impact on efficiency. However, in their setting they explore the impact of being a member of any franchise, without providing information about the terms and conditions of different franchise formulas.

### *Limited liability (BV)*

Limited liability may insure firms against personal negative implications of being inefficient. Therefore, having limited liability, for example, by using the fiscal entity private limited company, is expected to have a negative impact on efficiency. However, Anderson et al. (1998) failed to find empirical evidence for the impact of this limited liability on efficiency.

### *Economies of Scope*

The service proposition of real estate brokers in The Netherlands consists of four main services: (1) advising households selling property, (2) advising households buying property, (3) the valuation of houses and (4) selling new built houses on behalf of developers. On top of that they provide services as mortgage and insurance brokers, rental services, consulting services etc. Dutch real estate brokers are not allowed to advise both the selling and the buying party, the traditional position of the middleman.

Zumpano and Elder (1994) report significant economies of scope in the real estate brokerage industry. Brokers that offer different services can for example share the (fixed) costs of the back office function. However, different services need different expertise and therefore, employees within a brokerage firm probably need to specialize. Therefore, to be economically feasible, the different service categories should be large enough to make the investments worthwhile. Recent trends in brokerage services suggest that firms focus on a narrow range of services, for example

only advising buying households, or only act as a valuator. This trend is partly explained as a result of niche marketing, and partly (especially in the case of valuation) as an efficiency-driven strategy.

### *Firm age*

The impact of firm age on efficiency is two-fold. Longer operating firms have a more extensive network (and reputation) and therefore might attract more customers. In contrast, the extensive network might lead to overconfidence because firms believe customers will be attracted based on their reputation only (Anderson et al., 1998). Next to reputation effects, Jovanovic (2001) positions that older firms have more problems to adjust themselves to a changing environment. In the context of brokerage firms, the major change is the introduction of the internet as a substitute for traditional multiple listing services.

### *Market density*

When markets are more dense, i.e., in urban areas, there will be more properties for sale and therefore a higher level of transactions. This increases the proximity of the brokerages to the properties for sale and therefore reduces travel time. In addition, in dense markets, there will be more competition between brokerage firms. Together, a greater market density is expected to lead to a higher efficiency.

## **Residential brokerage in the Netherlands**

Almost 80% of existing housing transactions (180.000 per annum) in the Netherlands are undertaken through three Multi Listing Services (MLS). The largest of the three, run by the leading trade association, has a 65% market share in residential sales. Only members of the trade association (about 2000 agency firms) have direct access to this MLS.

Selling houses is the most important service provided by agents, followed by buying agency services and valuations. Recently, buyers less commonly use buying agents to look for properties and to negotiate purchases. There is no sharing of fees between selling and buying agents. Only a minority of real estate offices sells new houses. They tend to do such work for low fees, relying on mortgage commissions and the hope of organizing the sale of the existing home of new house purchasers, when they are previous owner occupiers.

Compared to the US situation, real estate brokerage in the Netherlands is an extremely small-scaled business. The average agency sells about 100 houses a year and helps around 20 buyers. The median number of houses sold yearly is about 60. Studies have shown that there are few scale or scope economies in agency work and that the most profitable firms in relation to turnover are relatively small ones, employing about 10 people, with an annual turnover of 150 house sales and 25-30 house buyers. The profitability of larger firms is less volatile than that of smaller ones, making risk-weighted returns fairly similar (Ball, 2004). Few agencies fail.

Between 1987 and 2000, there were only an handful of bankruptcies. Firms, instead, tend to disappear as their proprietors tire of the business or retire from it.

There is some evidence of consolidation amongst estate agents themselves. The impetus towards consolidation is related to broader economies of scale associated with branding, etc. Scale and scope results are influenced by the fact that firms operate in larger networks (e.g., franchise chains or multiple outlet firms) that provide considerable scale benefits.

### III. EFFICIENCY ANALYSIS AND DEA

Early, mainly regression based techniques, used for assessing (in)efficiency of decision making units, have the common limitation in that they can handle only one dependent variable, i.e., only one output category. In addition, these techniques do not provide specific information about the causes of inefficiency (Bardhan, et al., 1998). To be able to include multiple input and outputs in regression based techniques an often subjective, a priori weighting scheme of the inputs and outputs, is needed.

Data envelopment analysis (DEA) is a non-parametric technique that establishes the relative efficiency of firms or individual decision making units (DMU's). The fact that DEA is a non-parametric type of efficiency analysis implies that no functional form a priori is needed to specify input–output relationships, although it is possible to suppress or enlarge the impact of an individual input or output in the efficiency scores (see for an example, Thanassoulis et al., 1995). DEA is also able to explore inefficiencies in all input or output category used for each observation (Bardhan et al., 1998).

The relative technical efficiency of a firm is calculated by forming the ratio of a weighted sum of outputs and inputs to be selected in a manner that calculates the Pareto efficiency measure of each firm subject to the constraints that an efficiency of 100% is the maximum achievable (Charnes et al, 1994, p. 6). The efficiency measure is the radial distance from the optimal production frontier. This frontier is based on the levels of each output category that is produced by the most efficient firms.

DEA scores produce *relative efficiency measures* and therefore the average efficiency in the population should be interpreted with some caution. The average efficiency, for example,

depends on the sample size in combination with the number of input and output categories. To control the impact of a large set of inputs and outputs on the efficiency measure Cooper et al. (2000) suggest to start with a small set of input and output and gradually enlarge this set to study its impact on efficiency.

Firms operating in a niche, producing only a limited number of output categories, can receive the same efficiency measure in comparison to firms that produces the whole range of output categories. Therefore, the benchmark for each firm, used to compute its relative efficiency, is the set of firms in the sample that have exactly the same input and output mix, be it in different proportions. The observation that the average efficiency from a DEA analysis is dependent on the sample size implies that levels of average inefficiency can not be compared between different samples. Thus, for example comparing the average efficiencies of firms in one industry in different countries provides biased results due to the unequal sample size of the studies (Zhang and Bartels, 1998).

There are two models most frequently associated with the DEA methodology: the CCR (“Charnes-Cooper-Rhodes”)-model measures efficiency under constant returns of scale (Charnes, Cooper, & Rhodes, 1978) and produces an “overall efficiency” rating. In contrast, the BCC (“Banker-Charnes-Cooper”)-model measures efficiency on the assumption of variable returns to scale leading to a “pure technical efficiency” rating (Banker, Charnes, & Cooper, 1984). When variable returns to scale are assumed, the relative benchmark of a firm are the firms that operate with a similar scale. With constant returns to scale, the relative benchmark of a firm are all other firms in the sample.

Since 1978, DEA is applied in an almost unlimited number of different settings, represented by the list of a bibliography of 472 published papers and dissertations between 1978 and 1992 by Seinfeld in Cooper et al. (1994). Examples of applications are efficiency analysis of non-profit firms that receive financial support from governments (e.g., Hollingsworth, 2003), the impact of non-controllable inputs and external conditions on efficiency of schools (e.g., Ray 1991), the impact of technological change on trends in efficiency of the textile industry in China (Wei, et al. 1995), and efficiency gains of making use of economies of scale in software maintenance (Banker and Slaughter, 1997).

#### **IV. DATA, VARIABLES AND METHODS**

##### ***Data***

Data was collected from an ongoing annual benchmark study among brokerage firms commissioned by the main Dutch trade organization of estate brokers. The annual survey covers input (personnel, costs) and output (volume and revenues), as well as demographic information as firm age, region, franchise affiliation, etc. To enhanced data comparability, we limit the analysis to firms that receive at least 75% of their revenues from residential transactions. A benefit of this restriction, is that it leads to less input and output categories for the Data Envelopment Analysis.

Three years of data were pooled in the database from 2000, 2001 and 2002. The total sample size is 2125 data points, 959 from 2000, 563 from 2001, and 603 from 2002. For 296 firms we have a complete panel, with data on all three of the consecutive years.

##### ***Data envelop analysis***

The dependent variable efficiency is computed through Data Envelopment Analysis (DEA). DEA estimates efficiency of units by assessing input-output relationships. Firms that produce more outputs are considered to be more efficient than firms that produce less output given the same values of inputs.

Labor is the dominant asset in services, and the division of labor within the firm is the main instrument brokers can use as an instrument to enhance efficiency. To compute the input-output relationships in this setting, we use four labor-related input measures. These are the number of brokers, assistant brokers, mortgage brokers and support staff, all measured in full time equivalencies. Output categories are the number of transactions in sold existing homes, bought homes, sold new homes, rented houses, mortgages, and number of valuations. Descriptives of the inputs and outputs are reported in Table 1.

-----  
Insert Table 1 about here  
-----

The descriptives indicate that the average brokerage is very small, with less than two brokers, 1.18 assistant brokers, 0.2 mortgage brokers and two supporting staff. To compute efficiency we focus on the constant return to scale DEA model (CCR). The variable return to scale DEA model (BCC) yields similar results.

### ***Variable measurement***

Firm age is measured in years since foundation of the firm (*Age*). The variable *Limited* measures whether the brokerage has limited liability. This is an indicator variable that is activated if the brokerage is a private limited company and is zero otherwise. The impact of franchise membership is measured by two dummy variables (*Franchise1*, *Franchise2*). Indicator variable

*Franchise1* is activated if the brokerage is a member of franchise 1 and 0 otherwise. *Franchise2* is activated when the firm is a member of franchise 2 and 0 otherwise. These two franchises are the largest in the Netherlands. The franchises have a different regime. *Franchise1* is an US based franchise that recommends strict enforcement of using the franchise name, and procedures. In contrast, *Franchise2* is a Dutch based franchise that leaves more individual freedom to the firm. In other words, it leaves more room for entrepreneurial behavior.

Three indicator variables are used to assess the impact of operating in four different regions within the Netherlands. (*Area1*, *Area2*, and *Area3*). The regions are the result of a cluster procedure based on the size of the market (number of sold house per annum), average prices of houses and scarcity of houses. *Area1* are the 4 largest cities of the Netherlands, markets with a large number of transactions, an average price level of properties and a scarce market. *Area2* is characterized by an average volume, high prices of the properties and a scarce market. *Area3* is a small market, with average prices of properties, and no scarcity. The fourth area, the reference group, are mainly rural areas. This is an area with low transaction volumes, low prices, and no scarcity.

Two competition measures are used. The first competition variable (*Share*) measures the pressure from firms outside the trade association. The second variable (*Entropy*) measures the concentration within the population of members of this association, as a proxy for competitive pressure. The correlation coefficient of the two competition variables is 0.04 (not significant), making it clear that two different dimensions of competition are measured.

The firm's economies of scope are measured by the number of different services a firm provides (*Scope*). These services are the output categories used for the DEA analysis. The range of this

variable is from one to six. Finally, firm size is measured by the number of full time equivalent employees (*Size*).

Using observations from more than one year in a DEA analysis might lead to a biased efficiency parameter, if for example new technologies lead to a higher efficiency in later years. A second factor that could impact the efficiency of brokerage in each year is changes in the residential properties market. To control for changing conditions in time we use indicator variables for two years, *Year2001* and *Year2002*.

### ***Methods***

The dependent variable efficiency is a bounded score, between 0 and 100 and often skewed with a bimodal distribution (Knox Lovell, et al., 1994). Therefore, ordinary least squares provide inaccurate estimates of coefficients. To overcome these problems we estimate a Tobit regression. To explain the variance in relative efficiency measure by the variance in the set of independent variables we estimate the following equation:

$$\begin{aligned} Eff_{it} = & \alpha + \beta_1 * Entropy_{it} + \beta_2 * Share_{it} + \beta_3 * Age_{it} + \beta_4 * Limited_{it} + \beta_5 * Franchise1_{it} \\ & + \beta_6 * Franchise2_{it} + \beta_7 * Area1_{it} + \beta_8 * Area2_{it} + \beta_9 * Area3_{it} + \beta_{10} * Size_{it} + \beta_{11} * Scope_{it} \\ & + \beta_{12} * year2000_{it} + \beta_{13} * year2001_{it} \end{aligned}$$

In which *i* is the firm and *t* is a period index. Using a panel dataset implies that the benchmark of an observation in the DEA is the same observation in another year or a different observation.

This assumes that the technology is constant in time. This is a reasonable assumption in this setting, even though the breakthrough of internet took place somewhere in the research period.

Next to using the panel dataset we also execute a cross-sectional analysis for firms that have three years of observations.

## **IV. EMPIRICAL RESULTS**

The results section incorporates four stages of analysis. First, we compute the efficiency of firms. Second, we explain variation in efficiency through a set of independent variables, which are related to market characteristics and firm characteristics. Third, we explore how much firms can increase their profits when they are able to increase their efficiency level. Finally, we check whether results are robust when we average the input and output categories over the three years in the sample. The motivation for this analysis is that firms have little influence on the level of output in one year.

### *Efficiency*

The DEA analysis is based on four input categories and six output categories. The descriptives for three different DEA efficiency measures are reported in table 2.

-----  
Insert Table 2 about here  
-----

Average efficiency with constant return to scale ( $Eff_{CCR}$ ) based on the pooled three year data is 50.78. This implies that on average brokerages firm can realize 49% more transactions with the inputs used. Only a small part of this inefficiency is due to scale inefficiency, i.e. firms have the “wrong” scale. Since the efficiency scores from the BCC-model are by definition equal or larger than the efficiency score of the CCR-model, scale efficiency can be computed by  $\Theta = \sum(Eff_{CCR} / Eff_{BCC})$  (Cooper et al., 2000). In this industry, scale efficiency is 95,68. Therefore adjusting the scale of operations will not lead to major efficiency improvements. This result contrasts the finding of Anderson et al. (1998) who find that the largest part of inefficiency is due to having a sub-optimal scale. 48% of the firms in the sample have increasing returns to scale and therefore should increase size, whereas 43% have decreasing returns to scale, and therefore are too large.

To assess the stability of the efficiency measure, we also computed efficiency of brokerage in each year ( $eff_{year}$ ). Correlation between  $eff_{year}$  and  $eff_{CCR}$  is 0.934 ( $p < 0.01$ ). This means that it makes no (large) difference whether the benchmark is derived from firms in the same year or in the complete time-series. However, an artifact of DEA analysis is that a higher number of observations lead to a lower average efficiency. The reason for this mechanism is that with many observations each individual observation has more reference units increasing the probability that other reference units will be more efficient (Zhang and Bartels, 1998; Staat, 2001).

The DEA technique provides insights in the output categories where the highest efficiency gains are possible. Of the six output categories three have an inefficiency level of more than 10%. These are the number of mortgages (18%), the number of sold new houses (51%), and the number of valuations (13%). In the case of mortgages and new houses, the explanation lies in the structure of compensation: the financial reward for both services is high. In the case of valuations, the inefficiency is not compensated.

The efficiency measure from the DEA technique is dependent on the input and output relationships specified. Therefore, to explore the stability of the efficiency numbers we specify different input and output combinations. For example, 86% of the sample has no financial advisors; this input category might therefore have a large impact on the efficiency score. In addition, revenues for valuing homes are much lower than for brokerage services. This suggests that being efficient on this output category is less important for firms. Correlation coefficients between efficiency measures of these different input-output specifications are reported in Table 3.

-----  
Insert Table 3 about here

-----

Based on the correlation coefficients of the alternative efficiency measures the efficiency number is robust against different input-output specifications. The lowest correlation coefficient is 0.8. In sum, we find that based on the specified input and output relationships there is considerable room for efficiency improvements in the firms. The relative differences in efficiency between firms however seem to be robust against different input-output specifications as indicated by the high correlation coefficients of the different efficiency results. Most of the inefficiencies are found complementary services provided such as valuation of homes and the number of mortgages. Only 5% of inefficiency can be gained by adjusting the firms to the optimal scale.

### ***Drivers of efficiency***

In this section, we explain the differences in efficiency from firm related factors, such as its size, membership of a franchise, and age, and market related factors such as degree of competition, and the impact of regions. A description of all variables used in the analysis is reported in Table 4. Correlations between all metric variables are reported in table 5.

-----  
Insert Table 4 & 5 about here  
-----

The impact of the independent variables on the efficiency measures are reported in Table 6.

-----  
Insert Table 6 about here  
-----

The  $R^2$ -adjusted of the analysis is 0.103. The two competition variables (*Entropy* and *Share*) are not significant. Firms that have a private limited company as legal identity (*Limited<sub>it</sub>*) are on average 3.447 points more efficient than firms without a private limited company ( $z=3.140$ ,

$p < 0.01$ ). This difference is significant (t-value is 5.302,  $p < 0.01$ ). A possible explanation is that Private limited firms are on average 2.3 FTE larger.

The area-dummies have an impact on the efficiency score. Firms with affiliations in *area1* are on average 8.403 ( $z = 5.188$ ,  $p < 0.01$ ) more efficient than firms from area 4 (the reference group).

Firms with affiliations in *area2* and *area3* are on average respectively  $-6.123$  ( $z = -3.190$ ,  $p < 0.01$ ) and  $-2,514$  ( $z = -1.787$ ,  $p < 0.08$ ) less efficient than area 4. Operating in a metropolitan area (*area1*), with a dense market, in a highly competitive environment, appears to have a beneficiary influence on firms' efficiency.

Firms that are a member of *Franchise2* are on average 7.258 more efficient ( $z = 2.669$ ,  $p < 0.01$ ) than firms that are not a member of a franchise chain. Being a member of *Franchise1* has no significant impact on efficiency ( $b = -2.543$ ,  $z = -1.347$ , ns). This suggests that the impact of franchise membership on the efficiency of brokerage is dependent on the type of franchise. Soft franchising, with room for entrepreneurship in the individual firm, enhances efficiency, hard franchising does not.

The number of services the firm provides (*Mix*) is also significantly associated with efficiency. Firms with a broad portfolio of services are more efficient than firms focusing on a narrow range ( $\beta = 1.847$ ,  $z = 3.719$ ,  $p < 0.01$ ). A (not tabulated) analysis of variance analysis (ANOVA) with efficiency as the test variables and *Mix* as the treatment variable indicates that this effect is linear. The average efficiency in the six product groups increases monotonically. Age has a marginal significant negative impact on efficiency. Older firms become less efficient ( $b = -0.501$ ,  $t = -1.824$ ,  $p < 0.07$ ).

The average efficiency of the brokerages differs significantly in the 3 years of the sample. Observations from the year 2000 are on average 7.771% more efficient than observations from 2002, being the reference group ( $t=6.315$ ,  $p<0.01$ ). A possible explanation is that after 2000, the residential property market became worse and therefore it was more difficult for brokers to close transactions efficiently.

Based on a comparison of the standardized regression coefficients, regional effects and the impact of observations from the year 2000 have the largest impact on efficiency. These factors can be considered as exogenous variables to the firms. From the more endogenous variables, size of the brokerage, the number of services supplied, and being a limited liable company has the largest impact on efficiency.

Finally, we use the efficiency score with variable return to scale as dependent variable ( $Eff_{bcc}$ ) (column 3 in table 6). The coefficients and significant levels are similar to the coefficients and significant levels of the model with  $Eff_{crr}$ . However, the  $R^2$ -adjusted increases from 0.103 to 0.150, indicating that the correction for non-linear volume effects, in the DEA measure, improves the model's explanatory power.

### ***Efficiency and profit***

DEA efficiency measure only reports whether firms use the available resources efficiently. To shed some light on the impact of efficiency on profitability, we regressed brokers' profits on the DEA efficiency measure. Profit is measured as the revenues of the brokerage minus operational costs. The results are reported in table 7.

-----  
Insert Table 7 about here  
-----

The regression results indicate that variance in efficiency can explain 14% of variance in profit and 17% in variance of profit per full time equivalent. A higher efficiency level of 1% is associated with a higher profit level of €2547 and €478 per FTE in a year.

### *Averaging efficiency over three years*

The descriptives of the input categories in table 1 indicate that the average brokerage is very small, with less than five full time equivalents. Such a small size implies a lack of flexibility in input resources. This implies that the labor force can only be adjusted upwards. Downsizing, as a reaction to a bad year, is hardly possible. Therefore, we also explored the efficiency on a longer time horizon. We averaged the input and output and drivers over the three years. For drivers that are indicator variables we averaged the variables and then adjusted them to 0 or 1. For example, if the firm was a limited liability company in two of the three years we gave it a 1 and zero otherwise. Results of this analysis are reported in Table 8.

-----  
Insert Table 8 about here  
-----

$R^2$  ( $R^2$ -adj) of the model is 14% (11%) which is somewhat higher than the model that uses time-series. This might be explained by the fact that the efficiency measure is more stable when it is computed over three years and therefore incorporates less noise. The set of coefficients has a similar sign compared to the signs of the time series model. However, due to the strongly decreased sample size and therefore the power of the test only some variables are significant. The significant variables that are associated with efficiency are *Franchise2* ( $\beta=28.191$ ,  $t=2.478$ ,  $p<0.05$ ), *Size* ( $\beta=0.978$ ,  $t=2.443$ ,  $p<0.02$ ) and *Mix* ( $\beta=4.870$ ,  $t=3.234$ ,  $p<0.01$ ). These three variables also had high standardized coefficients in the analysis from the time-series.

## VII. SUMMARY AND CONCLUSION

In this paper we explore drivers of efficiency in small service firms. Efficiency of the firms is established through a DEA analysis. DEA uses input and output relationships to derive a relative efficiency measure. This relative efficiency measure reflects the potential increase in output categories of a firm with a given level of input in comparison to efficient firms. Average inefficiency in this sample, given the input and output categories specified is 50%. Firms can only marginally increase their efficiency by adjusting their size to the optimal size.

The results from the empirical study suggest that efficiency of firms is higher for larger firms, firms that provide a broad set of services and firms that have a limited liability. In addition, the average efficiency of firms varies with region: firms in urban areas are more efficient than firms in rural areas. In contrast to Anderson et al. (1998), we find that franchise membership has an impact on efficiency. Soft franchising appears to have a positive impact on efficiency, whereas hard franchise has no significant impact. Finally, when firms grow older, they become less efficient. The empirical results are robust against different specifications. For, example we estimate efficiency per firm with in a yearly interval and an average over three years. The effect sizes of the independent variables were similar for both analyses.

Factors that have a favorable impact on the efficiency of brokerage firms are mainly exogenous variables, such as year and area. This reinforces the argument that very small business firms are not able to react on temporary changes in the market. The firms are unable to adjust the inputs downwards when the brokerages industry is in the downward trend of the conjuncture.

Surprisingly, small firms may be not as flexible as we think they are.

As usual, the results of the study should be interpreted in light of its flaws. First, the independent variables are assumed to have a linear impact on efficiency. However, some of the independent variables, for example firm size and age, could have a non-linear impact on efficiency. Second, the two competition variables have no significant impact on efficiency. This contradicts economic common sense, expecting a positive impact of competition intensity on efficiency.

This study suggests a number of potential avenues for future research. First, the regression equation explains only 11% of variation in the dependent efficiency variable. This suggests there is ample room for other factors that explain why some brokerages are more efficient than others. Second, we find that scale inefficiencies are low in this industry. The part of the sample that was too small and too large to profit from scale economies was both approximately 50%. This suggests that there is an optimal scale (or a set of optimal scales). Further research could shed more light on this. In addition, mechanisms that lead to optimal scales, such as need for coordination, opportunities for specialization could be explored. Finally, the sample for our study ended in 2002. Until that period, the industry saw very little innovations. However, in the period 2001-2003 we have seen the breakthrough of internet as an alternative for MLS. This innovation has a large impact on the operations of brokers' firms. The impact on the performance of firms is yet to be seen.

## TABLES

Table 1: descriptives of input and output categories used in the Data Envelop Analysis.

|                       | mean   | Median | stdev  | min  | Max     |
|-----------------------|--------|--------|--------|------|---------|
| Input <sup>1</sup>    |        |        |        |      |         |

| Size                | 0.570                         | 5.396** | 1.299                         | 10.958** |
| Scope               | 1.847                         | 3.719** | 1.911                         | 3.778**  |
| Year2000            | 7.771                         | 6.315** | 8.057                         | 6.446**  |
| Year2001            | 1.847                         | 1.351   | 2.231                         | 1.605    |
| R <sup>2</sup> -adj | 0.103                         |         | 0.150                         |          |

coefficients and z-values come from a Tobit regression.

The following regression model is estimated:

$$\begin{aligned}
 Eff_{it} = & \alpha + \beta_1 * Entropie_{it} + \beta_2 * Share_{it} + \beta_3 * Age_{it} + \beta_4 * Limited_{it} + \beta_5 * Franchise1_{it} \\
 & + \beta_6 * Franchise2_{it} + \beta_7 * Area1_{it} + \beta_8 * Area2_{it} + \beta_9 * Area3_{it} + \beta_{10} * Size_{it} + \beta_{11} * Scope_{it} \\
 & + \beta_{12} * year2000_{it} + \beta_{13} * year2001_{it}
 \end{aligned}$$

Table 7: impact of efficiency on profit.

|                             | Coefficient <sup>4,5</sup> | t-values | Coefficient             | t-values |
|-----------------------------|----------------------------|----------|-------------------------|----------|
| Dependent                   | Profit <sup>1</sup>        |          | Profit/FTE <sup>2</sup> |          |
| Constant                    | -33,990                    | -4.51**  | -4,000                  | -3.11**  |
| DEA efficiency <sup>3</sup> | 2,547                      | 18.85**  | 478                     | 20.72**  |
| R <sup>2</sup>              | 0.143                      |          | 0.168                   |          |

Notes:

\*\* means significance on the 0.01 level.

<sup>1</sup> Profit is defined as total revenues minus operational costs.

<sup>2</sup> FTE: full times equivalence.

<sup>3</sup> DEA efficiency is based on the CRR model (Constant returns to scale).

<sup>4</sup> coefficients and t-values are from a ordinary least square regression.

<sup>5</sup> Coefficients come from the following equation:

$$Pr\ ofit_{it} = \alpha + \beta * Eff_{it}$$

Table 8: drivers of efficiency (input and output categories are averaged over the years).

| Variable<br>(N=296) <sup>1</sup> | Coefficient <sup>2</sup> | z-value |
|----------------------------------|--------------------------|---------|
| Dependent                        | Eff <sub>CCR</sub>       |         |
| Constant                         | 66.605                   | 2.168   |
| Entropy                          | -7.399                   | -0.237  |
| Share                            | -16.242                  | -1.070  |
| Age                              | -0.017                   | -0.176  |
| Limited                          | 1.460                    | 0.425   |
| Franchise 1                      | -0.492                   | -0.073  |
| Franchise 2                      | 28.19                    | 2.478   |
| Area1                            | 5.974                    | 1.068   |
| Area2                            | -9.158                   | -1.418  |
| Area3                            | -5.261                   | -1.127  |
| Size                             | 0.979                    | 2.443   |
| Scope                            | 6.092                    | 3.181   |
| R <sup>2</sup> -adj              | 0.108                    |         |

<sup>1</sup>The dependent variable is the efficiency measure of the CCR model (Constant returns to scale). Input and output categories are first averaged over the three years before they are used in the DEA analysis.

<sup>2</sup> regression coefficients and z-values come from a Tobit regression.

$$Eff = \alpha + \beta_1 * Entropie + \beta_2 * Aandeel + \beta_3 * Age + \beta_4 * Limited + \beta_5 * Franchise 1 + \beta_6 * Franchise 2 + \beta_7 * Area1 + \beta_8 * Area 2 + \beta_9 * Area 3 + \beta_{10} * FTE + \beta_{11} * Mix$$

## **ABSTRACT**

Economic development is a complex process influenced by many economic and non-economic factors. Historically, rapid economic growth of a country was achieved through industrialization, and, entrepreneurship was considered to be one of the most important contributing factors.

The emergence of entrepreneurs in a society depends on the economic, social, religious, cultural and psychological factors prevailing in the society. They are also dependent upon awareness, motivational forces, and self-confidence in people. These skills, however, are latent in many women. Nearly 50% of the total population of a country comprises of women, and unless these skills are developed, and women are made equal partners in the development process, no development, in its truest sense, takes place in the country.

It is only when the upliftment of women takes place, the women move forward followed by the family, the village, and the nation. Today, given an opportunity, women want to do better things in lives. Government and non-government organizations must recognize this need, and women must be directed towards programs that encourage entrepreneurship.

In India, the national perspective plan for women in 1998-2000 aimed at the economic development and integration of women into the main stream of economy, with equality and social justice for all women. Many governmental agencies provide entrepreneurship development training programs for women, and 'Jansikshan Sanstan' (JSS) is one such government organization.

This paper seeks to study if the entrepreneurship development training programs, as provided by the JSS, leads to the emancipation of the women enrolled.

## INTRODUCTION

Economic development is not a mechanical process nor is it a matter of simply adding an assortment of factors. It is a complex process influenced by many economic and non-economic factors. It is, ultimately, a human enterprise, and like all human enterprises, its outcome is dependent on the skills, quality and the attitudes of the people who participate in such an undertaking.

Historical data validates that rapid economic growth of a country is achieved through industrialization, and entrepreneurship has been considered as a factor of paramount importance in influencing the pace of industrialization. This is evident as seen in countries like Japan, South Korea, Hong Kong, Singapore, Thailand, Malaysia, amongst others. Here, entrepreneurial development played a crucial role in the economic development of that country.

Unemployment is a malaise that can be stated to be at the base of all maladies affecting the economic development of a region, and the emergence of entrepreneurs in a society depends to a great extent on the economic, social, religious, cultural and psychological factors prevailing in the society. Women consist of nearly 50% of the total population of the country, and unless they are made equal partners in the developing process, and contribute to the economic growth of the country, no development takes place in its true sense. Entrepreneurial talents exist in all human beings, and its emergence is dependent upon creating awareness, providing motivational factors and building self-confidence. These latent skills must be developed in women to make them entrepreneurs. Self-employment is probably one of the most effective tools to tackle the growing problems of unemployment, and all across India, be it in rural, semi-urban or urban areas, there is a vast scope for self-employment, thereby building the Indian economy. The National Perspective Plan for Women in India, 1998 – 2000, was aimed at economic development and integration of women into the main stream of economy with equality and social justice for all women.

The objective of this case study is to determine if the capacity building, as taught by Janshikshan Sansthan (JSS), lead to the emancipation of women by building their entrepreneurial skills. In order to analyze the above objective, this study was divided into six sections.

1. Demographic profiling of Women Entrepreneurs (WE) i.e. age, education, marital status, family background etc.,
2. Capacity building effectiveness of skill-sets by JSS to WE,
3. Economic realization of skills into income generating activity by WE,
4. Whether emancipation of the women has taken place (individual level),
5. Effect on the Quality of life of WE (society level) and

6. Directional pointers for future course of action that needs to be undertaken to affect a profound change.

### **HYPOTHESIS OF THE STUDY**

This paper is based on the hypothesis that the emancipation of women takes place through entrepreneurship development programs. Acquiring a skill-set will lead to self-employment, attainment of financial independence, and the ability to make decisions. Indirectly, entrepreneurship development leads to the emancipation of a woman.

### **METHODOLOGY**

Both primary data and secondary data have been used in this study. The survey was conducted on the WE of 2 districts (Hyderabad and Ranga Reddy Districts) in Andhra Pradesh, India, who have received training and support in establishing their units. One hundred WE (50 from each district), were selected for this study. The data was collected by administering a structured questionnaire, keeping in view, the objectives of this study. The data was tabulated and analyzed. Secondary data was collected through newspapers, magazines, books, and through personal interviews with the officials of JSS.

### **SCOPE OF THE STUDY**

The scope of the study has been confined to WE enrolled in JSS program in the Hyderabad and Ranga Reddy districts of Andhra Pradesh.

In India, there exist several government agencies concerned with creating training programs and providing special schemes or offers to promote self-employment amongst women. The JSS is one such organization. They conduct awareness campaigns, provide the necessary training and equipment, and by making available credit facilities, encourage women to be entrepreneurs.

Tables I to V: Analyze the age, education, marital, and family background of the WE  
Tables VI to VIII: Data is collected and analyzed on their skill sets, and their ability to convert their skills into income generation activity.  
Likert five point scale is used to measure their emancipation at individual and at societal levels.

## TABLES

| Age group | Number of Respondents |
|-----------|-----------------------|
| 16-22     | 30                    |
| 22-28     | 26                    |
| 28-34     | 21                    |
| 34-40     | 17                    |
| Above 40  | 6                     |
| Total     | 100                   |

**Table No. I: Age of the Respondents and demographic profile of women entrepreneurs.**

Table No.1 shows the age of self employed women who have started their own units after JSS training in different activities.

Women at different age groups i.e. from 16 to 60 involved themselves in self-employment activity, to gain control over their lives.

Women who are in-between 16 to 22 of age, constitute more self employed number than any other age group. This could be because self employment is seen as an alternative for job employment, which is a welcoming sign.

In the recent years women at the age of 40 and above are also taking training programs in different activities and setting up their units which might mean that they have grown up children and they may want to convert their leisure time into constructive self employment activity.

We can interpret that women at all ages are willing to achieve economic independence provided they are given an opportunity.

| Particulars                  | Number |
|------------------------------|--------|
| Up to 5 <sup>th</sup> grade  | 65     |
| Up to 10 <sup>th</sup> grade | 23     |
| Up to High school            | 20     |
| Up to Bachelors              | 2      |
| Total                        | 100    |

**Table No.II: Literacy levels of women entrepreneurs**

Observing the literacy levels of women entrepreneurs in Table No.II, it can be seen that the majority (65%) have not even completed their primary education. However by creating awareness and imparting the definite skill sets in women entrepreneurs, restored self confidence in them to set up their units. Women who have completed primary education are coming forward to take technical training and establish their units (23%).

Counseling by JSS helped many aspiring women to identify different opportunities available for them. The necessary information, tools and support services provided by JSS made them achieve their goals i.e. to establish the unit.

| Particulars | Number |
|-------------|--------|
| Married     | 67     |
| Unmarried   | 33     |
| Total       | 100    |

**Table No.III: Marital Status of women entrepreneurs**

It can be observed from Table No.III that unmarried women constitute 33% of total respondents, which would mean that women would like to have economic independence before they go for marriage. In other words they realized the importance of economic empowerment of women. We can conclude from Table No.III that irrespective of marital status, women are venturing into self employment units.

| Particulars         | Number |
|---------------------|--------|
| Schedule Caste (SC) | 28     |
| Schedule Tribe (ST) | 2      |
| Backward Caste (BC) | 23     |
| Minorities          | 33     |
| Others              | 14     |
|                     | 100    |

**Table No.IV: Different Categories in the society and number of women entrepreneurs**

Table No.IV gives the details of minority women who consist of 33% of the total respondents which is again a welcoming sign for the society. Even the oppressed class of society like SC (28%), ST (3%) and BC (23%), women are coming forward to empower themselves by taking initiative in starting their own units. We can infer that JSS is encouraging women belonging to oppressed class (86%) of the society.

|                    |                           |
|--------------------|---------------------------|
| Activities         | Activities                |
| Tailoring          | Saree rolling             |
| Chemical products  | Making Chocolates         |
| Computer and DTP   | Fashion designing         |
| Screening printing | Beautician courses        |
| Making perfumes    | Making Juices and Jellies |
| Neem seed powder   | Fabric painting           |
| Leaf Plate         | Cloth bag making          |
| Vermi Compose      | Weaning                   |

**Table No.V: Activities in which women entrepreneurs were involved.**

The Entrepreneur Development Program (E.D.P) is designed to suit local people, identifying local resource, product and technology. E.D.P. is given short term and long duration also, after the training guidance to start the enterprise by awareness camps, interaction with other W.E. etc.

In imparting the skill set seen in Table No.V, majority of the women initially were interested in Tailoring (50%), saree rolling (20%) and beautician courses (10%). But now they are interested in building their skills in computer and DTP, Fashion Designing, Chemical products etc.

| Particulars        | Number | Particulars               | Number |
|--------------------|--------|---------------------------|--------|
| Tailoring          | 29     | Saree rolling             | 12     |
| Chemical products  | 12     | Making Chocolates         | 4      |
| Computer and DTP   | 6      | Fashion designing         | 4      |
| Screening printing | 2      | Beautician course         | 4      |
| Making perfumes    | 3      | Making juices and jellies | 6      |
| Neem seed powder   | 2      | Fabric painting           | 2      |
| Leaf Plate         | 6      | Cloth bag making          | 3      |
| Vermin Compose     | 3      | Weaning                   | 5      |

**Table No.VI: Unit setup in different activities.**

Table No.VI shows the unit setup's in different activities and how they converted their skills into income generating activities. We find majority of the women (29%) started their units in tailoring and saree rolling (12%), along with traditional units (12%) chemical products (12%), chocolate making (4%), computer and DTP (6%) etc. which means women could start units in different and varied activities and also in beautician courses (4%), making perfumes, making juices and jelly (6%), making leaf plates (6%), bag making (3%), vermin compose (3%), weaning (5%). Etc.

| Investment (Rupees) | Number |
|---------------------|--------|
| Below 1000          | 42     |
| Up to 2000          | 27     |
| Up to 3000          | 11     |
| Up to 4000          | 12     |
| Above 5000          | 8      |
| Total               | 100    |

**Table No.VII: Investment**

Table No.VII shows the investment made by the respondents for their respective units. Majority of the units were started with low investments ranging from Rs.1000 (42%) to

around Rs.2000 (27%), few in the range of Rs.3000 to Rs.4000 around (23%) and very few above Rs.5000 (8%). This is convenient for them to raise the finance on their own. Slowly they can expand the unit with retained earnings. Few of them (12%) have taken the help of JSS to raise the loan from banks.

| Income Earned (Rupees) | Number |
|------------------------|--------|
| 500-1000               | 43     |
| 1000-2000              | 21     |
| 2000-3000              | 16     |
| 3000-5000              | 12     |
| Above 5000             | 8      |
| Total                  | 100    |

**Table No.VIII: Income Earned**

Table No.VIII gives the income earned by the respondents from their units. It can be seen that the income earned by the self employed women is reasonable compared to their investment and other constraints like working from home and utilizing their leisure time.

Majority (43%) of them are getting up to Rs.1000, (21%) are getting around Rs.2000 and (16%) are able to earn Rs.3000 and 12% of them could earn up to Rs.5000. Few of them (8%) could earn Rs.5000 from making chocolates, bag making, tailoring, perfume manufacturing units.

The income earned by the WE is encouraging (i.e. Rs.1000 to Rs.5000) compared to their investment on an average. The unit initial investment is recovered within couple of months, which also contributes for their capital and hence expansion.

| S.No. | Particulars   | Strongly Agree | Agree | Don't Agree | Disagree | Strongly Disagree |
|-------|---|----------------|-------|-------------|----------|-------------------|
| 1.    | Is there any considerable change in the family – after setting the unit     | 12             | 60    | 20          | 8        |                   |
| 2.    | Is there a change in the personal front – does the family have high regards | 12             | 60    | 20          | 8        |                   |
| 3.    | Do you have much more importance in the family now                          | 15             | 70    | 15          |          |                   |
| 4.    | Do you have much more say in the decision making in the family              | 8              | 65    | 12          | 15       |                   |
| 5.    | Do you have self satisfaction for your earnings                             | 15             | 85    |             |          |                   |
| 6.    | Does your earnings has boosted your morale                                  | 10             | 80    | 10          |          |                   |
|       | <b>Society Level</b>  |                |       |             |          |                   |

|    |  |   |     |    |    |    |
|----|--|---|-----|----|----|----|
| 1. | Is there any considerable change in the social status for you        | - | 80  | 10 | 10 |    |
| 2. | Is the society accepting women emancipates through entrepreneurship  | 5 | 92  | 3  |    |    |
| 3. | Do you feel you have acquired some leadership qualities              | 8 | 60  | 20 | 12 |    |
| 4. | Do you advice other women to start similar activity                  |   | 100 |    |    |    |
| 5. | Do you think JSS has brought positive change in you                  |   | 100 |    |    |    |
| 6. | Do you believe given an opportunity women can achieve what they want | 9 | 60  | 1  | 10 | 10 |

**Table No.IX: Likert – Five Point Scale**

Likert five point scale is used to measure the women emancipation at individual level and change in her status and quality of life at societal level.

Table No.IX shows majority of women (60%) agreeing with the fact that there is considerable change in the family after starting their unit.

When asked about change in their personal front again same number of women (60%) expressed that they agree that family members have high regard for them now.

Majority of the women (70%) agree now that they are given much more importance in the family and a majority (65) of the respondents said that even their importance is increased in making family decisions due to their unit.

When enquired about their satisfaction level due to their earnings, (85%) majority agreed and 15% strongly agreed for the same.

10% strongly agreed that the earnings boosted their morale and 80% agreed and 10% of them said they don't know.

When women entrepreneurs were questioned regarding their social status and changing quality of life, 80% of the women agreed that there social status has increased but 10% each said they disagree and they don't know.

When asked whether society accepts women emancipation through entrepreneurship, a majority (92%) of respondents agreed and 5% strongly agreed and 3% of the respondents didn't know.

60% of women respondents agreed that they have acquired leadership qualities through JSS, however 32% together said they disagree.

100% respondents wanted to encourage other women to start similar income generating activity.

100% of Women respondents believed that there is positive change towards life due to JSS only.

69% of the respondents felt women can achieve anything, given an opportunity, however 31% respondents opinion is differing with this.

## **CONCLUSION**

A comparison of women before and after undergoing the JSS training program showed that the WE, after the training, were much more confident and willing to accept new challenges, and explore other avenues to generate income.

At a societal level, WE who established their units gained immense respect, enjoyed a higher social status, and exercised far greater economic freedom.

In a man-made world, these women have set their standards. By being self-reliant, they are living their expectations, and more. They inspire other women to join in this revolution to attain women emancipation. The women need 'Life Enrichment Education', creating self-confidence, and the ability to think, act and live independently.

Today, given an opportunity, women are more than willing to seek new opportunities, accept tougher challenges, and constantly strive to improve their surroundings. This need to prove themselves must be recognized by the government and other non-governmental organizations, and all efforts must be directed towards entrepreneurship, which in turn contributes towards the social and economic development of a country.

The JSS training program to create awareness, build self-confidence and self-reliance has brought about a positive change in the attitudes of the oppressed women belonging to a lower income and status group in India. Strong evidence now exists to prove that emancipation of women is more successful and attainable through entrepreneurship.

Additional training to improve literacy through short-term courses, monitoring of women owned units for a period of 2 to 3 years to overcome initial problems also needs to be provided. Taking the trained women to visit other units, and arranging for meetings between successful WE and those about to set up a new unit, adds to the enrichment of women. It is also important to maintain a database of women-owned units, create counseling centers at convenient locations, and finance units run by women at low

interest rates. Help in the marketing of products through government agencies by making it mandatory to buy 50% from women-owned units go a long way in encouraging more women to join such programs as those run by JSS.

It is only when the upliftment of a woman takes place that the women move forward, then the family moves, the village moves and the nation's economy moves.

## **The Entrepreneurial S-Curve: A Conceptual Model for Entrepreneurial Life Cycle**

### **Abstract**

We develop an entrepreneurial S-curve (ENT S-curve) to describe the trajectory of the entrepreneurial process. We examine specific risks involved at each stage of the entrepreneurial process, and propose a strategic model to manage the risks occurring during the lifecycle of the ENT S-curve. The ENT S-curve is a useful predictive tool for entrepreneurs to perceive the trajectory of the entrepreneurial process. The ENT S-curve is developed from theoretical analysis based on the technological S-curve and examples of previous entrepreneurial startup ventures. The ENT S-curve provides a conceptual tool for entrepreneurs to conduct appropriate preparation and formulation of strategies to achieve higher performance and economic benefits. Moreover, venture capitalists may use the ENT S-curve to forecast the possible managerial tasks and solutions required for the venture, to formulate exit strategies, and/or to determine capital injection time frame.

## Introduction

Many scholars and researchers have examined entrepreneurial traits, behaviours, outcomes, and processes. However, most of the work on entrepreneurial processes has been piecemeal, focusing only on certain aspects, including conceiving and directing vision; financing the enterprise; planning expansion, growth, and competitive market strategies; managing resources; building social, ethical, and international networks; and examining firm boundaries and exit strategies (e.g., Johanson & Mattson, 1988; Coviello & Munro, 1995; Hakansson & Snehota, 1995; Keeble, Lawson, Smith, Moore, & Wilkison, 1998; Russel, 1999; Dana, Etemad, & Wright, 2000; Etemad, Wright & Dana, 2001; Rasmussen, Madsen, & Evangelista, 2001; Jones & Conway, 2004). However, a single, holistic model to help entrepreneurs conceptualize the entire entrepreneurial process has not yet been devised.

This paper describes the entrepreneurial process as a single, curved line, the *entrepreneurial S-curve*, characterizing the critical stages in the entrepreneurial process. The concept of the entrepreneurial S-curve is intended to help entrepreneurs predict, formulate, and execute strategies over time, taking into account changes in context.

In this paper we describe the conceptualized entrepreneurial S-curve with three stages in the entrepreneurial process as well as possible and relevant risks along each stage—the entrepreneurial risk model. We then discuss the critical elements as tools—the entrepreneurial fit models—that may be helpful for entrepreneurs to manage those stage-related risks. Finally, we correlate the entrepreneurial S-curve, entrepreneurial risks, and the fit models together, and suggest a future research agenda and three propositions.

### Development of the entrepreneurial S-curve

The concept of the S-curve has been used in several areas of business studies: the technological S-curve is a visual expression of the adoption rate of technological innovation and the innovation diffusion process (Sahal, 1981; Henderson & Clark, 1990; West, 1992; Martin, 1994; Levinthal, 1997), and international diversification and firm performance (Lu & Beamish, 2004). Product lifecycle and firm lifecycle are also described in terms of an S-shaped curve. In this paper, the S-curve represents the changes that occur over time during as the entrepreneurial process unfolds.

We identify three stages in the entrepreneurial processes: startup, high growth, and sustainability (Roberts, 1999). We do not include the global enterprise stage because some firms expand internationally at inception, a phenomenon known as “born global” (McDougall & Oviatt, 1995, 2000). Thus, we treat internationalization as a strategic move instead of a stage in the entrepreneurial process. For the three stages of entrepreneurial processes, we identify problems in terms of specific risk (Barrow, 1981) involved at that stage, and introduce appropriate tools (Roberts, 1999; Stevenson, 1999) to manage the risks. All of the risks (e.g., developmental, manufacturing, marketing, management, growth, and public finance risk) may occur at all three stages (J. Webster, university lecture, February 19, 2004). This paper, therefore, attempts to

focus on those risks that are most prominent at specific stages of the three-stage entrepreneurial process.

### **Entrepreneurial Process Development: the three stages**

We define the entrepreneurial process as one involving a business idea at the inception of a startup, opportunity identification, business plan preparation, startup strategy development, growth management, innovation management processes, and so forth over the life of an entrepreneurial firm. We do not include firms that intend to remain small. Hence, the entrepreneurial process is further defined to include a startup stage, a high growth stage, and a sustainability stage. The entrepreneurial process is not confined to these three stages, since the process evolves in relation to other factors, such as products/services/business extension or geographical extension.

During the sustainability stage, entrepreneurs extend the venture's success by preparing for development of new products, services, or business processes, or planning for internationalization that would lead to new opportunities, resulting in the formation of a new curve on the chart. This new curve represents startup, high growth, and sustainability stages, and the beginning of an ever-evolving process.

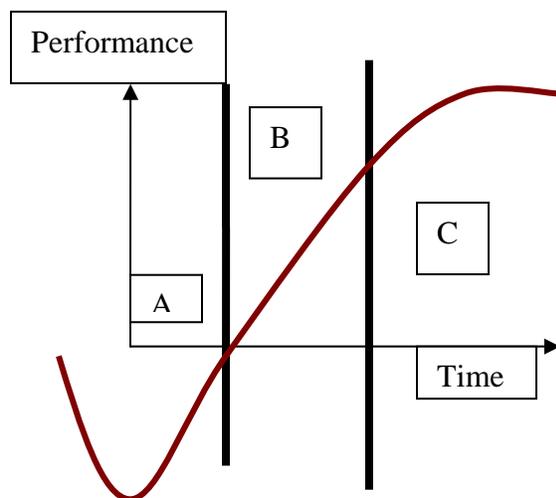

Figure 1: The entrepreneurial S-curve illustrates the three stages of the entrepreneurial process: (A) startup, (B) high growth, and (C) sustainability.

In the *startup stage*, entrepreneurs invest time and human and financial capital in the venture. The financial capital of the startup is derived from the entrepreneur's own savings, "love funds" provided by friends and family, or investments by venture capitalists. This upfront investment is a sunk cost at the startup stage, and the capital outlay can only be realized at a later stage. Thus, the curve in the startup stage (see "A" in Figure 1) is in negative territory. If the startup venture is successful and breaks even early on, investors can recoup their investment sooner. Sometimes entrepreneurial ventures, especially in biotechnology, high technology, or industries requiring a great deal of research and development, do not reach breakeven point for a long period of time, and gains on investment are delayed.

In the *high growth stage* (see “B” in Figure 1), the curve ascends steeply. This is where the learning curve changes significantly as the entrepreneurial venture grows either from market pull or competence push. Market pull is the result of high demand for certain products, general economic growth, or industry specific growth. Competence pull relates to the core competence of the venture and entails an accumulation of experience and specific human or financial capital over time. This is the stage where learning is rapid and productivity and profitability are at their highest levels. At this stage, entrepreneurs need to have the managerial mind-set and skills to take advantage of the possible profit and growth. If they fail to move from entrepreneurial mind- and skills-set, the venture could lose on many fronts (Stevenson, 1999).

The *sustainability stage* (see “C” in Figure 1) of the entrepreneurial process is characterized by slow growth. If entrepreneurs lack anticipating, acting, and reviewing techniques that are essential for managers and leaders at this stage, the survivability of the venture might be in doubt (Roberts, 1999). The venture could plateau and then take a downturn. At this stage, supreme managerial skills are required to manage incremental and radical change (Stevenson, 1999).

One of the major reasons for startup failure is lack of managerial skills. Both the high growth and sustainability stages require entrepreneurs to transform their mind- and skills-sets from entrepreneurial to managerial skills. Stevenson (1999) argues that as the venture grows, a formal organizational structure is required. Thus, administrative behaviour is preferred in terms of strategy orientation, commitment to opportunity, commitment to resources, management structure, and reward systems. At the same time, it is important for firms to sustain growth with entrepreneurial spirit and innovativeness so that the “overlapping” of entrepreneurial and managerial behaviour is essential (Stevenson, 1999).

### **Entrepreneurial Risk: The six risks**

There are many risks involved in managing a venture. Focus here is on six critical risks that are involved in an entrepreneurial process (Barrow, 1981): developmental, manufacturing, marketing, management, growth, and public finance. These risks occur at all three stages of the entrepreneurial process (J. Webster, university lecture, February 19, 2004). However, certain risks are more prevalent at certain stages. For example, both developmental and manufacturing risks are higher than growth and public finance risk at the startup stage.

We define each of the six critical risks in the entrepreneurial process as follows:

**Developmental risk:** Deals with the product or service that must meet intended/required specification at the developmental stage of the product or services. This involves the risk in the development of optimal use of opportunity and resources such as technology, human capital, and financial capital. Prior to launching a product or service, this is a critical risk.

**Manufacturing risk:** Involves bargaining with suppliers, raw materials management, sole supplier risk, and risk in management of production, outsourcing, and in-sourcing.

Marketing risk: Involves the possibility that a competitor will launch a similar product, the loss of first mover advantage, technology changes, product obsolescence, advertising and pricing wars, legal, regulation, and environmental risk.

Management risk: Lacking the capability to manage, retention of employees, human capital risk, internal risk to the firm, risk due to lack of managerial and leadership skills.

Growth risk: Risk in managing growth, retaining employees, putting organizational structure in place when dealing with growth, setting up reward systems, and having sufficient finances to deal with growth.

Public financial risk: Involves management of the IPO process pricing issues, public relations, managing external expectations (see Figure 2).

The following table illustrates risks that are involved at every stage, but that increase at particular stages.

| <b>Stage/ENT risk</b>        | <b>Startup Stage</b> | <b>Hi-growth Stage</b> | <b>Sustainability Stage</b> |
|------------------------------|----------------------|------------------------|-----------------------------|
| <b>Developmental Risk</b>    | More                 | Less                   | Less                        |
| <b>Manufacturing Risk</b>    | More                 | Less                   | Less                        |
| <b>Marketing Risk</b>        | Less                 | More                   | Less                        |
| <b>Management Risk</b>       | Less                 | More                   | Less                        |
| <b>Growth Risk</b>           | Less                 | Less                   | More                        |
| <b>Public Financing Risk</b> | Less                 | Less                   | More                        |

Table 1: Three stages in the entrepreneurial process and comparative risk at each.

Entrepreneurship is plagued with risks, which should be dealt with early on to ensure the venture stays viable. The concept of the six critical risks along the entrepreneurial S-curve provides a strategic tool for startup firms to map out the risks that can affect the company vis-à-vis its operations, employees, stakeholders, and customers (see figure 2).

Risks are apparent from the beginning of a business's development to the last stages of its lifecycle. The S-curve concept allows startups to forecast risks so that contingency and strategic plans may be formulated to prepare for strategies execution.

When starting a venture, there is always the possibility of developmental risk since the initial stages of development carry a heavy burden of expenses and a deep initial investment (see figure 2). Being able to carefully manage operations can help the process of entrepreneurial development while managing risks accordingly. Risks are also possible in the manufacturing process of a business venture. Risks regarding supplier partnerships and the manufacturing

process are prevalent in most businesses and should be noted so that contingency plans can be made to avoid future problems.

As with any business, management risks exist at all stages within the development cycle. Marketing risks play an important role during the development of an entrepreneurial venture, and effective advertising and proper public relations are crucially important. As a business begins to grow and expand, so do the risks involved. Rapid growth, if not properly managed, could potentially cause the company to spin out of control. Finally, good financial management in terms of public offerings is essential to an expanding venture in overcoming the risks involved in obtaining financing. Sound plans and strategies must be created to manage risk during the entrepreneurial process; it is important to identify the major risk areas, formulate strategies, and prepare for successful execution to achieve and sustain economic success.

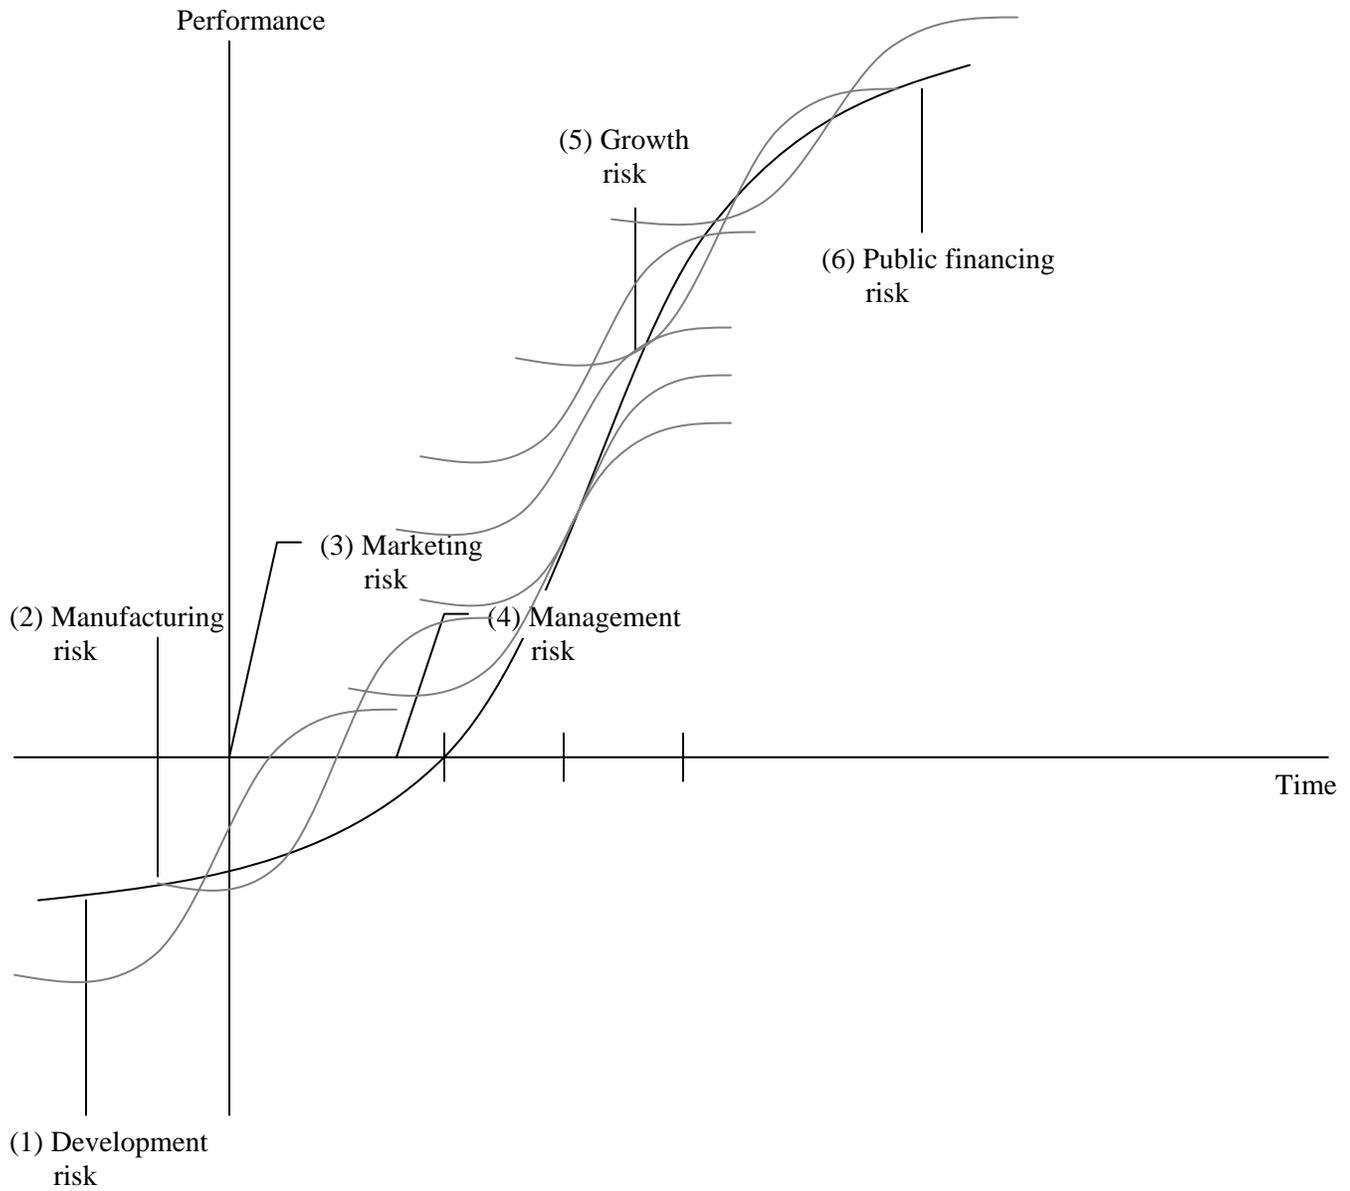

Figure 2: Six critical risks along the entrepreneurial S-curve: Overlapping curves occur because each type of risk can occur at any point in time during the entrepreneurial process.

**Entrepreneurial Fit Model: elements in the Four Fit Models**

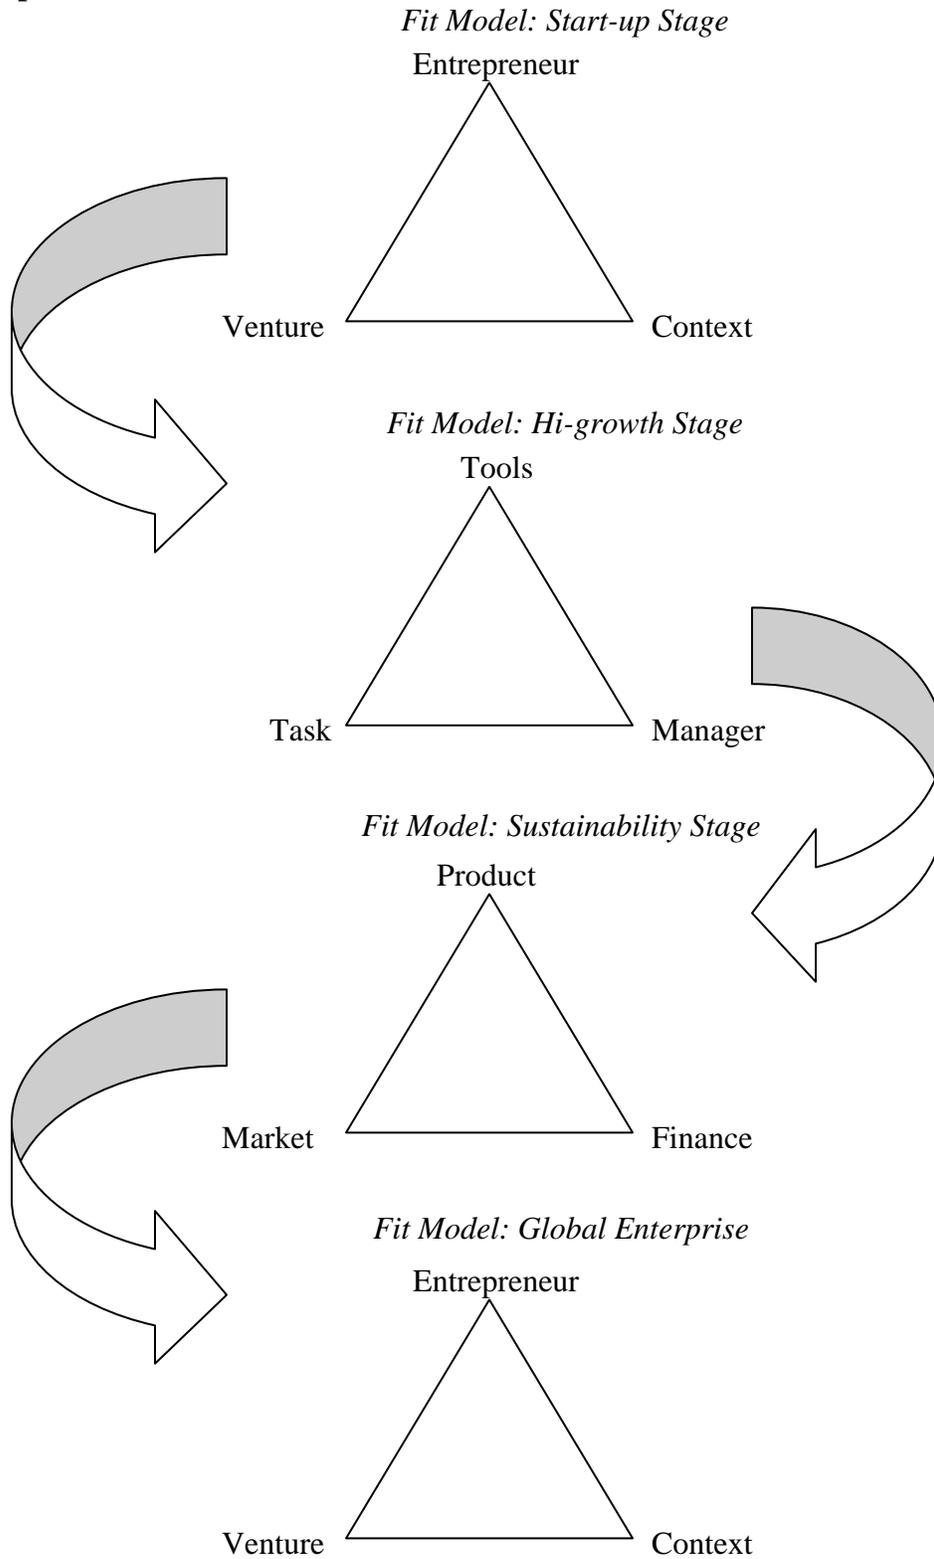

Figure 3: Critical elements of the FIT Model in various stages of entrepreneurial process.

| <b>Stage/Tool (Fit Model)</b>                     | <b>Startup Stage</b>           | <b>Hi-growth Stage</b> | <b>Sustainability Stage</b> |
|---|--------------------------------|------------------------|-----------------------------|
| <b>Elements in Startup Stage Fit model</b>        | Entrepreneur, Venture, Context |                        |                             |
| <b>Elements in Hi-growth Stage Fit model</b>      |                                | Tools, Tasks, Manager  |                             |
| <b>Elements in Sustainability Stage Fit model</b> |                                |                        | Product, Market, Finance    |

Table 2: Three stages along the entrepreneurial S-curve and the specific *fit model* for each stage

Ardichvilia, Cardozob, and Rayc (2003) explain that the venture development process is a cyclical and iterative one. As a venture grows, entrepreneurs must learn to adapt to all changes in order to survive. As the firm expands, continuous evaluations and projections are required to forecast and predict future strategic moves. The Four Stages – Fit Models (See Figure 3) may be used by entrepreneurs to plot the various stages of an entrepreneurial life cycle.

Roberts (1999) suggests that there are four stages involved in corporate venturing: (1) Start-up, (2) Hi-growth, (3) Sustainability, and (4) Global Enterprise. We treat the last stage as a strategic move, a decision to expand internationally at inception or at a later stage (McDougall & Oviatt, 1991). The global enterprise fit model is included here to illustrate that when a venture expands internationally, it must restart; thus, the elements in this model correspond with the conditions prevailing at startup stage.

Each stage in the entrepreneurial process involves three correlating and critical elements that must fit together to achieve success at that stage (Roberts, 1999). This tool works as a cyclical model as it can be used at all levels of a firm’s entrepreneurial development. During the startup stage of the entrepreneurial process, the Start-up Fit Model accounts for the (1) venture, (2) entrepreneur(s), and (3) context. The entrepreneur(s) conducting the business should match the venture initiative to the market needs/wants of the current time period. If the context of the business needs to be realigned to satisfy the needs of consumers, then the venture should be adjusted to fit the new initiatives, and the entrepreneurs should have the drive to re-formulate the business model.

Following the achievement of the elements set out in the Fit Model at the start-up stage, the Fit Model in the high growth stage is comprised of (1) tools, (2) task, and (3) manager. As a venture begins to grow and expand, strategic tools need to be developed to structure the growth of the business while tasks are built/developed for the venture. It is then the manager’s responsibility to administer and delegate tasks to subordinates while ensuring that proper tools are used to streamline operations.

Eventually, the rapid growth cycle of a business will begin to plateau, during which the Sustainability stage Fit Model and its elements of (1) product, (2) market, and (3) finance should be taken into consideration. It is important for the venture to commit to continuous improvement in its products/services/business processes to sustain its viability. Funding is also required when developing innovations and should be managed appropriately to achieve sustainability. Ardichivilia et al (2003) argue that entrepreneurial development involves three distinct processes: (1) sensing or perceiving market needs or underemployed resources, (2) recognizing or discovering a “fit” between particular market needs and specified resources, and (3) creating a new “fit” between separate needs and resources in the form of a business concept. This concept echoes our Fit Model and its four stages. Both analogies strive to portray that a sense of “fit” is needed between all elements for a venture to achieve and sustain economic success. Each stage of the entrepreneurial process involves some form of change and with that, the elements involved within the Fit Models also need to be adjusted. This proves that the entrepreneurial process is both cyclical and iterative.

### **Entrepreneurial S-Curve: S-curve, risk and fit model correlation**

The correlation between the Fit Models and entrepreneurial risks can be noted here to formulate a cycle along the entrepreneurial process. As the two approaches join, we can see that elements within the Start-up Fit Model relate to the early stages of an entrepreneur’s journey. Once the initial investment and the payback period has been achieved, a firm may begin to experience rapid growth and expansion. Using the tools provided by the Hi-growth Fit Model, managers can ensure that the organization has the potential to continue to develop into a larger business venture. Businesses at some point usually enter into a period of stagnation (commonly following a period of rapid growth). During this phase, managers of a firm may profit from an understanding of the sustainability phase and its elements of product, market, and finance to keep its operations viable. This conceptual framework may allow entrepreneurs, corporate leaders, and venture capitalists to better understand their own businesses and forecast potential risks and opportunities, thereby formulating plans to avoid obstacles, seize opportunities, and achieve new heights.

### **Implications**

Entrepreneurship is developed when an individual seeks and discovers an opportunity that is presented from within the economy and acts to take advantage of it (Holcombe, 2003). Entrepreneurial skills, tools, and frameworks can be learned and used. The entrepreneurial process begins when individuals or corporations commercialize core competencies that results in energized economic development. Entrepreneurial process involves two sets of skills: soft elements and hard elements. Soft elements cannot be learned because they include the components of vision, mission, and passion. Hard elements comprise skills that can be acquired, some of which include marketing, finance, human resources, networking, negotiation, presentation, and managerial skills. It is our belief that entrepreneurs and managers already possess vision, mission, and passion for their venture. However, many might not have hard skills before they started their ventures. Our research agenda aims to identify and examine the theoretical framework discussed above—the entrepreneurial S-curve that demonstrates changes in the entrepreneurial process and changes in context over time. In addition, we intend to

determine whether the concept of entrepreneurial risks and the entrepreneurial Fit Model, following the entrepreneurial S-curve, might help entrepreneurs to overcome challenges and formulate strategies to achieve and sustain economic success.

### **Conclusion**

In this paper, we proposed and discussed a conceptual model: the entrepreneurial S-curve that aims to help entrepreneurs better understand the entrepreneurial process.

The entrepreneurial S-curve describes the trajectory of the entrepreneurial process and allows exploration of specific risks involved in each stage and strategic models to manage these risks. We argued that the entrepreneurial S-curve is a useful predictive tool for entrepreneurs to perceive the trajectory of the entrepreneurial process. The entrepreneurial S-curve provides a conceptual tool for entrepreneurs to conduct appropriate preparation and formulation of strategies to achieve higher performance and economic benefits. Moreover, venture capitalists may use the entrepreneurial S-curve to formulate their investment strategies vis-a-vis forecasting managerial tasks and solutions required, formulating exit strategies accordingly, and determining appropriate time frame for future capital investment.

## ABSTRACT

Increasing attention is being directed at the concept of work-life balance, with the often espoused benefits including improved retention rates and increased productivity. However, a significant problem with the concept is that much of the discourse is built on a language and logic based in traditional models of large bureaucratic organisations. In the small and medium enterprises (SMEs) the traditional boundaries of work and life are, more often than not, blurred. In this paper the authors challenge existing accepted rhetoric of 'work-life balance' for its appropriateness in understanding how SME owner-managers choose to manage their personal and business lives. The importance of a sense of balance is not disputed; instead the idea that it can be achieved/managed as a sort of equilibrium is

contested. A study was conducted by a team of researchers who used the business life-cycle as a framework for examining the firm's life-cycle and identifying the points at which they made decisions about key 'transitions' between one phase to another. The results revealed that several constraints were identified by SME owner-managers that defy stereotypical notions of work-life balance. A framework is presented for analysing the relationship between personal and business constraints the SME owner-manager faces and the subsequent situations of 'balance' and 'imbalance' that can occur. Finally the authors stress that in challenging the popular discourse of work-life balance it is clear that new discourses are needed for the SME context.

### **INTRODUCTION - IN PURSUIT OF BALANCE**

In New Zealand significant attention has been given in the past two years to the subject of work-life balance. This includes the establishment by Government of a project devoted to developing policies and practices promoting a better balance between paid work and life outside of work. This is congruent with the promotion of work-life balance policies as win-win for both individuals and organisations (Barnett & Hall, 2001) with the often espoused benefits including improved recruitment and retention rates, reductions in worker stress and increased productivity. The link between work-life balance and increased productivity is often used to promote the business case for work-life balance policies. There are several different theories about the connection between work-life balance and productivity. Some argue that policies lead to productivity gains by decreasing negative spill-over from workers' lives and reducing extended hours and fatigue. Other arguments use an exchange framework, suggesting that in return for the 'gift' of work-life balance policies, employees offer the 'gift' of discretionary effort, thereby increasing productivity (Department of Labour, 2004b).

In the work-life balance concept, work and leisure are commonly viewed as dichotomous and antithetical, however a significant problem with the concept according to Caproni (2004) is that much of the discourse of work-life balance is built on a language and logic that are based in traditional models of bureaucratic organisations, and "thus the discourse is likely to perpetuate and perhaps further entrench – many of the problems it promises to alleviate" (p.209). She heralds the importance of using alternative perspectives to ask: What is the current version of reality promoted by the discourse on work-life balance? This is a

particularly relevant question in terms of investigating small and medium enterprises (SMEs) in which the traditional boundaries of work and life are, more often than not, blurred. In SMEs there is often a reciprocal relationship between business success and personal success for the owner-manager. A problem though with current definitions of work-life balance, as Van Eijnatten & Vos (2002) explicate is that the predominate focus is on the perspective of individuals, whereas both an organisational and individual perspective is necessary to gain a better understanding of difficulties in addressing work-life balance related problems.

The purpose of this paper is to challenge existing accepted rhetoric of 'work-life balance' for its appropriateness in understanding how SME owners choose to manage their personal and business life. It is important to clarify that we are not disputing the importance of a sense of balance; instead we challenge the idea that it can be achieved/managed as a sort of equilibrium. The rhetoric of work-life balance is problematic for the SME sector due to the significant personal and business constraints facing operators in this context.

## **WORK-LIFE BALANCE AND SMES**

Although there is an ever-increasing body of literature on work-life balance, it is evident that studies vary in what is specifically investigated, for example flexibility versus work-family policies. This results in many of the conclusions being context specific and not necessarily generalisable. As a result, concepts related to work-life balance remain theoretically cloudy and empirically ill-defined (Felstead, Jewson, Phizackles & Walters, 2002). It is not surprising that there is a dearth of literature about the business case for work-life balance for SMEs. This is partly because work-life balance policies in this context are generally informal and individually negotiated making them difficult to pick up in surveys, but also because the presence of work-life balance policies is often correlated with businesses larger in size (Galinsky & Bond, 1998). As Evans (2001) found, in general, work-life balance policies are more likely to be reported in large firms in Australia, Japan, the UK and the US. In New Zealand, the results of case study research conducted by UMR Research for the Government's Work-Life Balance project showed that the firm size appeared to determine the attitude towards work-life balance among respondents. The research highlighted that for "small employers, initiatives were likely to be viewed as expensive and difficult to

implement, while medium-large employers were more likely to have many of the initiatives already in place” (Department of Labour, 2004a, p.37).

Aside from the ‘fuzzy’ definitions of work-life balance, another problem when investigating such issues in SMEs is the variability in accepted understanding of SME size which differs between and within countries. In the US the definition of SMEs is industry specific, meaning in some cases firms with up to 500 employees could be classified as small businesses (Small Business Administration, 2004). In the UK, Department of Trade and Industry usually uses the definitions of a micro firm having 0 - 9 employees, a small firm having 10 - 49 employees, a medium firm having 50 - 249 employees and a large firm having over 250 employees (Small Business Service, 2004). Even within New Zealand, leading academics Cameron and Massey’s (1999) definition of micro business as having fewer than five employees, a small business as six to 49 employees and a medium business as having between 50 and 99 employees is at odds with the New Zealand Government’s definition of a SME as having fewer than 20 employees (Ministry of Economic Development, 2004). The problem with such variability in SME size for researching work-life balance policies is that we may not be comparing ‘apples with apples’. For example the management structures and financial resources available for strategies of flexibility in a business of 170 staff will be in a completely different league to that of a business with seven staff.

In endeavouring to establish the cumulative body of knowledge on work-life balance, a literature reviewed conducted by the New Zealand Department of Labour (2004b) concluded that there is substantial debate about the ease with which SMEs can implement more traditional work-life balance policies particularly in terms of flexibility of hours and even about the wider business case for work-life balance policies in SMEs. One train of thought is that SMEs have certain advantages in implementing flexible policies as it is probably easier for such businesses to undertake internal reorganisation due to less role specialisation and the need for staff to be able to multitask.

On the contrary, is the argument that work-life balance policies are often correlated with luxury domain of larger businesses, with costs being often perceived as too significant for the SME and that smaller organisations have fewer staff to cover for each other. Interestingly Roper, Cunningham and James (2002) found in their study of attitudes of British human resource specialists in firms of with 20 employees that opposition to the idea of work-life

balance legalisation, based on the perceived negative impact of the policies, was higher than opposition based on principles. Another reason found for employers being less convinced by the business case for work-life balance is that worker productivity is easier to monitor in an SME. A further explanation for the irrelevance of formal work-life balance policies for SMEs that has been proposed is that employees and employers in SMEs are much more likely to have informal relationships based on trust and giving (Evans, 2001). The validity of these arguments for SMEs will differ depending on the personal choices made by the owner-manager for their firm in regard to work intensity, the nature of the business, number of staff, hours of operation and flexibility in capacity, schedules and service levels.

Personal choice of the SME owner-manager to construct their lives in terms of fit of the various facets including work, family, leisure, and rest is significant in terms of having power over the moderating factors limiting work life balance that workers in larger organisations face. As Ghazi (2003) states, “it is not necessarily about working less, rather about having personal control and flexibility over when, where and how we work (p.xiii). As Walker and Brown (2004) explain, the motivation for people to go into small business is varied, and includes financial as well as non-financial factors like personal satisfaction, independence and flexibility. In her study of women entrepreneurs in Canada, Fenwick (2002) found that many of women said they started a business because they longed for more freedom and control over their lives; “freedom that brought complete and perpetual responsibility for one’s decisions” (p.712).

Rather than traditional notions of balance, discourses emphasising health may hold more appeal for SME owner-managers. Higher levels of job demand, longer working hours and less time for leisure activities appear to be characteristics of those who are responsible for their own success (Chay, 1993). The literature on stress management emphasises the importance of locus of control and social support in influencing stress and strain and the stress-strain relationship (Rahim, 1996). Entrepreneurs are often reported as possessing a higher internal locus of control than managers. There is a fine balance though between extreme drive and health, it is generally believed workaholics tend to deny the existence of fatigue and push themselves beyond reason before physical complaints stop them working (Kanai, Wakabayashi & Fling, 1996). However others in the field also caution that the empirical data on workaholism is scant and contradictory (Burke, 2000; McMillan & O’Driscoll, 2004). Attention must be given to issues of sustainability of momentum and

energy, particularly through preservation of owner health, as the consequences of a sustained lack of balance are aligned with health problems including heart problems, high blood pressure, gastrointestinal disorders, psychological well-being and circadian disruption (Department of Labour, 2004b).

Given the dearth of literature, polarised opinion on the complexity of work-life balance policies for SMEs, and SME owner-manager capacity for freedom and choice, the question needs to be asked: Is the rhetoric of work-life balance with its associated assumptions appropriate for thinking about balance in the SME sector? A sector containing a vast array of diverse operators and operations in which the boundaries are unclear, particularly for those perhaps whose businesses are located in their homes? Or for those who work with family? As de Bruin (2004) stresses, the blurring of the boundaries and the way work and life traverse are not caught at all through the metaphor of the work-life balance. An alternative metaphor from balancing time is given by Thompson and Bunderson (2001) who conceived time as a 'container of meaning' thus allowing "us to address of the nature of the activities that occupy our time, including the significance that they assume" (p.18) which as a metaphor could hold more attraction for the SME sector rather than one striving for equilibrium between work and leisure, metaphors such as work-life balance, work/family borders, and work and non-work conflict.

Beatty and Torbert (2003) posit that work and leisure are complements that in their highest states share core elements and are best understood in dynamic relation to each other. Self-employed individuals negotiate multiple discourses and identities among which competitive individualism is not the most dominant (Fenwick, 2002). This is fundamental when challenging traditional notions of work-life balance that have been built within large organisations in which workers often have less power, freedom and personal choice in regard to construction of their work and indicators of success within those structures. Most small businesses are the products of their owners, whose personality and personal involvement dominate (Mazzarol, 2003). Many small business owner-managers are motivated by factors other than a desire for growth (O'Farrell & Hitchens, 1988) and thus may already have built many of the traditional balance ideals such as flexibility and downtime into their lives.

A review of the literature shows that the body of knowledge on work-life balance is still in an emergent state. Furthermore there is a clear lack of understanding of the work-life balance

concept in regard to SMEs. This paper aims to make a contribution to building such understanding. While the initial focus of our study was not to specifically focus on work-life balance in SMEs, we gained substantial data to build a case for theorisation about work-life balance in this context.

## **RESEARCH APPROACH**

A project team of eight researchers conducted interviews with 50 firms located throughout New Zealand. These firms were recruited from a random sample of 500 New Zealand firms employing fewer than 50 full-time staff (drawn from a commercial database). Given the aims to the research, a qualitative methodology was designed. Each firm was visited by a member of the research team and the owner or manager was taken through a semi-structured interview schedule. During the interview they were asked to identify the key events and/or milestones in the life of the business (with some approximate dates and/or some sense of chronology) and describe their objectives for the firm. Although the project team's main interest was to learn about the key 'transitions' that New Zealand encounter as they attempt to grow, and how the owners' experiences of these transitions related to the stage models of business growth, the significance of personal events emerged as a key finding. Many of the personal stories we heard of were around events such family, health, especially death, divorce, and disease (Massey, Harris & Lewis, 2004) and the impact this had on the owner(s) and other business stakeholders. Many of these events led the owners to reflect on notions of balance and lifestyle.

## **PERSONAL AND BUSINESS CONSTRAINTS IMPEDING BALANCE**

Several personal and business constraints that defy stereotypical notions of work-life balance were identified by the SME owner-managers we interviewed. We found that many owners are consciously choosing to invest substantial time and energy in their enterprise. It was clear in many cases that such investment was due to their passion for the business as a key part of their life:

*“I enjoy what I do. And I’ve got to the stage in my life where I only do what I enjoy. So I like making castings. I like running the business. We make a reasonable amount of money and I’m as happy as Larry. So, do I want anything more from it? No, not particularly.*

*(Interviewee #4)*

*“...I get out of bed in the morning and enjoy going to work and I guess the day I don’t’ enjoy getting out of bed to go to work will be the day I’ll look at changing things, right at the moment – no every day I love it (interviewee #12)*

Interviewee #21, said with a smile, almost laughing:

*“...it was a hard case, we were just looking at the holidays accrued the other day for looking at the Christmas holiday break and these guys might have 40 – 60 hours, 90 hours of holiday left and I think mine was like 560 hours or something you know, I just haven’t taken any time off really”.*

Working long hours was also frequently described as a matter of personal choice, often correlated with business success, rather than a situation of imbalance from conditions imposed by others needing to be rectified, as is the case in larger organisations:

*“I have gone back to about 65 or 70 hours a week but 100 hours a week was a doddle. And I did that for years and years and years. That’s how small businesses grow, don’t they? On the strength of the owner operator.” (Interviewee #4 ).*

Another common narrative heard was the decision to invest major time and energy into their business in the short-term for long-term lifestyle gains such as early retirement:

*“We don’t want to keep growing and growing and growing and having 20 staff, well I don’t, Dave\* might – we don’t see we’d be doing this for the next 20 years because it’s very long hours and it’s very high pressure you know you can plan to do something as a family and if a client rings and it’s cancelled and Dave\* has to work till midnight five nights running and all weekend so it’s quite high pressure (Interviewee #42) (\*names have been changed to ensure confidentiality).*

Another key issue, intersecting personal and business constraints, is that several owner-managers also possess key skills and knowledge required for operation of the business, expertise that can be difficult and costly to replace.

*“I am the business and I am absolutely aware of that - that if I went away, if I go away for a week its taken me two weeks to plan it. If I go away for four weeks I close the place down... what I carry is the inherent knowledge of the business in my head and I drive it every day myself, which is good and bad, right?” (Interviewee #4).*

The business constraints include the stark reality of limited human resources, with many of the SMEs operating with skeleton staff structures. As a result, many operators were impeded in terms of being able to take time out or away from the business. A typical example of this came from Interviewee #44

*“...when we had more staff he found he could relax a bit more and he could work more in the factory area doing mouldings, now that we have decided to cut back on staff, he works full time from 8 – 4:30 each day, he will go back and work on Saturday’s if it is absolutely necessary but I think as you get older working 7 days a week is not good for you...Your business might be doing good but you could drop dead also because it’s just too stressful, it’s very demanding”*

This was compounded by the commonly held perception of many of the owner-managers that ‘time was money’. Down time, especially for those in service sectors, means less billable hours, so trying for ‘balance’ in terms of having time out, often lead to financial imbalance. A related issue found to quantity of human resources available, was the quality as Interviewee #21 discussed in terms of not wanting to waste his time re-doing work for no charge that was not up to standard:

*“It is exceptionally difficult like our standard is very very high and I have extreme difficulty in tolerating low skill or low effort factor, you know It is like if it’s going to done, it’s going to be done the right way and done properly”*

Interviewee #21 goes on to describes the relationship between producing quality work, customer satisfaction and his personal reputation when talking about lower than desired staff work standards that he has experienced in the past:

*“The attitude of some people is just in today’s world is just unreal and you sort of – it bites at you for two reasons, one is that if it is not up to your standard it reflects on your reputation because whatever is going out of here is basically got our name on the job and the other thing is that you feel is that the customer is paying good money for a second grade type service”*

Concern by the owner-manager for their personal reputation and identity, for example not wanting to let customers down, also emerged as frequent finding. Many of the SMEs were part of networked webs, having close relationships with customers, suppliers etc, therefore keeping the owner-manager very close to their business.

*“Well I was having no time to myself at all because I was starting at 8 in the morning and I wasn’t finished till 5:30 and no lunch break and then the weekends people would ring you up, you’d go out socially, people would come and see you because they had a problem and so you – my whole life was physio, physio the whole time”* (Interviewee #25).

Business demographic characteristics such as the size of the business, the industry sector and location also presented constraints unique to each business. For example, Interviewee #21 spoke of the restrictions of being on call and needing to be accessible to customers often outside of ‘normal’ business hours.

*“... there is a lot of people if you talk to them, a comment I make is yeah I’ve escaped from jail and I’m going home, it’s just like you’re trapped in this system you know you’re on call, because you’re in a retail market, you’ve got to provide a service so you’ve got to respond, that’s what you choose to do but that’s the reality of it, you’ve got to be accessible ...”*

Other common business constraints were related to the constant demands of having your own business in terms of the paperwork; the pressures of ‘working on as well as working in your own business’. Interviewee #45 described his frustrations in running his business during a growth period:

*“We are currently heading for heart attacks if we don’t get more staff soon, I cannot keep up with the demand for this sort of thing especially as a small business because for every three hours we’ve got in here, there’s an hour of bureaucratic nonsense we’ve got to carry on with and it’s really tough for a business, if I stop working I stop earning”.*

Despite the emergence of many personal and business constraints, several interviewees conveyed an awareness of the need for ‘balance’, particularly in regard to working hours, sustainability of health and time with the family:

*“On purpose, I probably do no more than 9 a day, five days a week. Sometimes I’ll work 7 days a week if I have to or all night but on purpose I don’t work, I won’t work anymore than 45 – 50 hours a week because I’ve – in previous job worked 7 days a week, just about killed myself and realised I wasn’t productive” (Interviewee #5)*

*“Yeah there’s a balance, I like the guys to keep a balance but I mean the only other way you can get ahead in life so long as you’ve got to work each day and if they want to get ahead, the work is there for them so they’re not forced”(Interviewee #3)*

Interviewee #8 spoke of described how his fitness and health contributed to him being able to sustain his lifestyle of being able to work a lot harder in the peaks but also pursue his other many passions including family, fishing, and sailing:

*“Yeah I’ve been very fortunate because I’ve had good health all my life, hardly ever get sick, I keep reasonably fit because I’m physically active, I play hard all year around, I sail regularly, I work out at the gym three times a week, I ski hard all winter”*

## **DISCUSSION**

Like many human resource practices when compared with larger organisations, work-life balance policies in SMEs are generally informal and individually negotiated (Dex & Scheibl, 2001). As the various quotes given in the previous section reveal, the opportunities for more traditional balance policies are limited by the many personal and business constraints the

SME owner-manager can face. The personal and business constraints identified from our study are summarised in Table One. It is important to stress that some of the constraints can be conceptualised as both personal and business. The expertise and skill possessed by an individual operator can be conceptualised as both a personal and business constraint. For example, as dentist must be personally present to provide his/her skills their operation is dependent on their skill base. Furthermore industry specific licensing and legislation in such businesses require the 'expert' to be physically present during hours of operation.

---

Insert Table 1 about here

---

While identifying the array of constraints is an important precursor to devising strategies to pursue well-being, it is important to highlight that not all constraints are negative. For example, the 'entrepreneurial personality' - one of drive, great energy, and tenaciousness can be a positive factor for driving business. Moderation is the key though as individuals need to prevent extreme drive leading them to poor health and burnout.

A framework (Figure One) is presented for conceptualising the relationship between personal and business constraints the SME owner-manager faces and how the pressures of, and relationships between, the constraints will predominantly result in a situation of 'imbalance' for them in regard to traditional work-life balance ideals.

---

Insert Figure 1 about here

---

Quadrant A depicts the situation of 'balance' due to low personal constraints and low business constraints. An enviable position for any SME owner-manager; perhaps akin to having found the Holy Grail!

Quadrant B reflects low business constraints, but high personal constraints leading to a situation of 'imbalance'. For example, while the operator may not be the 'resident expert' who has to be physically present for the business to operate, they may choose to work long hours as they have trouble letting others have control in their business.

Quadrant C depicts a situation of 'imbalance' due to high business constraints and low personal constraints. This situation could arise for example in a trade service business that is short staffed and also facing high customer demand thus requiring the staff and owner-manager to work long hours to finish work and maintain revenue levels from billable hours.

Quadrant D is a particularly challenging situation of 'imbalance' due to both high personal and business constraints. Here a range of personal and business constraints will lead the owner-manager to be very close to their business, mentally, physically, and emotionally. While it could be a conscious choice for the owner-manager to be in this situation, and perhaps one they completely enjoy for example during a time of high growth, care must be taken to maintain momentum and passion without tipping the balance into one of obligation, resentment and physical burnout.

Once the owner-manager has acknowledged the quadrant they currently find themselves in, they can also think about the gap between their current and ideal situation, if there is in fact one! Not all constraints are imposed by external parties, nor are they negative. The situations of 'imbalance' (Quadrants B, C and D) according to the more traditional notions of work-life balance, may be in fact be closer to the owner-manager's desired rather than the undesired state; one that they have consciously constructed through their personal and business choices. The framework can influence owner-managers in understanding their unique lifestyle context in terms of how they have integrated their personal drivers and business demands.

The benefit of such a framework is that it acknowledges the inherent problem of the rhetoric of balance and equilibrium underpinning the work-life balance concept. Instead our framework is supported by the reality that lives of SME owner-managers are characterised by 'seasons of intensity' in terms of personal (birth, death, marriage, divorce, health) and business (start up, growth, change, downturn) events. Rather than searching for Holy Grail of balance and equilibrium, the owner-manager can plan strategies to enable them to keep their momentum while retaining their levels of passion, health and success.

We present the framework as a tool that can be used periodically by owner-managers. Movements between quadrants will be expected a logical result of the dynamic and changing nature of personal and business constraints; factors both within and external to the owner-

manager's control. Awareness of where the owner-manager places them self within the framework may encourage them to adopt more of a 'telescope' (proactive), rather than a 'rear view mirror' (reactive) approach to planning for the personal and business 'seasons of intensity' and management of negative constraints.

The framework can also be used by policy makers to contemplate about how populist policies for work-life balance, often formulated and applied in the contest of large organisations, could be problematic for adoption in the SME context. Given the significance of the SME sector in countries such as New Zealand, attention needs to be given to tailoring policies to appeal to SME owner-managers in terms of the constraints they face and personal choices they make.

Given the highly entwined nature of the business and the owner, personal success often equates to business success (Walker & Brown, 2004). In our study the significance of personal events emerged as a key finding when our team set out to learn about the key 'transitions' that New Zealand SME owner-managers encounter as they attempt to grow, and how the owners' experiences of these transitions related to the stage models of business growth. When considering the lifecycle model in regard to the framework, caution should be taken that anecdotal stereotyped groupings are not simply applied, for example, that those in the start up stage will have high personal and business constraints (Quadrant B) whereas those in the maturity stage will have low personal and low business constraints (Quadrant A). The presence of constraints and the relationship between them will be unique to each owner-manager. Cope and Watts (2000) found that while the lifecycle literature provides examples of relatively predictable development crises; their interview data produced extremely diverse and highly individual critical episodes. Nonetheless further investigation of issues of balance at various personal and business lifecycle would be interesting, as Gray (1993) found the personal lifecycle to be a strong influence on attitudes towards growth, with younger respondents tending to be more growth-oriented than older respondents.

## **CONCLUSION**

In challenging the popular discourse of work-life balance it is clear that new discourses are needed when talking about work-life integration in the SME such as that proposed by de

Bruin and Dupuis (2004) of a 'mosaic' in regard to work-life balance and non-standard work. They describe such a metaphor as useful in challenging the discourse of balance, as it can be seen as a combination of pieces, different in size, shape, colour and composition, just as a person's life can comprise of different pieces. Unlike the work-life balance concept the metaphor does not suggest equilibrium. However they also warn though that a problem with this metaphor is that it fails to fully capture both the dynamic context in which the mosaic is located and the evolving nature of an individual worker's networks and relationships.

Irrespective of the rhetoric that is adopted and popularised, whether it is work/life balance, work-life integration, work-life recipe, or life policy, what is vital is recognition that traditional dichotomies in terms of work and life postulated from the context of large organisations and formation of balance policies to address the problem are often not appropriate for the SME context. Future theorisation of work-life integration in the SME context needs to be cognisant that the owner-manager often assumes multiple roles and tasks at the same time (Harris & Arendt, 1998) in an environment where the boundaries of work and life are blurred.

This paper is an effort to make just such a contribution and stimulate new thinking in the area. Our hope is that any future studies seeking to encapsulate the importance of personal motivations and possibly the stage of the owner-manager's personal and business lifecycle use qualitative methodologies to get close to the individuals in their comfort zones. In current regimes of reflexive modernization and flexible specialization, people need to compose their own biographies as worker, choosing between different lifestyles, subcultures, social ties and identities (Edwards, 1998). Certainly during our study we were privileged to hear of many joyous as well as difficult personal events and to learn about the resultant impact of these on the owner, their families and the business. Further research in this area also needs to be cognisant of variables including sector, owner choice, business constraints, culture, family size and personal lifecycle stage. Proposed solutions or answers to dilemmas of balance need to be relevant and realistic for SME owner-managers and the resources available to them. Given that there is no 'one size fits all' concerning ideals of work-life balance, personal choice needs to be highlighted as owner-managers will make decisions about their work and personal life based on their values, attitudes and beliefs.

## *Abstract*

*This paper considers the practice of using university undergraduate as proxies for small business owners in entrepreneurship research. A data set was gathered from a sample of university undergraduate students at a major business school as well as from a sample of actual small business owners “actual entrepreneurs”. The university undergraduate respondents were divided into those with high nascent entrepreneurial inclinations and those low in nascent entrepreneurial inclinations. A discriminate analysis between the three groups was then done and results were then and examined for similarities or differences with regards to life aspirations, life goals, and work goals of each group. Unlike the undergraduate respondents with low entrepreneurial potential, undergraduate respondents with high entrepreneurial potential were found to be very similar to actual entrepreneurs. Results of this research suggest that, when using students as proxies in the study of entrepreneurship, one needs to separate nascent from non-nascent students and use only those students who are high in nascent entrepreneurial inclinations.*

## *Entrepreneurship Research, Using Students as Proxies For Actual Entrepreneurs*

This paper considers the practice of using students as proxies for small business owners in entrepreneurial research. Past research has been done using undergraduate students (Segal, Borgia, Schoenfeld, 2002), always with the assumption that results are generalizable to the overall population of practicing entrepreneurs, but, to date, no study has examined the validity for this assumption. This study begins the process of correcting that. A population of 815 undergraduate students at a major university located in the Midwest were sampled using a questionnaire method while, in a similar time frame, a population of practicing entrepreneurs were given the same set of questions. The data was analyzed and results are provided in the discussion section of this paper.

A common theme found in entrepreneurship research is that entrepreneurship plays a critical role in the US economy. Of the 25.5 million businesses in the United States today, approximately 25.1 million or 98.5 % are small businesses. These small businesses are largely entrepreneurial and are responsible for 75.8% of our nation's new jobs. (Scarborough & Zimmer , 2003). Potential entrepreneurs appear to be critical to the notion of a resilient "self renewing" economic environment (Shapiro, 1982). Entrepreneurial growth is a critical part of our nation's economic health. Past research has also noted that Entrepreneurial potential seem to provide the best predictive power when attempting to predict the movement of the populace in the practice of entrepreneurship ( Kureger & Brazeal, 1994; Bagozzi & Yi, 1989). Research into entrepreneurial potential, therefore, serves us well, both in improving our predictive abilities and in providing a fertile ground from which the seeds of entrepreneurship can sprout.

Attracting the interest and time from existing entrepreneurs, however, is a difficult proposition. Acting entrepreneurs are pressed for time, resource short, and suspicious of anyone asking sensitive questions which might give away their competitive edge. A proxy, if found, without the above mentioned constraints, would be a welcome resource for entrepreneurship researchers.

In the past, undergraduate students, in university business schools, have been considered to be these proxies and, as such, representative of actual entrepreneurs. Students are not as time constrained as actual entrepreneurs. They are more accessible to researchers, assumed to be representative of the overall population, and are at the headwaters of their career path. The purpose of this paper is to explore the suitability of undergraduate students to serve as proxies for actual entrepreneurs in entrepreneurial research.

### **Ways of predicting Entrepreneurial Behavior**

Research exploring entrepreneurial behavior can be divided into four categories, how entrepreneurs act, what happens when they act, why they choose to act as entrepreneurs (Stevenson & Jarillo, 1990), and research into the identification of environmental and situational factors that predict entrepreneurial activity (Segal, Borgia, & Schoenfeld ).

Because of the above mentioned difficulties of studying actual entrepreneurs, environmental and situational factors, if effective, would be excellent avenues from which to study entrepreneurial behavior. Environmental and situational factors include job displacement, previous work experience, availability of resources, and governmental influences, all of which can be gleaned from data available outside the internal entrepreneurial environment. However, while each of these factors are considered to be important to the development and

encouragement of budding entrepreneurs, empirical studies of these contextual factors have found low explanatory power and predictive ability (Krueger, Reilly, & Carsrud, 2000).

Levesque, Shepherd, & Douglas, 2002 and Praag & Cramer, 2001, have proposed models using economic perspectives to predict self-employment. These economic models suggest that the decision to become self employed is based on maximizing the net usefulness, utility, or desirability of an entrepreneurial career. Shapero's model of the entrepreneurial event (SEE) assumes that inertia guides human behavior until something interrupts or displaces that inertia. All of the above methods remain wedded to various ad hoc profiles of personality and demographic characteristics. They do not depend on intimate contact with the actual entrepreneur and get around the difficulties in acquiring the more difficult internal information of the actual entrepreneur. However, they also appear to have minimal predictive ability (Krueger & Brazeal 1994).

Within the context of how and why entrepreneurs act, two theories, Ajzen's theory of planned behavior (TPB), and Social Cognitive Career Theory (SCCT) seem to hold some promise on the front of prediction of entrepreneurial behavior (Segal, Borgia, & Schoenfeld; Krueger & Brazeal ). Ajzen's theory of planned behavior suggests that three key attitudes predict entrepreneurial inclinations; (1) Attitude towards the act, (2) Social norms, and (3) Perceived behavioral control. Social Cognitive Career Theory suggests that Career interests, goals, and choices are related to self-efficacy beliefs and outcome expectations (Lent, Brown, & Hackett, 1994,1996). Segal, Borgia, and Schoenfeld make the suggestion, then, that peoples self efficacy beliefs and outcome expectations with regard to self-employment can predict their goals to become self employed.

Therefore, if entrepreneurship is viewed through the lens as simply one of many career choices, SCCT becomes a good benchmark from which to operate. It is a good place to hang ones theoretical hat as it is one of the most accepted and validated models discussed in the careers literature regarding the understanding of career interests and goals (Segal, Borgia, & Schonefeld; Gore & Leuwerke, 2000; Smith & Fouad, 1999; Swanson & Gore, 2000).

### **Social Cognitive Career Theory**

SCCT is anchored in social cognitive theory and highlights the importance of self-beliefs and self-thought in fostering an individual's motivation and subsequently guiding their behavior (Segal, Borgia, & Schoenfeld). Core variables of the SCCT model are (1) self efficacy-- which affects an individual's expectations for outcomes as well as their intentions toward performance, (2) outcome expectations---which affects their future performance or goals, and (3) goals--- for entrepreneurs towards self employment.

This model bases much of its predictive powers on Vroom's (1964) work in expectancy theory. Expectancy theory states that in order for an outcome to be achieved, three things must be in place; (1) a person must believe that he or she can do it (expectancy), (2) accomplishment of the task must be clearly connected to an outcome (outcome expectations), and (3) the outcome must be desired by the individual (valence). according to Vroom, an individual will choose among alternative behaviors by considering which behavior will lead to the most desirable outcome. SCCT suggests that these outcome expectations are important determinants of career interests (Segal, Borgia, & Schoenfeld). Bandura (1986) noted that a person's behavior results from the interaction of that person and their environment but, as noted above, issues of the

environment contain low explanatory power and predictive ability when used alone (Krueger, Reilly, & Carsrud, 2000).

Therefore the researcher finds himself dealing with other methods of studying entrepreneurial behavior, expressed in general terms of how and why entrepreneurs act and what happens when they act. Past studies have shown these areas to be more fruitful in their predictive and exploratory powers to explain entrepreneurial behavior. However, the thorny issue of gaining access to actual entrepreneurs remains. Since the more easily gathered data (economic and demographic) appears to be ineffective, the obvious alternative is to use some form of a more accessible proxy for the ever busy and difficult to reach actual entrepreneur. This effort to locate proxies high in entrepreneurial potential is seen as a major stumbling block to a precise description of the entrepreneurial effort (Reynolds, 1995). One possible source for these nascent entrepreneurs is located in universities. However, results of past entrepreneurial research using students have been mixed at best.

### **Focus of This Paper**

This paper looks, in particular, at the issue of using students as proxies for actual entrepreneurs in entrepreneurial research. We suggest that an acceptable proxy will be one with high potential to become an actual entrepreneur.

Because recent research suggests promise for Social Cognitive Career Theory this paper concentrates on those traits and issues that best fit into the Social Cognitive Career Theory realm to provide discrimination between students exhibiting nascent entrepreneurial tendencies and students low in these nascent entrepreneurial tendencies (Segal, Borgia, & Schonefeld; Gore &

Leuwerke, 2000; Smith & Fouad, 1999; Swanson & Gore, 2000). In particular, we look at measures of life aspirations along with work and life goals within a sample of junior and senior level undergraduate students at a major Midwest university. We also look at the same measures within a sample of actual entrepreneurs who agreed to participate in our research.

Students high in nascent entrepreneurial inclinations, for the purposes of this research, are defined as those individuals who exhibit high potential to become actual entrepreneurs (Reynolds, 1995; Palit & Reynolds, 1993; Reynolds & White, 1993). Undergraduate respondents were divided into two categories. We develop a nascent entrepreneurship index and make a distinction between those who score high on this index and those who scored low. Our expectations were that students exhibiting high levels of nascent entrepreneurship, as evidenced by their score on the nascent entrepreneurship index will respond similarly to actual entrepreneurs in the administration of the questionnaire.

Our attempt is to validate the link between those undergraduate students with a high level of nascent entrepreneurial inclinations and actual entrepreneurs and as such validate their use as proxy's for the much more difficult to obtain data from actual entrepreneurs. Furthermore, we look at the lack of correlation between the answers given by those students who are low in nascent entrepreneurial inclinations and actual entrepreneurs and suggest that, in order to improve the reliability of using university students as proxies for actual entrepreneurs, one needs to separate out those students who exhibit low nascent entrepreneurial inclinations.

## **Methodology**

The study was done through the use of a nearly identical questionnaire administered to a group of approximately 500 university students as well as 286 actual entrepreneurs. The

questionnaire items are grouped into two main categories of work goals (Table 1) and life aspirations (Table 2). These items were derived from those used in current entrepreneurial research. The respondents were asked to rate the importance of (1=not at all important, 7=extremely important) seventeen job characteristics (work goals) in their ideal jobs. They were also asked to divide one hundred points among ten life goals/aspirations to indicate the relative importance of each in their lives.

**Table 1; Work Goals**

|  |
|--|
| <p>To be able to use my skills and talents to the maximum</p> <p>To be able to achieve something that I personally value</p> <p>To work with others as members of a group</p> <p>To have the freedom/opportunity to make my own decisions</p> <p>To have job security</p> <p>To have the opportunity to learn new things</p> <p>To receive attractive pay and benefits</p> <p>To perform challenging and exciting work</p> <p>To be able to extend my range of abilities</p> <p>To have opportunity for advancement/promotions</p> <p>To be friends with, and be liked by my co-workers</p> <p>To have the authority to influence others</p> <p>To always know specifically and exactly what I am expected to do</p> <p>To have fixed working hours</p> <p>To be able to set my own working hours</p> <p>To have control over the pace of my work</p> <p>To be ultimately involved in the entire operation (i.e. the whole enterprise)</p> |
|--|

**Table 2; Life Goals and Aspirations**

|   |
|---|
| <p>Accumulate wealth</p> <p>Control my own future</p> <p>Be my own boss</p> <p>Have free time for family, hobbies, leisure, and other interests</p> <p>Live an adventurous and exciting life</p> <p>Be recognized by family/friends for my accomplishments</p> <p>Become an influential person</p> <p>Have a steady paycheck (i.e. job and income I can count on)</p> <p>Have financial security</p> <p>Have peace of mind (i.e. peaceful and stress-free life)</p> |
|---|

The sample was already naturally divided into two groups, that of students and actual practicing entrepreneurs. We further divided the student group into those students with low nascent entrepreneurial qualities and those with high nascent entrepreneurial qualities. This was done through deriving an average score for each student based on responses to four questions (Table 3). Students responded to the questions in the form of a likert scale of 1-7. Students who scored an average response of three or less to the questions in Table 3 were classified as having low nascent entrepreneurial qualities. Students who scored an average response of five or higher to the questions in Table 3 were classified as having high nascent entrepreneurial potential. Students who scored an average of 3 were discarded as being too ambiguous to classify into either category for the purposes of this research.

**Table 3: Nascent/Non-nascent questions**

|   |
|---|
| My ultimate goal is to be self employed               |
| My goal is to start my own business                   |
| Having a job is more appealing than owning a business |
| I intend to strive for an idea to own my own business |

This process allowed three distinct groups to emerge. These were actual entrepreneurs, students exhibiting high nascent entrepreneurial potential (referred to as nascent), and students exhibiting low nascent entrepreneurial potential (referred to as non-nascent). The entrepreneurially nascent students numbered 156. The entrepreneurially non-nascent students numbered 183. 161 students delivered scores of 3 and were considered too close to differentiate. Total students participating in the research were 500. These groups were then subjected to three combinations of a two way discriminate analysis using work goals and life aspirations as independent/predictive variables. The first analysis looks at the non-nascent student group compared to nascent student group. The second analysis looks at the non-nascent student group

compared to actual entrepreneurs. The third and final analysis looks at the nascent student group compared to actual entrepreneurs.

## **Results**

Results from a discriminate analysis are found in Table 4: Analysis 1. Responses of students categorized as non-nascent are compared to those categorized as nascent. In this analysis our results showed that work goals and life aspirations correctly classified 75.5% of the two cross validated groups of students (nascent and non-nascent) in the analysis. This indicates a strong difference between these two types of students. This supports our assertion that there is a significant difference in work goals and life aspirations between students exhibiting strong nascent entrepreneurial qualities and those exhibiting weak or non-nascent entrepreneurial qualities. Perhaps even more relevant is that only 21% of non-nascent students were incorrectly classified as actual entrepreneurs, which is exactly the same as the percent of non-nascent students who were incorrectly assigned to the nascent group.

Analysis two moves the discussion forward by comparing the non-nascent student group to actual entrepreneurs. Here the results are even stronger with 82.7% of cross validated grouped cases correctly classified in the analysis (Table 5). This indicates that there is a difference between the non-nascent group and the group of actual entrepreneurs and suggests that the non-nascent group of students may not be representative of or serve as proxies for the actual entrepreneur in entrepreneurial research.

Analysis three moves the discussion in a final step by comparing the nascent student group to actual entrepreneurs. Here the results are weaker with only 70.1% of cross-validated

grouped cases correctly classified (Table 6). However, the separation becomes even more indistinct when it is noted that, of the nascent student group, the discriminate analysis was only able to correctly identify them 48.1% of the time. Furthermore, the discriminating variables are not only different from those that separate non-nascent from the other two groups but also different from those which are supported by the literature as being a part of the entrepreneurial profile. This lack of discriminatory ability using questions previously identified as being a part of the entrepreneurial profile. This highlights the similarity of the nascent and actual groups and their dissimilarity with the non-nascent group thereby suggesting that nascent entrepreneurial students are very much like actual entrepreneurs and can serve as inexpensive and accessible proxies in their absence for both predictions of entrepreneurial activity and other forms of entrepreneurial research.

Table 7 shows the most discriminating questions found in the analysis. Reported are those questions with a factor loading of .2 or more. 18 questions were found to have a factor loading of .2 or greater in at least one of the three analyses. In fact, characteristics that most significantly discriminate between the actual/non-nascent and between the nascent/non-nascent subjects are virtually the same. Again highlighting the fact that actual and nascent entrepreneurs are very similar to each other and very dissimilar to non-nascent subjects. Twelve questions were found to have a factor loading in either or both of analyses one and two. In fact, both groups attach significantly more levels of importance to eight questions in particular. These questions have a factor loading of at least .25 in both analyses one and two (Table 7), and include; Be my own boss(high inclination), number one in both analyses; Be able to set my own working hours(high inclination), number two in both analyses; Have freedom to make my own decisions(high inclination); Be intimately involved in entire operation(high inclination); Had a

role model owning business(high inclination); Have control over pace of work(high inclination); Have a job and income I can count on(low inclination); Have fixed working hours(low inclination); Father occupation (high inclination); and to have job security (low inclination).

## **Implications**

As previously mentioned, acting entrepreneurs are pressed for time, resource short, and suspicious of anyone asking sensitive questions which might give away their competitive edge. Our results indicate that students can serve as proxies for acting entrepreneurs as long as we separate those with high nascent entrepreneurial inclinations from those without such inclinations (referred to here as non-nascent). This can be done through the use of student responses to Questions concerning their entrepreneurial inclinations (Table 3). As noted from discriminate analysis three, students registering high in the nascent entrepreneurial index are found to be quite similar to actual entrepreneurs with the analysis having difficulty discriminating between the two groups. On the other hand, students in the nascent group are found to be quite dissimilar to the non-nascent student group (Table 7: Analysis one). Students in the non-nascent group are found to be quite dissimilar to actual entrepreneurs as well (Table 7: Analysis two). Therefore, when using students as proxies for actual entrepreneurs, researchers would do well to distinguish between those who score high in nascent entrepreneurial inclinations and those who do not.

**RISK MANAGEMENT PRACTICES IN GERMAN SMES:  
AN EMPIRICAL INVESTIGATION**

**ABSTRACT**

This paper reports current risk management practices in German small to medium-sized enterprises (so-called German “Mittelstand”). In particular, it studies possible relationships between risk management and business planning activities. Additionally, it determines to what extent the Balanced Scorecard is used, for the general purpose of performance measurement and especially for the purpose of risk management. The inquiry was carried out by means of a postal questionnaire. The results show that in German SMEs the handling of risks is strongly concentrated on owner-managers. Risk management is carried out in a rather rudimentary way. Only few SMEs have established a comprehensive business planning system, and the link between their risk management and their business planning is in most SMEs not well developed. But a sound risk management requires an elaborate business planning, together with a direct

mapping of risk figures into the planning system. In general, the Balanced Scorecard was met open-minded, but its use for risk management is mentioned by only a few enterprises. This investigation is a first step of a larger empirical approach to risk management practices in German SMEs.

## **INTRODUCTION**

Concerning risk management practices in Germany, there have been conducted many studies that deal with large enterprises. SMEs, however, have been neglected in risk management considerations. This empirical investigation aims at filling this gap. It is a first step of a larger project to study risk management practices in German SMEs.

The paper is structured as follows: This introduction section contains some preparatory remarks on enterprise size classes, the definition of SMEs and the basics of risk management. Then a risk management framework is outlined that is fundamental for the rest of this paper: it connects risk management with business planning and the Balanced Scorecard (BSC). The literature review following focuses on just these topics, together with some remarks on SMEs' behaviour. After that the research method of questionnaire survey is described by which this investigation has been carried out. Next, the questionnaire results are presented. The paper concludes with a discussion about the research findings, their practical implications and the need for further investigation.

SMEs form the backbone of the West European economy. About 90 per cent of them are enterprises with less than 10 employees (so-called micro firms). In Germany there are about 3

million SMEs with a total of about 20 million employees (Bretz, 2003; Statistisches Bundesamt, 2004).

In quantitative terms, the category of SMEs is made up of enterprises satisfying at least the following conditions: fewer than 250 employees, annual turnover not exceeding 50 million Euro and/or annual balance sheet total (total assets) not exceeding 43 million Euro. Moreover, an additional independence criterion must be fulfilled: a maximum of 25 per cent of its capital may be held by other enterprises that do not satisfy the above employee and turnover/balance sheet total conditions (The Commission of the European Communities, 2003).

Size classes for enterprises have been defined because the range of firms does not show a homogenous structure, for example with respect to the knowledge of business methods or their decision-making.

Referring solely to the number of employees, the following definition is shared by many researchers (and also by EUROSTAT, the statistical office of the European Union; see The Commission of the European Communities, 2003):

- micro firm:                up to 9 employees
- smallfirm:                10 to 49 employees
- medium-sized firm:    50 to 249 employees
- large firm:                250 and more employees

Risk and uncertainty – the basic terms of risk management – characterize situations where the actual outcome for a particular event or activity is likely to deviate from the estimate or forecast value. Risk can travel in two directions: the outcome may be better or worse than originally

expected. These are known as upside and downside risks. The distinction is usually that risk is taken to have quantifiable attributes, whereas uncertainty does not. Uncertainty, on the other hand, is used to describe situations where it is not possible to attach a probability to the likelihood of occurrence of an event (Raftery, 1994).

Risk management is a continuously monitored integrated formal process for defining objectives, identifying sources of uncertainties, analyzing these uncertainties and formulating managerial responses, to produce an acceptable balance between risk and opportunities. As usual, the steps of the risk management process are called identification, evaluation and monitoring. Enterprise risk management must be a top-down process. Management has the overall view and can define the thresholds of risk figures. Conversely, information must be fed back to the top from those closest to the sources of risk (Dickinson, 2001).

In 1998 the German Control and Transparency Act (KonTraG) had come into force, which in Germany led to new discussions on the problems of risk management. This law distinctly demands establishing a so-called “early warning system” by which enterprises can perceive in time those developments that endanger their existence. The act directly addresses only public limited companies. Although it has a spillover effect also on SMEs, recent empirical studies on German risk management practices concentrate merely on large enterprises (see, for example, Fischer, 1999; KPMG, 2000; PriceWaterhouseCoopers, 2000; Reichmann and Diederichs, 2003; Federation of European Risk Management Associations et al., 2004).

The general approach of this paper aims at establishing a link between risk management and business planning, with the Balanced Scorecard supporting risk identification. The following

figure shows the constituents of this risk management framework, together with their relation to the corresponding classical steps of the risk management process.

---

Figure 1 Risk management framework

---

Some remarks on the connections (1) to (3) in Figure 1 follow:

**(1) Identification of risks and the corresponding master budget entries by the Balanced Scorecard**

Risks are identified with the BSC. The ratios of all perspectives of a BSC can be associated with certain entries of the master budget. For ratios of the financial perspective this is obvious.

Similarly, the ratios of the other perspectives (e.g. customer complaints rate) can be related in a more or less complicated way to corresponding master budget entries (e.g. repair and maintenance expenses). Thus developing the control measures of a BSC allows it to identify those corresponding entries of the master budget that are of risky nature. The BSC has proved (Chow et al., 1997; Oepping and Siemes, 2003) to be a popular instrument for a comprehensive enterprise performance measurement. Hence this established instrument could be easily used for the purpose of risk management in SMEs.

**(2) Evaluation of risks using the link between risk management and business planning**

Risks are identified according to the entries of the master budget. Threshold values for the identified risk entries are fixed without referring to mathematical or statistical procedures.

Measures are planned that should be taken if risk figures violate the corresponding thresholds,

and the development of these thresholds is included in the reporting. The short personnel and financial resources of SMEs do not permit a separate risk management with risk management experts. Thus a link between risk management and business planning ensures a systematic and complete risk assessment within a familiar frame.

### **(3) Monitoring the effects of risks on the target figures for profit and liquidity**

The usual input values of the master budget lead to the planned values of the target figures for profit and liquidity. Analogously, one can estimate the effects of risks on profit and liquidity if one replaces the usual input values by threshold values of risk entries. This assumes a certain embedding of the risk figures into the business planning system. The risk awareness of the staff is developed if they are confronted with this “playful” way of demonstrating the effect of risks. The range defined by the variation of the target figures profit and liquidity when performing risk considerations is included in the form of ratios in the BSC.

The risk management framework, as presented in Figure 1, gives rise to the following research questions:

- Under what conditions is risk management carried out in the main industries of German SMEs?
- In which way has their risk management process been linked to the business planning?
- To what extent do German SMEs use the Balanced Scorecard? In particular: Do they use it for the early warning of risks?
- Do their organization and techniques of risk management depend on enterprise size classes?

## **LITERATURE REVIEW**

The literature review assembles sources that cover the main issues of the risk management approach of this paper: general risk management, followed by business planning and the Balanced Scorecard with the focus on their respective support of risk management purposes. Before dealing with these areas, some studies about SME behaviour are summarized.

Up to now there are no empirical investigations on risk management practices in German SMEs. Hence the literature has been reviewed critically to detect which risk management techniques proposed for foreign SMEs and even for larger enterprises in general could also be suitable for German SMEs.

### **SME Behaviour**

McKiernan and Morris (1994) point out the following qualitative characteristics of SMEs: central role of the owner with multiplicity of duties and close identity with employees, combination of ownership and control and inherent flexibility and mobility.

SMEs mainly operate on the domestic market, partly because of short resources and the fear of unknown foreign business practices. In general, SME owners have no broad knowledge of business administration (Dutta and Evrard, 1999).

According to Lyles et al. (1993), SMEs show little separation between the entrepreneur's strategic thinking and decision-making and the enterprise's formal planning system.

Brouthers et al. (1998) stated that decision processes in SMEs occur more intuitively and that for analyzing strategic alternatives quantitative methods are used rather seldom. With increasing size enterprises act “more rational” with respect to planning and decision-making.

Enterprises in their start-up phase often underestimate risks or even ignore them completely (Smith, 1998). Start-up SMEs usually face a high degree of uncertainty and the necessity to make quick decisions (Frese et al., 2000).

Empirical studies show that the attitude of SMEs towards risks and their risk assessment differs significantly from that of large enterprises. Since risk considerations in SMEs take place in a more holistic way, elaborate mathematical methods for risk evaluation should be avoided.

Risk management practices in small firms relate to the beliefs and attitudes of founding entrepreneurs. SMEs do not tend to use special techniques to optimize single risks. They make decisions in terms of their business as an entity rather than in terms of managing specific risks. Despite having performed some form of risk identification and evaluation, small business owners may simply ignore a particular risk (Sparrow, 1999; Sparrow and Bentley, 2000).

## **Risk Management**

In large German enterprises, primarily the board of directors and secondly a special risk manager (probably leading a separate risk management function) are reported to be responsible for risk management. In more than half of the large enterprises internal audit is responsible for supervising and reviewing risk management. Concerning risk identification and evaluation, large enterprises primarily name designated employees of business units; then management and risk managers follow (PwC, 2000).

According to Reichmann and Diederichs (2003) and KPMG (2000), large enterprises use to review their risks annually or quarterly. The risk monitoring horizon in large enterprises is about 2 to 5 years. KPMG (2000) found out that 77 per cent of all large enterprises have established a direct integration of risk management into their business planning. The majority of large enterprises come to investments for their risk management system of 50.000 Euro to 250.000 Euro (Fischer; 1999). A recent study of the Federation of European Risk Management Associations et al. (2004) reports that in Germany the main activities of the questioned large enterprises consist of implementing and embedding their risk management process.

A fundamental study of Turpin (2002) examines the state of risk management in SMEs of various European countries, including Germany. This is the only empirical investigation on current risk management practices in SMEs. Unfortunately, its focus is on the specific characteristics of insurance. Moreover, the size classes of micro and small firms are neglected. Turpin also states that 4 out of 10 enterprises have no official risk strategy, which is due to problems of communication and of delegating risk management competencies to employees. In European SMEs the five most frequently mentioned risk are: increasing competition, loss of employees to competitors, changing customer demands, wrong strategies due to lack of market data and personnel absence rate.

According to Turpin (2002) in Germany 60 per cent of the surveyed enterprises review their risks monthly, 24 per cent quarterly. Then 9 per cent with reviewing if required and 4 per cent with reviewing every 6 months follow. The large proportion of monthly reviewing may be a consequence of the enterprise size; the study covers SMEs up to 500 employees, which is far beyond the classical definition. Summarizing, only few German enterprises could answer

detailed questions concerning the structure of their risk management and their actual risk position.

Eck et al. (2000) is the first study that concretely implements a direct connection between risk management and business planning, a central element of the framework of Figure 1. The authors present a simulation model for financial planning, that had been extended to include risk management aspects. They have carried out a case study with a construction enterprise where their system had been implemented. The cited financial planning model uses as a pre-system an integrated planning system in the form of a master budget. Omitting the technical details, Eck et al. indicate how risk considerations can be handled by this simulation model. There is no precise description how the entered risk data are processed within the planning model.

The approach of Eck et al. assumes that an enterprise has already established a comprehensive business planning system. Regarding SMEs, it must be investigated whether this assumption is justified. The simulation system may be easy to apply, but establishing and customizing it seems to be a complicated process. The empirical testing of the system has taken place within only one firm. Finally, the model of Eck et al. does not consider qualitative risks.

SMEs identify two barriers to risk assessment: time pressure and access to suitable guidance.

The time commitment associated with the various aspects of risk assessment is mentioned by a majority as being problematic. Given access to appropriate guidance and information, SMEs can implement risk assessment effectively (O'Hara et al., 2005).

## **Business Planning**

Planning in small-scale enterprises is related to success only in cultures that value uncertainty avoidance. Germany is such a country with high uncertainty avoidance. In Germany, the quality of planning is positively related to success. Business planning is considered to be an important instrument to achieve success. SMEs judge business planning as a useful instrument to deal with uncertainties (Rauch et al., 2000).

In general, Weber (2000) claims that the literature shows that business planning in German SMEs is not carried out in great detail. Planning has a rather short time horizon. Comparing planned and actual values and analyzing deviations takes place rather seldom. Often business plans are not written but only fixed in the mind of the owner-manager. Risk aspects do not occur in business planning.

In order to expand, SMEs heavily rely on external funding sources for their support, and these sources usually impose planning requirements on the firm (Matthews and Scott, 1995).

Peel and Bridge (1998) stated that many SMEs use strategic thinking and planning techniques only in critical circumstances. The more turbulent the environment is, the more strategic planning is a success factor. Those enterprises that used strategic planning had a better financial performance.

Buchner and Weigand (2002) propose that business planning systems can support the identification of risks effectively, the systems' forecast options being particularly helpful.

## **Balanced Scorecard**

Nørreklit (2000, 2003) critically analyzes the key assumptions and relationships of the BSC, as introduced by Kaplan and Norton (1996). The author thinks the BSC to be a good alternative to the classical financial control instruments. She emphasizes two essential weaknesses where the BSC needs improving to become an optimal performance measurement system: one weakness is that there are no time perspective considerations.

On the other hand, business planning admits strategic (i.e. long-term) and operational (short-term) considerations. Thus, in the opinion of the author of this paper, establishing a close connection between the BSC and the business planning system can overcome the cited weakness with respect to the time dimension.

According to the experiences of Chow et al. (1997), the BSC is, until now, used mainly in large companies. External and internal scanning is stated to be an important task to deliver information for the BSC. Using the BSC for risk management is only mentioned implicitly. A detailed description of a link between risk management and the BSC is lacking.

Geiger and Hermann (2003) established a BSC in some German SMEs. They recommend to chose distinctly less than 20 strategic objectives since – compared to large enterprises – in SMEs the company organization is less complex. Having fewer strategic objectives means at the same time concentrating on essential contexts and easier manageable actions. In their day-to-day operations, SME treat strategic considerations rather poorly. The BSC may contribute to the aim that strategy revision and strategy translation become a natural and permanent process.

Rossmann and Kabela (2004) introduced a BSC in a small enterprise and report the following improvements: operationalization and effectiveness when formulating strategic objectives, concentration on fundamental business processes, reduction of reporting to essential target figures and improvement of internal communication. The authors recommend to develop the BSC by workshops of management and designated employees. In this way a common understanding of strategic objectives and strategies can be achieved.

## **RESEARCH METHOD**

To investigate the current risk management practices of German SMEs, as a first step a questionnaire survey has been carried out. The use of a questionnaire was preferred to rapidly obtain data at relatively low costs. The questionnaire was designed along the lines of the general risk management framework of Figure 1.

At the beginning of developing the questionnaire, discussions with experts had been held, such as university lecturers and risk management specialists of two international auditing and consulting firms (both firms also work for medium-sized enterprises). Furthermore, 10 interviews with German SMEs had been performed.

Subsequently a test pilot study was carried out in the form of an online questionnaire. About 170 German SMEs have been contacted by e-mail requesting them to fill it in. This led to the return of 28 usable questionnaires. The results of the pilot study were not included in the evaluation of the main mailing action.

To gain an overview of the number of SMEs in different industries, the German Value Added Tax statistics (VAT; Statistisches Bundesamt, 2004) have been referred to. These statistics are

divided into industries in accordance with the standard industrial classification, namely the Nomenclature Activity Classification Europe (NACE code). Regarding all enterprises with annual turnover up to 50 million Euro (these statistics do not allow another classification using the number of employees) shows that the industries of construction, engineering, information technology, auditing/consulting/training and service/logistics together make up about 60 per cent out of a total of about 3 million enterprises. The questionnaire of this study addresses German SMEs of just these five industries.

As a source to draw the questionnaire sample from, the Hoppenstedt (2000) SME database was used. This database is annually updated and contains information about c. 200,000 German SMEs; it is the largest SME database in Germany, and it is also classified according to the NACE code. By the technique of cluster sampling, all enterprises with a number of employees up to 250 and an annual turnover up to 50 million Euro within the above five industries were selected. This led to a mailing list with a total of 1,292 SMEs.

To improve the response rate, a freepost envelope and a coupon to order the results of the study were attached to the mail. It was decided not to carry out a follow-up for the mailing action. Newby et al. (2003) and Dennis (2003) found out that, in the case of SMEs, a follow-up does not lead to an improvement of the response rate. Crucial for a good response rate is that a questionnaire deals with issues that are interesting for SMEs.

A total of 304 questionnaires had been returned making up 24 per cent of those sent out. The number of usable questionnaires returned by enterprises having at most 250 employees was 240, which is a response rate of 19 per cent. This response rate is in line with other SME studies (Clink, 2001).

35 questionnaires were returned with some remarks about why they had not been filled in. Most frequently it was stated that the enterprise had already been closed or was insolvent. Less frequently “Filling in not wanted.” was returned. Another reason for not filling in was that the respondent may not meet the research requirements: “No SME, but part of a group”. This is due to the effect that, at the time of survey, the Hoppenstedt database was slightly out of date.

The questionnaire format is highly structured. Close-ended questions facilitate the evaluation. A multiple choice approach helps the respondents to give the applicable answers. There are two fundamental types of questions: those that demand exactly one outcome to be selected and those that allow multiple selection.

Evaluating the questionnaire results depends on the type of scale by which they can be appropriately encoded. On the one hand, there are nominal scales (e.g. industries). On the other hand, there are metric scales (e.g. number of employees). As usual, outcomes measured by metric scales are grouped into classes (in the case of the number of employees this is done in accordance with the classical enterprise size classes). And then there are many questions where the possible outcomes have an intrinsic ranking, like good / intermediate / bad (see, for example, the link of risk management to business planning in Table 7, where good = direct integration / intermediate = no direct integration / bad = no link at all). Encoding the outcomes of such questions by integer numbers corresponding to their “natural” ranking (for example, 2 / 1 / 0) leads to ranking scales, that can be treated as a special case of metric scales. Finally, dichotomous (“Yes / No”) questions are encoded in the usual way by the numbers “1 / 0”.

The outcomes of single questionnaire results are treated by means of descriptive statistics. When discussing whether certain questionnaire outcomes depend significantly on enterprise size,

Pearson's correlation coefficient  $r$  is computed (which, at least, needs ranking scales). Here, when the significance of these correlation results is estimated, inferential statistics comes into play. Deriving from  $r$  (by means of Student's  $t$ -distribution) a corresponding  $p$ -value, the significance can easily be obtained (see Tables 9 and 10).

## RESULTS

For the sake of clarity, the following frequency tables of the questionnaire results contain only the summarized proportions of all SME responses. Interesting results referring to details of the size classes of micro firms, small firms and medium-sized firms are mentioned additionally within the comments.

### Basic Enterprise Data

The main industries of German SMEs addressed by the questionnaire have the following distribution:

---

Table 1 Response by industries

---

The dominating industries are engineering and construction, each with about 1/3 of the respondents. The other three industries each make up about 10 per cent.

---

Table 2 Response by enterprise size

---

With more than 80 per cent the size class of medium-sized firms is clearly dominating, while micro firms are underrepresented. The original employee data have an average of 85.7 employees per enterprise.

### **Business Planning**

Only one third use a master budget (integrated system), which shows that business planning in SMEs is often carried out in a rather rudimentary form. In other words: their business planning does not correspond to the classical model. The budgeted profit statement is used most frequently. A cash budget is applied by about 1/3. This is questionable because many SMEs have problems with their liquidity and with managing their finances and are in danger of becoming insolvent. Balance sheet planning has no meaning for SMEs. It is generally accepted that business planning is basic for a risk management system. Hence business planning must be improved.

It is interesting that in the size class of micro firms only 12.5 per cent (1 out of 8) use a master budget. 37.5 per cent do not even make any statement about planning, which means there might be no formal planning system at all.

---

Table 3 Business planning systems

---

Concerning the time aspect of business planning, a short planning horizon dominates. On the one hand, SMEs work in small market segment or niches where large firms do not want to offer

products. Therefore SMEs must continuously watch market changes and cannot plan for the long term. On the other hand, SMEs must adapt to the customer needs more rapidly.

In the class of micro firms the planning horizon of 50.0 per cent is one year. It is remarkable that within this class often no statement was made (16.7 per cent). A size effect is recognizable: In the classes of medium-sized firms a planning horizon of 4-5 years most frequently occurs.

### **Risk Management**

Most of the respondents report the board of directors as responsible for organizing risk management. Then the controlling department and the chief financial officer follow. Only very few have a special risk manager, i.e. risk managers have no practical meaning for SMEs.

Because of the strong link between the owner-managers' well-being and that of their enterprise, in most cases in SMEs the management is responsible for risk management. The owner-manager's own best interests are the handling of risks. The extent and the quality of risk management in SMEs widely depend on how much time the owner-manager invests in the development and implementation of an official risk strategy and how it is communicated to the respective employees.

---

Table 4 Responsibilities for risk management

---

Concerning the supervision and review of the risk management system, within all SME size classes, the board of directors also dominates, confirming that risk management in SMEs is orientated towards the owner-manager. Then controlling department follows, showing a distinct

domination within the class of medium-sized firms. The internal audit has no meaning for supervising and reviewing SMEs risk management.

The documentation of the risk management process is mostly contained in the general procedural manual. Other statements such as documentation within the quality manual or the minutes of board meetings nearly make up the same proportion of about a quarter. A special risk management manual or documentation has not an issue for SMEs. It is interesting that 60 respondents (out of 227) made no statement at all, which again makes up about a quarter.

---

Table 5 Risk categories

---

The most important risk categories are market risks, strategic risks and business process risks. Financial risks – presumably from liabilities and credit worthiness – follow. Financial risks can extend to many other types of risk: risks from interest rates, exchange rate movements and the value of investments, for example. Acting on the domestic market and working with fixed interest rates, all these risks are of no importance for German SMEs (see Dutta and Evrard, 1999; Müller et al., 2004). A clear size effect can be recognized: with increasing size the enterprises deal with more risk categories.

---

Table 6 Risk identification and evaluation

---

Risk identification and risk evaluation is concentrated on management alone and on management together with departments. The controlling department follows, the medium-sized firms strongly

dominating within the sizes classes. In micro and small firms the identification and evaluation of risks is clearly concentrated on management, being in accordance with the results concerning risk management responsibilities (see Table 4).

Most enterprises review their risks quarterly (in contrast to the domination of monthly reviewing, as reported by Turpin, 2002). The other frequencies of risk review (every year, every 6 months, every month, other period) are approximately uniformly distributed. In the class of micro firms, 25.0 per cent of the questioned enterprises review risks every 6 months, and 62.5 per cent of them have filled in “other period” (such as: current, as required, depending on the risk).

The time horizon of risk reviewing concentrates on a short-term period of 1 to 2 years (more than 2/3). It is interesting that 13.7 per cent have chosen the option “Open”. Fixing no period for risk review indicates that risk management is not carried out very systematically. Rather short periods correspond to the results considering long-term business plans (see Table 3). Short-term review cannot perceive strategic risks in time. Since 2/3 assert to deal with strategic risks, this cannot be carried out in a very systematic way. In the class of micro firms the time horizon for risk review is extremely short-term (1 year). Here even 37.5 per cent state their risk review to be open.

Management is informed about risk within the general reporting system (72.6 per cent). A separate risk reporting has no importance for SMEs (8.7 per cent).

About two third of all SMEs use standard business software for their risk management (such as MS Excel, MS Access). Standard business administration software comes second, and in-house software comes third. Special risk management software is used by only 3.0 per cent. The low degree of automation and interlinking of risk management solutions by standard business

software leaves risk communication to the initiative of the employees. There are problems to coordinate information and thus to give management an overview of the current risk position. Because of high cost and the request with respect to technical know-how risk management software for SMEs is out of the question.

Two third of the enterprises have made no investment to establish or to improve their risk management. This clearly shows that SMEs do not want to spend additional money for establishing or developing a risk management system. Hence a risk management model being acceptable for SMEs must get along without additional investment cost and be linked into the existing information technology.

---

Table 7 Link of risk management to business planning

---

Only 1/3 of the surveyed cases showed a direct link between risk management and business planning. This means, that 2/3 of the SMEs are not able to determine the effect of risks on the target figures for profit and liquidity. The results suggest that the questioned enterprises perform risk management in a rather simple and not very comprehensive way. Combining risk management and business planning is clearly favoured but the decisive step to a direct integration of risk into the business planning still has to be done. Since SMEs in their founding phase show an increased danger of becoming insolvent (Bretz, 2003; Günterberg and Kayser, 2004), such a step would be an important measure of preventing business failure. In the class of micro firms, a direct link of risk management and business planning is developed in the weakest way, and in the class of micro firms it is stated very frequently that there is no link of risk

management and business planning at all (37.5 per cent). Both results may be up to the business planning being not very detailed (see Table 3).

### **Balanced Scorecard**

The use of the Balanced Scorecard is surveyed in two directions: firstly, its general use as a comprehensive measurement system, and secondly, its specific use for risk management purposes. 28.1 per cent of the enterprises already use the BSC or plan to use it. Hence SMEs show great interest in the BSC, in contrast to their behaviour with respect to other management concepts being proposed by business administration literature. It is pointed out that about half of those 25 enterprises already using the BSC employ it for risk management purposes. Here a questionnaire survey cannot determine the details how SMEs use the BSC for their risk management. Considerably few micro and small firms use the BSC.

---

Table 8 Use of Balanced Scorecard

---

### **Correlations**

To detect significant size effects, some important questionnaire results have been correlated with the enterprise size, as measured solely by the number of employees (see Introduction). To compute Pearson's correlation coefficient, the size classes of micro firms, small firms and medium-sized firms have been used, where the latter has been divided into further subclasses.

A correlation is called to be of type 1 if it relates enterprise size with the outcomes of a question that demands unique selection from the options it offers.

---

Table 9 Some correlation coefficients of type 1

---

Risk management: Risk review frequency, risk review time horizon and the integration of risks into the business planning all do not depend significantly on enterprise size. In contrast to what one would expect, with increasing enterprise size risks are not reviewed more frequently, the time horizon of risk reviewing is not longer, and there is no tendency that risks are linked to the business planning or even directly integrated into it. The reason is that – independent of the size of SMEs – there is no risk management framework being suitable for them.

Balanced Scorecard: With increasing size enterprises significantly tend to use the BSC or at least plan to use it. On the other hand, the use of the BSC for risk management purposes does not depend on enterprise size (it is emphasized that this second result is based on a relatively small total number).

A question allowing multiple selection from the options it offers can be viewed as a set of independent “Yes / No” options. A correlation is called to be of type 2 if it relates enterprise size with the outcome of one single (dichotomous) option of a question that allows multiple selection.

---

Table 10 Some correlation coefficients of type 2

---

Responsible for risk management: The influence of the Board of Directors decreases with increasing company size. A reason is that larger enterprises may have more competent employees to take on these tasks and that from a certain size on risk management becomes too

complex to be performed by the Board alone. In addition, with increasing size a designated risk manager and the controlling department with high significance both become more important for risk management. Finally, with increasing size companies report other persons as responsible for risk management; internally they name quality management representatives, and externally they are supported by chartered accountants or management consultants.

Risk categories: Among all risk categories considered, group company risks are the only ones that significantly depend on enterprise size: With increasing size, these risks are considered by more enterprises. Larger enterprises are more likely to be involved in investments in a company which needs an appropriate controlling of investments and risk assessment.

Risk identification and risk evaluation: The influence of management decreases with increasing company size (high significance). Conversely, with increasing size the influence of the controlling department increases, and other ways of risk identification and evaluation are considered more frequently (with the same specifications for internal and external support as in the section “Responsible for risk management”). Again this shows that larger enterprises tend to take advantage of external advice.

## **CONCLUSION**

The questionnaire results have shown that risk management in German SMEs is clearly orientated towards the owner-manager. It is carried out in a rather unformalized way. Any risk management approach must take into account that SMEs have limited personnel and financial resources and are not willing to carry out high investments.

The business planning of SMEs needs substantial improvement. It is stressed that a comprehensive business planning system is the prerequisite for a sound risk management. A direct link between risk management and business planning is found seldom. Hence most SMEs are not able to determine the total risk position of their enterprise and to estimate the effect of the risks being identified on the target figures for profit and liquidity.

For micro firms and small firms the Balanced Scorecard yet has no meaning. Medium-sized firms, however, are open-minded with respect to it. Despite its well-known weaknesses, the BSC, in connection with business planning, could become an instrument for risk identification and risk evaluation that is suitable for SMEs.

To overcome their deficits with respect to risk management, German SMEs firstly must make an effort to improve their business planning. This is in their own best interests, since in this way they reduce their danger to become insolvent, thus saving their business. In addition, new legal regulations (e.g. Basel II rules; 2003) of SMEs require comprehensive planning systems. It must be emphasized that German SMEs to a large extent are funded externally (Hall, 2004) and that the banks' lending policy makes great demands on the development of the enterprises' business planning.

The questionnaire survey led to interesting results that need further investigation. In 2005 research interviews with some German SMEs will be held to deepen the understanding of the results and to inquire details that a questionnaire survey cannot produce. Special focus will lie on the following aspects:

- How is the business planning organized in detail? If there is a link of planning with risk management: In which form are risks mapped into the business planning?

- What are the reasons for using or not using the Balanced Scorecard? What is the general understanding of this concept and the various possibilities of implementing it?

# **ACTIVATING HIGH-TECH START-UPS: TESTBED AS A MEANS OF SME R&D AND BUSINESS ACCELERATION**

## **Abstract**

The present study used competence block theory to study if an open testbed could accelerate mobile service development, testing and business activities of high-tech start-ups in Finland. In the study it was analysed if the six categories of actors presented by the competence block theory are present in the Octopus actor network and are they taken into account in Octopus service. The analysis showed that in Octopus actor network the customers are poorly present. One of the big problems from the start of the project has been how to get the customers of mobile services to participate in the Octopus project. Innovators are quite well present in the network. The developer companies have very good competence in developing innovative new technological solutions that integrate technologies in new ways. At the start of the Octopus project there were fairly *few entrepreneurs* that would identify profitable innovations and develop them further into marketable service products. After two years of operations these actors were somewhat greater amount and they were more visible to innovators. Competent venture capitalists were virtually non-existent when the project started. After two years the venture capitalist actor category is slightly better present in the network while a few public venture capitalists are begun partnering with the Octopus project. The fifth category, exit markets, is somewhat out of scope of the Octopus project. While not concentrating on finding exit markets Octopus has however in some very few cases helped a service developer to find a new owner for service product. The last category is present as the core partner involvement in the project. The core partner Nokia can be regarded as an industrialist willing to take successful innovations to markets through Nokia's own delivery channels.

## **1. Introduction**

This paper provides an overview of a unique approach to accelerate mobile service development, testing and business activities of high-tech start-ups in Finland. The Octopus program, an open innovation, development and testing environment for mobile applications joins together the needed industrial, educational and governmental players to provide elements needed to bring new mobile services from innovation to business. The core of Octopus is a live testing environment (Octopus test-bed) that can be used by anyone interested in developing mobile services whether it's a company, research institute, individuals or groups of students. In addition to the testing environment, Octopus provides valuable services for its customers and partners. Services, such as

development, testing and business support, cover every phase of product development and launch process. One of the key advantages of Octopus is the open network of actors that cooperate to create added value for the cluster members.

The objective of the present study is to explore value creation in a new and emerging context of technology intensive services. The aim is to understand the value created and perceived by the cluster of mobile service providers, developers and operators. In addition, this study aims at conceptualising the different time-related aspects of value in the specific context of technology intensive services. The research method of the study is explorative longitudinal case study.

Information and telecommunications technology has changed the way people communicate, work and spend their leisure time. Telecommunications and information technologies are converging into a seamless communications infrastructure that is based on IP technology and ubiquitous services. These technologies have brought many new services and applications that people use to either increase productivity at work or enrich their everyday life at spare time. Mobile communications is still mainly voice calls and messaging but the convergence of information technology and mobile communications together with the technological development of mobile phone platforms, communications standards and protocols enable possibilities for new value added services and new business. To take advantage of the emerging markets entrepreneurs, start-ups and pre-established companies need information about the new technological possibilities, service ideas, tools to create and test services and business models.

## **2. Theoretical framework**

The present explorative case study can be described by the competence block theory and model of an experimentally organized economy presented by Carlsson (2003). Companies that develop or distribute mobile services, finance the development or their business is otherwise dependent or

linked to mobile services, constitute a competence block that is driving the mobile service business. Octopus environment can be seen as a safe environment where the new technologies and innovations can be tested without a fear of technological or business mistakes. Octopus is a place for learning, creating competence and using it for business opportunity creation.

Carlsson (2003) also presents six categories of actors that are present in the competence block: 1) customers, 2) innovators, 3) entrepreneurs, 4) venture capitalists, 5) exit markets and 6) industrialists. It is assumed that these categories exist within mobile services competence block and this paper includes a preliminary evaluation of the actor categories that are present in Octopus environment and service network. The evaluation considers only whether the categories are present or not. A deeper analysis of each actor category and evaluation of the how well are they functioning in light of the overall results of the project would be a further study that is yet undone and is therefore not included in this paper.

### **3. Octopus-testbed**

**Origins.** Telecommunications technology, mainly network technology and mobile phones, has for about fifteen years been one of the main industries in Finland. Highest market growth was achieved in the late 90's after which the growth stagnated due to the delay in 3<sup>rd</sup> generation mobile networks and the overpriced 3G licenses in Europe. When telecommunications network infrastructure and mobile phones were not enough to maintain business and economy growth there was a need to develop mobile services and content that would create new business and also drive the investments for 3G mobile infrastructure and mobile phones. The innovative competitiveness of firms and the Finnish ICT-sector would be improved by introduction of previously unavailable mobile services to existing or completely new markets (Rouvinen 2002).

The government of Finland and the city of Oulu share the same interests in increasing

employment and economical growth, and mobile service business have been seen as a great opportunity to increase – or at least sustain – both. Plain market volume and business development has been too slow to take the mobile service business into growth curve therefore there's a need to accelerate the service development. The acceleration effect can be achieved in different ways. The government can e.g. provide funding for industries and companies that have high growth potential or take even more active role. The industry has formed alliances (e.g. 3GPP, Open Mobile Alliance) that aim to create common sets of open standards and protocols that enable developers of mobile services to distribute their applications to the widest possible markets. Large companies with a lot of resources can create their own developer support organizations, processes (e.g. Nokia Forum) and delivery channels.

To accelerate the mobile service business the city of Oulu took the industry initiative and started a partially EU-funded development project with other a few core partners in spring 2002. Three of the core partners were companies: Oulu Telephone Company, Nokia and Technopolis, and one of them was an educational partner: Oulu Polytechnic. The development project aimed at creating and maintaining a live mobile development and testing environment for mobile services that would later become a privately owned company that would cover expenses of its own. The first two years was partially public funded. Other part of funding came from the core partners and customer revenues. In the next chapters the history and properties of Octopus project is described in general, and the challenges met are analyzed.

**The history.** The idea for a development and testing environment for mobile services was born in year 2001. Certain interest groups in Oulu area got together and created a project plan and funding model for an ambitious project, which was later named as the Octopus project. When funding from Northern Finland's Innovative actions EU-program was approved in spring 2002, the project started in September 2002. The first phase of the Octopus project was the pilot phase, which was carried out with five selected pilot customers – various mobile application developers that were

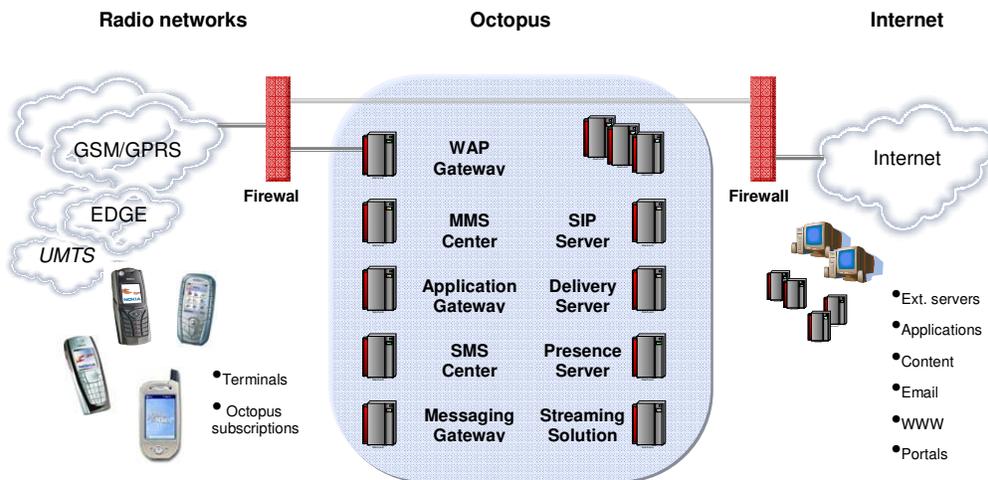

interested in using the Octopus environment to develop and test their services. Pilot phase was necessary for the Octopus project to create and test out the customer processes needed to run an independent mobile testing network. After the successful pilot phase Octopus gained a lot of good publicity in Finland. Marketing of the development and testing environment started and the first customer contracts of the Octopus project were signed during autumn 2003. Also most of the pilot customers signed testing contracts after their successful pilots.

The second phase of the testing environment was up and running in summer 2003 with new technology enablers. After the summer the first success stories were published and the testing network was already in use by many companies, research and educational organizations. The technical environment has been constantly updated with the newest technology to enable the mobile application developers to gain the best possible time-to-market. During the year 2004 one new core partner was announced when TeliaSonera, a northern European teleoperator, joined the Octopus project. By connecting TeliaSonera's radio network to Octopus environment Octopus was able to provide two alternative radio networks and an international coverage for mobile application developers. By the end of the year 2004 there were close to 40 direct Octopus customers and about a few tens of partner organizations in the Octopus network. From year 2005 Octopus continues its' operations with about the same funding structure as before.

**Octopus testing and development environment.** Octopus provides a stable mobile development and testing environment in live radio network that can be utilized by companies, individuals and educational and research organisations developing innovative mobile services and systems. The environment consists of technologies that are already available but also some advanced technologies unavailable in commercial telecommunication networks. The technology is constantly updated with the newest technology to give the developers an edge to their competitors.

The core of the Octopus is the development and testing environment in a live radio network. Octopus technology enablers create a closed cluster of servers (hardware and software) that can be

used with special mobile subscriptions, which have access through the dedicated access point in the radio network and the firewall protecting Octopus servers from unauthorized access. The mobile subscriptions that have access to Octopus servers are called Octopus test subscriptions and these subscriptions don't have access to commercial network services other than GSM and GPRS/EDGE. Connections to and from Octopus subscriptions can only come from other Octopus subscription, Octopus servers or servers connected to Octopus environment. However, with TeliaSonera commercial subscriptions (to which access to Octopus environment have been established) the normal commercial mobile connections together with Octopus testing connections are both available. The above is illustrated in Figure 1.

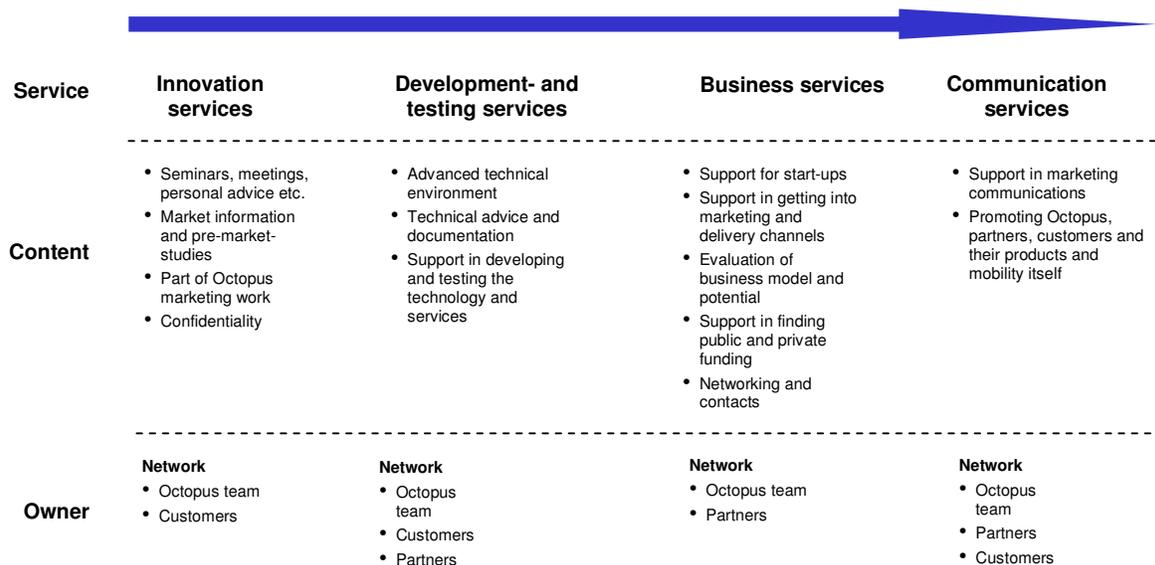

**Figure 1.** Octopus architecture.

In addition to the technology there are also different services that Octopus provides to customers and core partners. Services cover the whole range from idea generation to the product launch. The provider of the services varies depending on the type of service and the subject at hand. Octopus provides testing and development services, which include testing support, configurations

of the Octopus servers, connecting external servers, terminal settings and log tracing for errors. Octopus also provides consultative support for individuals, start-ups and new businesses in starting and developing their mobile business. This is done in cooperation with the wide network of other companies, organisations and the public sector. The Octopus network of actors consists of many local/national/global large/sme companies in the fields of telecommunications, IT, media and other, local and national incumbents, educational and research institutes. Octopus cooperates also with other testing environments, e.g. Rotuaari, DIMES, Testplatz Botnia and NEWT, to bring more possibilities for testing and development activities of the customers. Through deep cooperation with the core partner Oulu Polytechnic Octopus provides training in the field of mobile service development.

Octopus project operations are run by a small group of professionals. The team consists of various types of expertise: technical, marketing, communications etc. in an attempt to cover all the services offered. The network of partners and interest groups are also taking part in the delivery of these services. The figure 2 below summarizes Octopus service portfolio, the contents of the services and the responsible actor for the service delivery.

**Figure 2.** Network of services from innovation to business

**Challenges.** During the Octopus project many challenges have been faced. Most of them are due to the nature of project: starting up and developing something that had not been done before. New technology itself poses many challenges most of which are unexpected. Other challenges are related to funding, operational and service structure, and marketing.

Octopus acts as a pilot operator for Nokia, a world's leading network equipment and terminal vendor. Nokia delivers the newest technology: server software and updates, to Octopus before delivery to commercial operators. Therefore Octopus customers have the chance to develop and test services in an early phase to create a better time to market for their new solutions and/or ensure the functionality of their existing solutions after the update has been done. The new technology upgrades usually don't include training of operation personnel (because there is no training available yet), which requires a lot of time consuming self-learning from the Octopus personnel. Sometimes it is a case of learning it the hard way: trial and error. Also the new technology, especially in the field of ICT, is not always in the "top shape" when introduced into the markets. The incomplete protocols and standards developed by the large communities, e.g. OMA, IETF etc. usually appear as a compromise of the best possible solution and therefore don't always include all the features needed by many particular service solutions. Interoperability issues like service roaming and platform compatibility are very hard to manage by a single equipment vendor, let alone a small software development company. These inadequacies create many particular problems for both the network operators and the service developers.

In developing and testing mobile services the live testing network is a very good to have but it's not enough. The developers need terminals. However, the development speed in the mobile terminals is rapid and it is almost an impossible – or too expensive - task to maintain an up-to-date pool of various terminals that the Octopus customers could use to test their applications. The market leader Nokia alone releases over 50 phone models per year. A pool of testing terminals is not

available through Octopus, however octopus has partially solved the problem by cooperating with a dealer network that is willing to rent commercial phone models to Octopus customers. The not-yet-commercial phone models remain very hard to get for testing purposes even while Nokia is one of the core partners of the project.

At the start of the Octopus project it was not clear what kind of services the customer organizations would need. The start was very technology driven and the emphasis was on the use of the core network and technology enablers. Very soon, during and after the pilot phase, it was found that providing test subscriptions and operating the technical environment was of much smaller importance than expected and the customers needed other types of services. The customers needed many types of information about the new technologies, induction to the technologies and possible service creation opportunities. Also for example, market information about estimated future penetration levels of a particular new technology is of interest. The Octopus service strategy was modified to suit better to the needs of the customers. The services were categorized as (1) innovation, (2) development and testing, (3) business and (4) communication services. The development and testing services is regarded as the core service and the others as value-added services. All the services are available to all customers at a bundled and fixed cost. The categorization of the services is somewhat vague and the services overlap each other. However, that poses no problems as the customer service is carried out in a consultative process that aims to support the customer in a particular business or product development case.

The customer service processes had to be created for Octopus testing environment and many of the processes were imitated from procedures already available. The innovation and business services were carried out in cooperation with a partnering incubator service organization and the processes were already in place. The cooperative processes shaped up on the side. The aim is to facilitate innovation within and across different design spaces (Carlsson 2003) to create new technological possibilities that lead to emerging business opportunities. The communication service

processes needed to be created basically from scratch and required a lot of attention in the start of the project and they have been revised at a few stages when modification has been needed. The provision of test subscriptions and network services was realized through existing processes from the mobile operator operating the environment. However some of those procedures created for commercial telecommunication networks and customers needed many adjustments to fit the needs of a dynamic testing environment and many times the standard way was discarded because the particular issue needed more detailed attention. The dynamic nature of the Octopus services, i.e. ever-changing requirements from the end-customer and a continuous need to develop something new, created a long learning process that is time-consuming but also fruitful. However, after a year of running the Octopus services most of the everyday customer service activities were automated in a manner that could be regarded as repeatable service processes. Still there are many times cases where a detailed look into the subject at hand is needed, and many types of expertise are needed to create the best possible solution.

The goals of the Octopus project in year 2002 were set at a time when the anticipated market growth for mobile services were very high and the industry was starting to recover from the market decline at the start of the century. The ambitious goals for customer acquisition were not reached mainly due to reasonably slower than expected market growth. Also the marketing of the Octopus environment proved a lot harder than expected. A test-bed with new technology enablers that the customer has not previously heard about is not an easy thing to sell, and many times the service developer companies regarded the prices too high or they already used commercial networks for testing their services and did not need the new technology enablers. Last two years there has been a fierce cost-competition in Finnish telecommunication markets, which creates competition for Octopus in terms of cost efficiency. All in all, the test-bed did not sell as well as expected. The marketing challenges were managed by restructuring the service portfolio and creating services to better meet the customer needs. The goals for customer acquisition were modified (reduced) by the

project steering group. Sales and marketing efforts were increased through direct sales and publicity, which paid off at an extent. These efforts have still not been enough to reach the reduced goals. However, the customer satisfaction has been very good every time during the project, which proves that the Octopus customers receive what they pay for.

Funding arrangements for a project like Octopus was not an easy task. The initial funding 5 million Euros was gathered up with a lot of work done by the city of Oulu. Half of the funding was public and the other half came from the core partners. Most of the initial funding was allocated to investments in the testing environment. The annual operational expenses reach almost one million Euros. After two years of project operations the project needed additional funding – as it did not cover its expenses, which was the initial goal, the funding requirements of the core partners increased, and that was not seen as the most pleasant thing. The operation and maintenance of a testing environment like Octopus is very expensive and it also includes some unanticipated costs. The frequent updates and upgrades of the technical environment required e.g. expensive hardware upgrades and software licenses, in addition to expensive software maintenance fees. These costs were not adequately budgeted initially and therefore it created unexpected cost overruns that needed to be covered by the core partner funding. Also the marketing costs of Octopus were budgeted too small. The goals for customer acquisition were set high but the small traveling budget did not serve the purpose. The cost overruns together with the below par realization of the income funding increased the funding pressure from the core partners.

A partially publicly funded development project with so many interest groups: private companies, public financiers, EU-officials, and educational and research organizations, has also many challenges in administration and steering of the project. In addition to the paper work, which had to be done for the public financiers, and operational activities Octopus project had three different steering groups with representatives from all of the core partners. The steering structure was slow and somewhat inflexible not only because of the amount of groups but also because of the

somewhat different interests of the parties involved in funding and steering the project. The slow steering structure and sometimes indecisive steering groups created uncertainty in the operation of the project. However, despite the heavy and bureaucratic steering structure the steering of the Octopus has been surprisingly good. This is mostly due to parties sharing the same main interests; different views have been mainly only in nuances of the issues.

#### **4. Results: Octopus and competence block actor categories**

Carlsson (2003) presented six categories of actors that are present in the competence block: 1) competent and active *customers*, 2) *innovators* who integrate technologies in new ways, 3) *entrepreneurs* who identify profitable innovations, 4) competent *venture capitalists*, 5) *exit markets* that facilitate ownership change and 6) industrialists who take successful innovations to industrial scale production. Following is an analysis of whether these categories exist within the frame of the Octopus actor network and are they taken into account in Octopus service portfolio.

In case of mobile services there are different types of *customers*. Depending on the particular service the customers can be consumers, individual business professionals or organizations in need of mobile tools for their work force. In Octopus actor network the customers are poorly present. One of the big problems from the start of the project has been how to get the customers of mobile services to participate in the Octopus project. The testing environment is mainly designed for service and technology developers and very little can be done to attract e.g. organizations that need mobile services to participate in the project.

*Innovators* are quite well present in the network. The developer companies have very good competence in developing innovative new technological solutions that integrate technologies in new ways. Also the annual competition for mobile services has generated 20-30 new mobile service ideas every year.

At the start of the Octopus project there were fairly few *entrepreneurs* that would identify profitable innovations and develop them further into marketable service products. After two years of operations these actors were somewhat greater amount and they were more visible to innovators.

Competent *venture capitalists* were virtually non-existent when the project started. There were a few core partners and a public incubator that had declared their interest in financing a possible service case that would sound profitable. However, these transactions never occurred during the 1<sup>st</sup> two years. After two years the venture capitalist actor category is slightly better present in the Octopus actor network while a few public venture capitalists are begun partnering with the Octopus project.

The fifth category, *exit markets*, is somewhat out of scope of the Octopus project. While not concentrating on finding exit markets Octopus has however in some very few cases helped a service developer to find a new owner for its' service product. The last category is present as the core partner involvement in the project. The core partner Nokia can be regarded as an industrialist willing to take successful innovations to markets through its' delivery channels. Also a few Octopus customers have delivery capability to mass markets.

## **5. Conclusions**

While the initial targets set in year 2002 were not reached, there are many good visible results of the Octopus project. The concrete and calculable results of the Octopus project after almost two and a half year of operations were a functioning live mobile testing environment with services, a network of 50 organizations (38 customers), hundreds of users testing their applications, 18 commercial mobile services, 10 of them which could be regarded as success stories, 820 attenders of 24 training courses, almost 200 media hits in Finland, many new and maintained jobs and 2 new companies (note: only one third of the companies have reported their results in feedback questionnaires). Many

other positive results may and very likely have occurred but there's little possibility to verify them. Many customers have been pleased with the possibility to reach viable new contacts through networking with the Octopus partners and customers. The effect of this contact creation through Octopus is hard to calculate. It is however very likely that the overall result of the Octopus is more than the sum of its' parts.

At the present moment the Octopus project and environment has been in operation for two and a half years and it serves the customers well – meets the demand of industry and the academic and educational institutes. The project is very expensive but its' impact in the economy and industry remains very little at present. The next strategic step for Octopus would be to become an international mobile service test-bed. The international launch would require a lot of marketing resources, which would mean at least doubling the project budget.

Octopus testing environment competes with the commercial mobile networks for customers and sometimes it is a lot cheaper for the customer to test their services in the commercial network. Is a development and testing environment for mobile services needed? And what would be the prerequisites for this kind of environment? Should it focus on cost efficiency, services or newest technology? How much public funding should be allocated for the test-bed operation and what would be the expected outcome in terms of e.g. new business, employment, payback period? If the public funding covers most of the test-bed expenses, should the test-bed and the services be free of charge to companies and/or educational/research institutes?

**ABSTRACT**

This study uses the case method to interview nine small firms to investigate the costs and difficulties they face when initializing export activity. The sample firms initiated exporting following a reactive strategy; generally responding to customer inquiries, rather than as the result of a carefully planned strategic initiative. None were heavily export oriented. Opportunity costs, especially of time, are significant barriers to exporting or to increasing export behavior. Exporting takes time and energy that is more profitably spent on domestic operations. The sample firms identified transaction costs as problems to be anticipated and overcome, but not as insurmountable barriers to exporting and depended heavily on modern information technology to initiate and support their exporting efforts. The firms were either largely ignorant of governmental export assistance, or had a low opinion governmental export assistance.

## INTRODUCTION

The literature on international entry among small firms is rather detailed, but fragmented. We seem to know a great deal about a variety of factors associated with international market entry. However, we know very little if anything about the costs or processes of developing a foreign market for a small business (Lloyd-Reason, Sear and Mughan, 2003). This conclusion is startling when one considers how far our knowledge of international activities among small firms has come in the last twenty years.

The importance of exporting by small firms cannot be understated. A research report conducted by the International Trade Administration (2003) indicates that 230,736 small and medium-sized firms (companies with fewer than 500 workers) exported goods in 2001. Small and medium-sized companies account for 97 percent of U.S. exporters, a percentage that has only varied slightly since 1995. These firms exported goods valued at \$182 billion that represented 29.2% of total U.S. goods exported.

The purpose of this study is to investigate the costs of developing a foreign market for a small business. A variety of issues have been considered within the literature on exporting by small businesses. Yet, researchers and public policy officials continue to struggle with the identification of the factors or barriers that may raise the costs of foreign market entry by small firms. Though the present research examines motivation for entry into international markets, the costs of entry, the process of entry, and firm size, this research primarily examines the transaction and opportunity costs of exporting--both out-of-pocket costs and the psychological costs. The psychological costs include fear of the unknown and the opportunity costs of acquiring new market and operational information. Thus, the research questions of this study are: What is the primary motivation for small U.S. firms to begin exporting to foreign markets? What costs do small firms incur when they initially seek to export? What is the magnitude of exporting costs relative to the firm size? Which of these costs inhibits the small firm from exporting? How might the U.S. government better assist small firms to overcome these costs? This study uses the case method to evaluate the export practices of nine small firms in South Carolina, using CEO/VP interviews and secondary company information to augment the interview findings.

## LITERATURE REVIEW

An attempt to gain an understanding of small firms has emerged as an important research issue in the past quarter century. Rather than attempt an exhaustive review of past research, this section will emphasize the dominant research relevant to small firm foreign market development.

### **Motivational Factors**

Czinkota and Tesar (1982) find that motivation can be categorized into proactive and reactive categories. Proactive reasons are based on the firm's internal situation and are firm initiated, while reactive reasons are based on the firm's behavior with respect to the environment and are in response and adaptation to changes from outside the firm. Firms

with proactive motivations go international because they want to, while reactive firms go international because they must. Pope (2002) finds that very small firms export because they have a unique product or a technological advantage. Larger firms export also to achieve economies of scale and to avoid losing foreign opportunities. The major conclusion is that proactive motivations dominate when pursuing exporting. However, the literature has focused largely on the motivations of larger firms. It is possible that small firms have a different rationale for selling in foreign markets. Thus:

*Research Question 1. What is the primary motivation for small U.S. firms to begin exporting to foreign markets?*

### **Costs – The missing variable**

The literature does not document the costs associated with expansion into international markets especially well. The actual costs of foreign market entry may be critical, because of their relative magnitude to small firms compared to larger firms. Wright (1993) reports that both personal costs and personnel costs should be considered before deciding whether to export and points out that these questions may lend themselves to a case-based smaller-sample approach.

Perhaps the most promising research on costs comes from Economics. The costs of international transactions generally are far from negligible (Abdel-Latif, Abla M. and Jeffrey B. Nugent, 1996, p. 1). Transaction costs include information costs, contracting costs, delivery and payment costs, and control and enforcement costs (Williamson, 1971 and 1981). International transaction costs tend to be much higher than domestic transaction costs due to language, cultural, and legal differences, and the inherent difficulties of enforcing contracts overseas (Kim, Nugent, and Yhee, 1997). The literature uses transaction cost economics (TCE) to evaluate the small firms' export efforts (Kim, Nugent, and Yhee, 1997; Abdel-Latif, Abla M. and Jeffrey B. Nugent, 1996). In international research, TCE has been used to describe the mode of entry rather than whether transaction costs prevent small firm entry. Thus, TCE has been limited in its ability to identify the magnitude or relative importance of transaction costs. Thus:

*Research Question 2. What costs do small firms incur when they initially seek to export?*

A proactive motivation to export will likely result in different costs than a reactive motivation. The literature emphasizes out-of-pocket transaction costs (Atherton and Sear, 1997; Abdel-Latif, et. al., 1996). This study examines the out-of-pocket costs, but also any psychological, personal, or opportunity costs that may emerge.

*Research Question 3. What is the magnitude of exporting costs relative to the firm size?*

In order to determine the expected value of an entrepreneurial endeavor in a foreign market, the owners or managers of a small firm must evaluate the costs of the opportunity. Transaction costs of international market entry may be so large for some

small firms because some costs of exporting are fixed and thus may be prohibitive to a small firm.

*Research Question 4. Which of these costs inhibits the small firm from exporting?*

Pursuing an overseas opportunity requires analysis and may require both formal planning (Olson and Gough, 2001) and informal planning (Atherton and Sear, 1997). In this assessment process, one would expect the firm's strategists to identify those costs that are the most difficult obstacles to overseas expansion.

*Research Question 5. How might the U.S. government better assist small firms to overcome these costs?*

The U.S. government offers a variety of programs to assist American companies seeking to export their goods and services (Moini, 1998). Thus, an underlying theme of this research must be the public policy implications of the findings. In their work in the United Kingdom, Atherton and Sear (1997) and Lloyd-Reason, Sear, and Mughan (2003) point out that potential problems with government assistance programs arise due to incomplete understanding of the government assistance process.

## **RESEARCH METHODOLOGY**

This research uses a case-study method as a valuable qualitative research strategy (St. John and Heriot, 1991; Abdel-Latif and Nugent, 1996; and Rialp-Criado, Urbano and Vaillant, 2003, Audet and d'Amoise, 1998). Thus, the case-based methodology is applicable to the understanding the development of a foreign market.

### **Interview Firms**

A list of small firms was provided to the researchers by the South Carolina Export Consortium, a not-for-profit organization that assists companies with international trade issues. As the literature recognizes the unique differences between small firms that have an ongoing export strategy and those that are deciding whether to export or not, we made every effort to select a broad, cross-section of small firms that were engaged in exporting. Most of the firms were fairly new to exporting while other firms had considerably more experience with exporting. Nine firms were carefully selected to ensure that both manufacturing and marketing firms of different sizes were chosen. They were selected in such a way that should make them differ, though by *a priori* predictable reasons, along key dimensions previously developed according to our literature review. The researchers interviewed the founder, CEO, or other senior officer of the small firm. These individuals are directly responsible for the strategic direction their companies pursue. They possess direct knowledge of their company's experience.

## **Analysis**

We collected data from several information sources (in-depth interviews with senior managers deeply involved with international decision-making processes, company websites, internal and external documentation, product and firm brochures, and other secondary data). The nine case studies were cross-analyzed to identify generalizations from firms with similar theoretical conditions. According to Yin (1998), analytical – not statistic - generalization of the results of the several cases being used can be obtained.

## **RESULTS**

The researchers asked a series of 39 questions to senior management of each of the nine firms. The questions in the instrument are divided into five sections: the firm's background, exporting experience, product information, target market information, and feedback on costs and barriers of exporting, as well as feedback on exporting assistance. Because of space constraints, only a summary of the answers to the questions relating to exporting experience of the nine firms is reported in Table 1.

Table 1 About Here

---

## **DISCUSSION**

The purpose of the proposed research was to investigate the barriers to foreign market entry by small U.S. firms. The basic premise was that identifying these barriers would better help the researchers identify the costs of internationalizing. By identifying these costs, advice could be provided to small business owners seeking to export. Policy makers could also use this information to better assist small business owners through training programs and other forms of public assistance.

Most of the firms in this study could be categorized as reactive in their motivations. Their stimuli for exporting were usually in response to unsolicited orders which required them to follow-up on the lead. Their motivations to export were not necessarily indicative of aggression. Yet, it is not surprising that these firms were not pursuing exporting with greater commitment or enthusiasm when one recognizes just how small these firms were. They have very little time to emphasize both domestic and prospective international firms, so they emphasized their current operations.

Despite the differences among the firms and the characteristics of their products, each of the firms emphasized extensive use of the Internet for communication and international marketing activities. Some firms developed extensive web sites for their customers while other firms relied on e-mail to communicate with overseas customers. The introduction of the electronic mail via the Internet and the use of websites to promote products and to conduct business transactions have changed the nature of distribution and marketing for some firms.

A firm that develops a web site is not directly soliciting orders from customers, but is allowing potential customers to easily contact them. The Internet affords these firms the opportunity to bypass traditional distribution channels in order to directly communicate with the customer while also avoiding significant costs. Today, firms with an Internet site have the ability to be contacted by many more prospective customers regardless of their relative locations, but the percentage of sales closed will be much lower than from personal sales. However, the much larger number of potential sales multiplied by the lower closer percentage may result in larger sales. The firms in this study seem to be trying to capitalize on the benefits of the Internet.

A fundamental issue in strategic management is to know your target market. The firms do not have a clear understanding of their top international markets or do not have adequate business plans to reach the markets. This points to the opportunity costs these firms have due to their lack of resources (time and personnel). The participants in this study clearly had to overcome opportunity costs that prevented them from devoting time, their most valuable resource, to the process of exporting. Transaction costs such as packaging, travel, customs clearances, shipping and logistics appear to be challenges, rather than insurmountable barriers to market entry. Opportunity costs were much more of an issue for these small firms.

## CONCLUSIONS

This section reviews the findings as they specifically relate to each of the research questions that guided this study.

*1. What is the primary motivation for small U.S. firms to begin exporting to foreign markets?*

The firms interviewed were generally reactive and entered the export market in response to inquiries from potential customers because they are small and do not have the time to be proactive. One firm said, "They will find me. They know how to find me better than I know how to find them."

*2. What costs are incurred by small firms when they initially seek to export?*

For the firms in this study, out of pocket costs do not appear to be the primary barrier to exporting. Rather, psychological, personal, and opportunity costs were more important barriers. For example, a small retailer showed the researchers how difficult and time consuming it is to properly prepare labels for international shipments of small orders. This study found that opportunity costs were profoundly important to the small firms.

*3. What is the magnitude of exporting costs relative to the firm size?*

Transactions costs of international market entry may be so prohibitive for some small firms because certain costs of exporting (primarily start-up) are fixed and thus may be prohibitive to a small firm. For example, the largest firm in our study discussed how

important it is to efficiently pack shipping containers to maximize the amount of goods that can be shipped. It took some time to learn this skill.

#### *4. Which of these costs inhibits the small firm from exporting?*

This research study found that psychological, opportunity, and personal costs were the largest barriers to exporting. Several firms expressed concern that if they pursued overseas opportunities, U.S. opportunities would be forgone. Psychological costs were also an issue. In this regard, uncertainty seemed to be the most critical psychological barrier. One of the firms had uncertainty over how to pursue his international efforts. “We are struggling to get to the next level – international. The problem is finding the right alliance to do that.” Typical transaction costs, including logistics, travel, shipping etc., were discussed, but not emphasized as barriers that could not be overcome.

#### *5. How might the U.S. government better assist small firms to overcome these costs?*

Most small firms tend to be reactive as they respond to international sales opportunities rather than proactively seek them, especially in their initial approaches to foreign markets. In spite of the reactive nature of many small firms, their sheer percentage of the overall export market suggests that existing government export promotion programs should pay attention to them. In order for these government programs to assist small exporters, they need to have a better understanding of the nature of small exporters. Thus, government export promotion programs should tailor their programs to meet the unique needs of these small firms.

### **Limitations**

This research did have one major limitation that should be noted. This study clearly used a small number of respondents, which prevents generalization usually sought in more objectivist research. However, the primary goal of this research was to explore in depth the issues associated with barriers to foreign market entry.

### **Summary**

Using a case method, this study gathered detailed feedback from nine small firms in South Carolina that have begun exporting their goods to foreign markets. The feedback from the CEOs of these firms suggests that **psychological, personal, and opportunity** costs such as the time it takes to learn how to perform the logistics of exporting and overcoming the fear of exporting are often more important than the out-of-pocket costs of exporting. Thus, this study argues that researchers and public policy makers would be better served by developing a process to communicate information to small firms so that the firms can more effectively export.

ANALYSIS OF FACTORS INFLUENCE THE PERFORMANCE OF  
INDONESIAN SMALL AND MEDIUM ENTERPRISES  
(A RECOURSE-BASE THEORY APPROACH)

Abstract

This research is aimed at explaining the relationship based on resource-base theory and contingency theory used in developing research framework. Specifically, the relationship is between personality values, business strategy, environmental uncertainty, and firms' performance. The three hundreds (300) respondents who are entrepreneurs from various manufactures of small and medium companies in Indonesia have been used to test research hypothesis. Based on hierarchical regression, it can be concluded that business strategy is mediating variable on the relationship between entrepreneur's personality values and firms' performance, and environmental uncertainty is moderating variable towards the relationship between business strategy and firms' performance.

**Introduction**

Small and medium enterprises (SME) play an important role (Yu, 2001), therefore they dominant the most number of firms in the world, both in developed and developing countries (Day, 2000; Wijewardena & Tibbits, 1999; Sanjaya, 1997). The role of SME is more important in developing country, especially for Indonesia (Swasono, 1986). The development of SME has brought some positive impacts although they haven't been able to change Indonesian economic structure as a whole (Marzuki, 1997; Tambunan, 1999). However, there are still some findings about SME bankruptcy while some SMEs are very success running their business instead.

The influences of factors on firm's success are different from one country to another country. The differences are due to economic condition, location, and culture (Wijewardena & Tibbits, 1999). Some researches have found that factors determining bankruptcy also influence the firm's success (Gaskill, Auken, & Manning, 1993). Previous researches have not explained comprehensively the reasons of bankruptcy of many firms (Gaskill et al., 1993). Researchers often used rational theory (Jennings & Beaver, 1993), and there have not unified theoretical model that explain factors influence SME's performance (Kangasharju, 1997).

Research on the success of IKS may use four approaches, they are (1) personality approach, (2) business management approach, (3) sectoral approach, dan (4) organization development approach (Gibb & Devis, 1990). This research will focus on personality characteristics of an entrepreneur because personality characteristics of an entrepreneur are often used as the base on many previous studies (Bab & Bab, 1992). Some researches have found personality characteristics of an entrepreneur are an important factor that influences firm's performance (Luk, 1996; Theng & Boon, 1992; Ibrahim & Goodwin, 1986; Montagno, Kuratko, & Scarcella, 1986). However, many previous researches relate directly between personal characteristics and firm's performance.

Based on resource-based theory, the influence of personality factor towards firm's performance is not only directly but also indirectly, that is, through the application of business strategy. Therefore, this research has purpose to examine the influence factors on SME's performance by applying resource-based theory as a base in developing research framework. Besides, this study also uses contingency theory to explain the influence of environmental uncertainty towards firm's performance.

## **LITERATURE REVIEW**

### **Theory**

Resource-based theory explains that firm's sources are the main factor that determines competitive advantage and profitabilities (Michalisin, Smith, & Kline, 1997; Bates & Flynn, 1995; Mahoney & Pandian, 1992). One of the unique sources that possibly possessed by firm are personality values of an entrepreneur. Personality values will influence business strategy that result competitive advantage. Therefore, SME's performance will also be influenced by environmental uncertainty, therefore this research will use contingency theory to explain the relationship between business strategy and firm's performance..

### **Personality, Strategy, and Performance**

Some previous research found that personality characteristics and managerial skills of an entrepreneur is critical factor on SME's performance (Al-Shaikh, 1998; Box, White, & Barr, 1993; Cragg & King, 1988). However, until at present there has not a universal agreement on the scope of managerial field (Cragg & King, 1988). Management and planning functions have overall characteristics and included in all aspects in business (Gaskill et al., 1993). As a result, the difference between one researcher to other researchers is sometimes using different focus of personality and managerial.

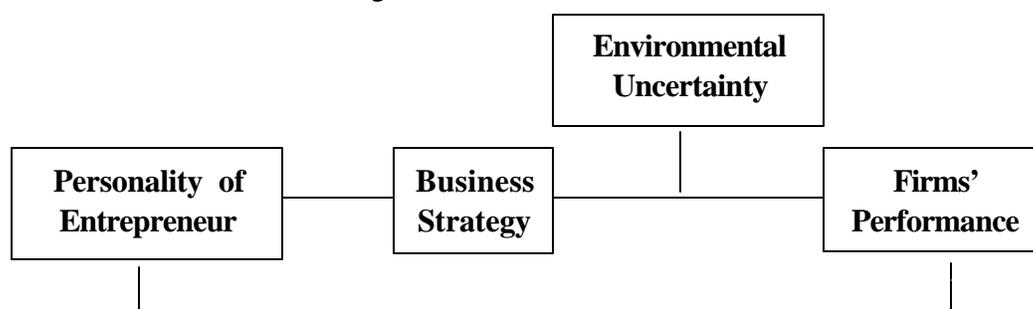

Research conducted in Indonesia found that need for achievement and locus of control are the main personality characteristics comparing to other entrepreneur's personality characteristics (Riyanti, 2003; Sukardi, 1991). Pandey and Tewary (1979) stated that both personality characteristics are important and main entrepreneurship values. Therefore, this study will focus only on two personality characteristics, they are, need for achievement and locus of control.

Research conducted by Miller and Toulouse (1986) found that there is correlation between need for achievement and locus of control with business strategy as well as on firms' performance. Research conducted by Kotey and Meredith (1997) indicated that one who has high entrepreneurship characteristics will use more proactive strategy and apply that strategy in the firm and therefore firm will gain higher performance. Research focuses on locus of control conclude that locus of control has positive relation with business strategy and as a result it will influence firm's performance (Boone, Brabader, & Witteloostuijn 1996; Nwachukwu, 1995).

### Research Framework

Based on resource-based theory and contingency theory, and findings on previous studies, this research framework can be diagrammed as follows:

Figure 1. Research Framework

### Hypotheses

Based on the literature review and research model therefore the hypotheses of this research are:

Hypothesis 1: Business strategy is mediating variable that relates between personalities of entrepreneur and firms' performance

Hypothesis 2: Environmental uncertainty is moderating variable that relates between business strategy and firms' performance.

## RESEARCH METHOD

### Population and Sample

The size of SME used in this research is firms that have the numbers of employees from 1 to 99 (BPS, 2002). Data selection of firms found in Directory of Manufacturing Firms in 2001 found 15.593 firms categorized as SME. Four provinces as the center of medium manufacturing firms in Indonesia, they are, DKI Jakarta, West Java, Middle Java, and East Java with the numbers of firms 12.326. These four provinces are approximately representative of small and medium size of manufacturing firms in Indonesia.

Due to the limitation of time and cost therefore sample was selected by purposive random sampling to 300 firms. Since the list of sample frame address was not available, technique “*snow ball*” is used in selecting sample, that fulfill the criteria outlined by the definition of SME according to Central Bureau for Statistics in Indonesia.

## **Variable Measurement**

### ***Need for achievement***

Need for achievement construct was adopted from Steers and Braunstein (1976), this is a common practice for similar studies that conducted earlier such as Entrialgo, Fernandez, and Vazquez (2000), Box, et. Al (1993), and Miller and Toulouse (1986). The measurement used to measure this variable consisted of five items, and the seven-point likert-type scale (from 1 to 7) were used for the purpose of this study.

### ***Locus of control***

The measurement of locus of control that developed by Rotter (1996) and modified by Lumpkin (1985) has been used for this study. However, the Lumpkin (1985) modified measurement was recognized and used by many researchers such as Entrialgo et al. (2000) and Box, et.al (1993), and thus, in a line with the previous research, this study will use the modified measurement of locus of control. This measurement as modified by Lumpkin (1985) consists of two categories, namely, high internal locus of control, and low internal locus of control, each of which have three items. Seven points Likert-type scale ranging from 1 to 7 will be used for the purpose of this study.

### ***Business Strategy***

The Strategy Hierarchy comprises with corporate level, strategic business unit level, and functional level. The measurement of business strategy is based on functional strategy has been used by Kotey and Meredith (1997) and Gadenna (1998). The questionnaire on functional strategy consists of 36 items, including production strategy, marketing strategy, financial strategy, research and development strategy, and human resource strategy. Measurement is conducted by using Likert scale, that is, 1 to 7.

### ***Environmental Uncertainty***

Environmental uncertainty will be measured by using questionnaire developed by Miles & Snow (1978). The measurement used some questions related to environment dimension such as: marketing condition, government policy finance, labor and competition. The measurement uses Likert scale from 1 – 7 (from very predictable to very unpredictable). From the questionnaire acquired some values which describe perception of manager owner of SME toward environmental uncertainty, the higher the value, the higher the environment uncertainty.

## *Firms' performance*

An extensive literature review of 52 empirical research on entrepreneurship were conducted by Murphy et al. (1996), they concluded that five measurements of firms' performance were used frequently in this area of research, these are: sales growth, profit margin, return on investment, return on equity, and return on asset. Therefore, this research intends to utilize three out of these five measurements, namely, sales growth, profit margin, and return of asset. The respondents of this study will be requested to indicate their firms' average of these performance measurements for the last three years. Furthermore, in order to obtain total firms' performance measurement, the average of these three performances measurements was calculated and named as financial performance, this procedure is similar to that used by Boone, et al. (1996).

## **Method of Analysis**

This research used some statistical analysis methods to assist data analysis and hypothesis testing. Before applying regression analysis, analysis factors analysis and reliabilities were conducted firstly. Based on the concept of analysis on mediating variable proposed by Baron and Kenny (1986), and Ndubisi, Jantan, and Richardson (2001), hierarchical regression model used to test first hypothesis is:

$$Z = a + b_1 X_1 + b_2 X_2$$

$$Y = c + d_1 X_1 + d_2 X_2$$

$$Z = e + f Y$$

$$Z = g + h_1 X_1 + h_2 X_2 + j Y$$

### Full Mediating

- $b \neq 0$
- $d \neq 0$
- $f \neq 0$  also  $j \neq 0$
- $h = 0$

### Partial Mediating

- \*  $b \neq 0$
- \*  $d \neq 0$
- \*  $f \neq 0$  also  $j \neq 0$
- \*  $h \neq 0$  but  $h < b$

To test the second hypothesis, the following model is used:

$$Z = e + f Y$$

$$Z = e + k_1 Y + k_2 M + k_3 YM$$

where:

- X1 = Need for achievement
- X2 = Locus of control
- Y = Business strategy
- Z = Firms' performance

M = UnvIRONMENTAL uncertainty

YM = Interaction business strategy and unvIRONMENTAL uncertainty

## FINDING

### Samples Characteristics

The result of descriptive statistic of the characteristics of firms' samples can be seen in Table 1, and the characteristics of entrepreneurs' samples can be seen in Table 2.

Table 1  
Firms Profile

|            |                     | Total | Percent |
|------------|---------------------|-------|---------|
| Location   | West Java           | 80    | 26.67   |
|            | Middle Java         | 70    | 23.33   |
|            | East JAva           | 80    | 26.67   |
|            | DKI Jakarta         | 70    | 23.33   |
| Legal form | Limited corporation | 62    | 20.7    |
|            | Commanditor         | 48    | 16.0    |
|            | Proprietorship      | 110   | 12.7    |
| Age        | ≤ 10 tahun          | 151   | 63.3    |
|            | >10 – 20 tahun      | 107   | 35.7    |
|            | > 20 tahun          | 42    | 14.0    |
| Employee   | ≤ 19                | 229   | 76.3    |
|            | > 19 - 99           | 71    | 23.7    |

Following are the entrepreneur's characteristics of this study

Table 2  
Entrepreneur profile

|             |                      | Total | Percent | Mean | Standard Deviation |
|-------------|----------------------|-------|---------|------|--------------------|
| Age (years) | ≤ 40                 | 180   | 17.0    | 39.2 | 9.9                |
|             | > 40                 | 120   | 46.6    |      |                    |
| Sex         | Male                 | 236   | 78.7    |      |                    |
|             | Female               | 64    | 2.3     |      |                    |
| Education   | ≤ Junior high school | 69    | 23.0    |      |                    |
|             | Senior high school   | 160   | 53.3    |      |                    |
|             | Diploma              | 30    | 10.0    |      |                    |
|             | Bachelor             | 41    | 13.7    |      |                    |

|                                 |          |    |      |      |     |
|---------------------------------|----------|----|------|------|-----|
| <b>Length of tenure (years)</b> | ≤ 5      | 61 | 29.6 | 15.7 | 7.3 |
|                                 | > 5 – 10 | 52 | 25.2 |      |     |
|                                 | > 10     | 49 | 23.8 |      |     |

### **Validity and Reliability**

To test the validity to the measurement, factor analysis was conducted, and the reliability of the measurement can be seen from its Cronbach Alpha. The measurement is reliable if its' Cronbach Alpha is at least .60. Moreover, loading factor is equal or more than to .3 is accepted, and cross loading equal or more than to 0,3 is rejected (Hair, Anderson, Tatham, & Black, 1998).

Factor analysis towards instrument of entrepreneur's personality characteristics results 3 factors, named as locus of control, need for achievement, and risk taking. Factor analysis to instrument of environmental uncertainty results four factors, which can explain 72,19 varians factor formed. The second order of factor analysis towards mean factor formed results one factor only, consists of 17 items and expains environmental uncertainty. Factor analysis on business strategy instrument results five factors, consist of 30 items. The second order of factor analysis towards mean factor formed results one factor, called business strategy.

### **Test of Hypotesis**

Testing on the first hypothesis is conducted through 3 stages of regression. The first stage is to test relationship between entrepreneur's personality values and business strategy. Second is business strategy and firms performance. Third stage is conducted through hirarchical regression, that is the relationship between personality values and firm's performance, and so forth between personality values and business strategy and firm's performance. The summary of regression analysis can be seen in Table 3.

Table 3 indicates that model 1 can explain the positive influence of personality values towards business strategy ( $R^2 = 12.8$ ,  $F = 14.336$ ,  $p \text{ value} = .01$ ). This means that 12.8 percentage of varians of business strategy can be explained by personality values of an entrepreneur. Partial analysis also indicates that all dimensions of personality values of an entrepreneur have positive influence towards business strategy. Therefore, either simultaneously or partially, personality values of an entrepreneur can contribute towards the formation of business strategy.

In Table 3, the influence of business strategy towards firms' performance can be seen. The ability of business strategy to explain firms performance is moderately high, that is, 19.2 percent. Three dimensions of personality values of an entrepreneur, locus of control, risk taking, and need for achievement are able to explain 25.8 of varians of firms performance. The ability to explain the varians of firm's performance is higher if in regression analysis of personality values, business strategy is added. Personality values and business strategy are able to explain 34.6 percent of the varians of firm's performance.

Partially, locus of control, risk taking, and need for achievement have positive influence towards firm's performance. Similarly, business strategy also has positive influence towards firm's performance. If standardized coefficients ( $\beta$ ) of personality values and business strategy are compared, it can be concluded that locus of control and business strategy have ability to explain the higher varians of firm's performance comparing with need for achievement and risk taking.

All of analysis requirements on mediating variable explained by Baron and Kenny (1986) can be fulfilled in testing conducted. Standardized coefficients ( $\beta$ ) of locus of control, risk taking, and need for achievement indicate the decreasing between before and after business strategy is added in the equation of regression. Therefore, business strategy is partially mediating variable towards the relationship between locus of control, risk taking, and need for achievement and firms' performance.

Table 3.  
Business Strategy is Mediating Variable

| Independent Variable    | Business Strategy |          | Firms' Performance |          | Firms' Performance |          | Firms' Performance |          |
|-------------------------|-------------------|----------|--------------------|----------|--------------------|----------|--------------------|----------|
|                         | b                 | T Value  | b                  | T Value  | b                  | T Value  | b                  | T Value  |
| Locus of Control        | .116              | 2.050**  |                    |          | .382               | 7.356*** | .327               | 6.573*** |

The second of hypothesis testing is conducted by using hirarchical regression. This is conducted after forming interaction variable between business strategy and environmental uncertainty. The result of testing on the influence of environmental uncertainty as moderating variable towards the relationship between business strategy and firms' performance can be seen in Table 4.

Table 4 indicates the ability of business strategy in explaining higher varians of firms' performance after inserting the variable of environmental uncertainty to the equation of regression, that is, 19.2 percent to 22.2 percent. Partially, the influence of business strategy is positive towards firms' performance, but the influence of environmental uncertainty is negative. This means that busines strategy implemented by firm

will motivate firms' performance, however environmental uncertainty will weaken the achievement of good firms' performance.

If variable interaction between business strategy and environmental uncertainty is added into regression equation, the result of regression shows that interaction variable is able to explain the change in firms' performance significantly (F Change =2.974 at p= .1). Therefore, it can be concluded that environmental uncertainty is moderating variable towards the relationship between business strategy and firms' performance.

Table 4.  
Environmental Uncertainty is Moderating Variable

| Pembolehubah Bersandar Non Standard Change? | Firms Performance |          |           |           |         |          |

## DISCUSSION

This research result indicates that business strategy is partially mediating variable between personality values and firms' performance. This means that firms' performance is not only influenced directly by personality values but also influenced by business strategy. This research finding support previous research conducted by, like Boone et al. (1996), Nwachukwu (1995), Entrialgo et.al (2000), and Kotey and Meredith (1997).

In accordance with personality values of an entrepreneur, that is, dissatisfaction with what he has gained, always enhance his performance, highly confidence on his job, risk-taking, therefore these values will influence him in the implementation of business strategy related to environmental condition faced with. Therefore, personality values will also give positive influence towards the implementation of business strategy, and, so forth, competitive advantage and profitabilities can be achieved.

The competitive advantage formed through personality values will face negative influence from

environmental uncertainty. This research finding indicates that the relationship between business strategy and firms' performance will be moderated by environmental uncertainty, in which, the environmental uncertainty weakens the relationship between business strategy and firms' performance. Some previous research supports this research, some of them are conducted by Kumar and Strandholm (2002), and Herri (2002).

## CONCLUSION AND SUGGESTION

Internal factors such as personality of entrepreneur and business strategy have contribution to SMES's performance. High performing SMEs tend to have proactive strategy, internal locus of control, high need for achievement, and risk taking. Higher environmental uncertainty influenced by long lasting economic crisis in Indonesia results negative influence towards SMES's performance.

### Implication

This research gives contribution to evaluate the practice of SMEs management, and is made as basis for compilation of policy. This also adds research related to aspects determining SMEs performance. Among its implication is the importance of developing of nature of entrepreneurs giving contribution to SMEs performance like nature of locus of control, need for achievement, and risk taking. Besides, the development in the implementation of appropriate business strategy to environment condition is necessarily performed so that high firms' performance can be achieved.

### Future Research

To support this research finding, future research may be conducted by modifying into some other characteristics. The possibility to include cultural factor or ethnic may be also performed since this factor probably also influences SMEs' performance.

Most of samples are coming from manufacture sectors, for future research, it is possible to have research in different sectors such as trading or service hence it will broaden the knowledge about the factors contribute to the performance of SMEs in Indonesia. Moreover, data of this research merely come from the perception of the respondents; research by using an objective data is one of the possibilities in the future.

Paper to be presented at the ICSB World Conference, June 15-18, 2005

*“Golden Opportunities For Entrepreneurship”*

### **ABSTRACT**

This exploratory study focuses on the possible relation between innovation and international involvement of SMEs. Some studies have suggested that innovation has a positive impact on the likelihood of enterprises to internationalise their business activities. We have tested this proposition using indicators for innovativeness that are specifically developed for SMEs and focusing on exporting as well as importing activities of enterprises. The results of our study suggest that there is a significant positive effect of several measures for innovation on international involvement. The results are based on a representative sample of more than 1.800 Dutch SMEs using logistic regression analysis.

**Keywords:** internationalisation, innovation, SMEs.

## **INTRODUCTION**

The aim of this study is to explore whether a link exists between innovativeness of enterprises and internationalization (imports and exports). Research into internationalization of SMEs used to be primarily focused on exports. In recent years however it is increasingly acknowledged that exporting and importing are interrelated processes and there is more attention in research for imports and other inward modes of internationalization (e.g. Korhonen, 1997; 1999; Liang & Parkhe, 1997).

It is known that access to know how and technology is an important motive for SMEs for internationalizing their business activities (European Commission, 2004). A number of studies have explored the relationship between internationalization and innovation. These studies mainly focus on the relationship between innovation and export. Also indications can be found that a relation exists between innovation and import. For example, the results of one study reveal that SMEs that import are above average importing innovative (new) products (Van de Graaff and Overweel, 2002). Therefore it was decided to include imports as well as exports in the analysis.

Innovativeness is assessed by a number of indicators for innovativeness, such as the recent introduction of new products or services, the recent introduction of new or improved internal business processes and inter-firm co-operation. International involvement is defined as being involved as a firm in exporting and/or importing activities. It is examined whether a positive relation exists between innovation and international involvement of the enterprise. A distinction is made between enterprises that only export, enterprises with both exports and imports, and enterprises that only import. The analysis is based on SMEs located in the Netherlands. The data relate to a representative sample of Dutch SMEs. Elaborating on existing research into innovativeness of SMEs indicators for innovation will be used that are specifically developed for SMEs.

## **LITERATURE ON INNOVATION AND INTERNATIONALISATION**

### **Innovation of SMEs**

Innovation involves targeted renewal of products, services or working methods. Entrepreneurs innovate in order to be able to better address the demands of customers, to improve their competitiveness or to achieve better financial results for their businesses. For this reason innovation is as important for small enterprises as it is to large firms (Van de Graaff and De Jong, 2004). However, there are a number of differences with respect to the way innovation takes place between SMEs and larger enterprises. For example, SMEs traditionally have more limited resources for conducting R&D. Also, innovation is often less formalized in smaller enterprises. However, on the other hand SMEs are more flexible than larger firms, which enables them to respond quickly to changes in the environment. For this reason SMEs are often successful in developing new product-market combinations and in adapting products to the demands of niche markets or individual customers (Bernardt, 2001). These differences between small and larger enterprises affect the ways in which innovation is measured in SMEs. Many traditional indicators of innovation, such as expenditures on R&D are not very useful in measuring innovation in SMEs. That is why specific indicators have been developed for measuring

innovativeness of SMEs (Van de Graaff and De Jong, 2004). In this study we will focus on these indicators that are specifically developed for measuring innovativeness of SMEs.

### **Internationalisation of SMEs**

Traditionally, research on internationalization of enterprises is strongly focused on large multinational enterprises. Currently there is more attention for SME internationalization since it is recognized that SMEs are increasingly involved in international markets (European Commission, 2004). Studies on the internationalization of SMEs were traditionally mainly focused on export activities (e.g. Bloodgood *et al.*, 1996; McDougall and Oviatt, 1996). More recently there is more attention for imports and other inward modes of internationalization in internationalization research (e.g. Korhonen, 1997; 1999; Liang & Parkhe, 1997). It is increasingly acknowledged that imports may be important for national economies, for example because imports may contribute to the upgrading of national products or services.

Research has found that the majority of internationalized enterprises are involved in outward (e.g. export, foreign direct investment) as well as inward (e.g. import) international activities (Fletcher, 2001). The majority of Dutch SMEs that are involved in exporting activities, for example, are also involved in importing activities (Hessels *et al.*, 2005). It is increasingly recognized that inward and outward modes of internationalization are interrelated processes (Korhonen, 1999; Van De Graaf and Overweel, 2002). For example, the step to start exporting may be smaller when an enterprise already imports goods or services from abroad. The reason for this is that an enterprise that imports already has business contacts in foreign countries, and thus maintains a channel to the foreign market through which it gets information about this market. In this study inward (imports) as well as outward (exports) modes of internationalization are included in the analysis.

### **Innovativeness and internationalization of SMEs**

There are several reasons for presupposing that innovativeness will influence the internationalization of enterprises. First of all, product and process innovations may make it possible for enterprises to target new markets. The potential market for products of innovative firms may be much wider than is the case for less innovative firms (Autio *et al.*, 2000). Normally, innovation efforts will result in improved, modified or new products that may give enterprises a (temporary) competitive advantage in foreign markets (Van Dijken and Prince, 1997).

Furthermore, improved or renewed business processes make it possible for firms to adapt or innovate products, to increase the speed of the production process and to reduce costs (Van Dijken and Prince, 1997). The acquisition of new process technology may stimulate enterprises to review or revise their strategic direction and market focus (Bell *et al.*, 2004). This may stimulate enterprises to undertake international business activities or to accelerate their internationalization process. In addition, innovative firms often have to anticipate competitive responses which may stimulate them to make international commitment (Franko, 1989). Therefore, innovation may result in (more) international involvement.

Most previous studies only focus on the link between innovation and export. A number of empirical studies suggest that innovativeness of enterprises is likely to affect

the probability or propensity of enterprises to export, for example because innovation may improve the international competitiveness of an enterprise ((see e.g. Wakelin, 1998; Sterlacchini, 1999; Roper and Love, 2001; Karagozoglu and Lindell, 1998). For example Karagozoglu and Lindell (1998) argue, in their study on small and medium-sized technology based firms, that innovative enterprises are more likely to export, because prospects in international markets are more promising as compared to prospects in national markets.

Innovation, however, may not only stimulate enterprises to export but may also have an effect on the propensity of enterprises to import goods or services from abroad. In order to realize the necessary product and/or process innovation enterprises may need to import foreign inputs. Indications can be found that a positive relationship exists between innovativeness and the likelihood of enterprises to be involved in importing activities. For example, one study has shown that innovative SMEs are above average importing innovative (new) products (Van de Graaff and Overweel, 2002). However, there is a lack of empirical studies that address the link between innovation and import. In addition, no distinction is made between enterprises that are only involved in exporting activities and enterprises that are involved in importing as well as exporting activities. Since a positive relation between innovation and the propensity of enterprises to export and import is expected, it is likely that the relationship will be strongest for enterprises with exporting as well as importing activities as compared to enterprises that are only involved in one of these modes of internationalization. In the research design, therefore, the following hypotheses are formulated:

*Hypothesis 1: A firm's innovativeness is positively related to a firm's international involvement in terms of exporting goods or services.*

*Hypothesis 1A: A firm's innovativeness is relatively more positive related to enterprises that are both exporting and importing goods or services than to enterprises that are only exporting or only importing goods or services.*

## **DATA**

### **Sample**

The analysis is based on a representative sample of 1,846 Dutch SMEs (up to 100 occupied persons). The business owners were interviewed during July 2004. This resulted in detailed information on the international activities and innovativeness of Dutch SMEs.

### **Measures**

In the panel data were available for internationalization activities and innovation efforts at the firm level.

#### *Internationalization activities*

Several measures of internationalization activities are used in this paper. The measures were identified by asking the entrepreneurs whether they are currently undertaking exporting and or importing activities. Enterprises were categorized into the following categories:

- (1) **International involvement**; This variable takes the value 1 for enterprises that are exporting and/or importing goods or services and 0 for enterprises that are not involved in these modes of internationalization.
- (2) **Exports (and no imports)**; This variable gets the value 1 for enterprises that are only involved in exporting activities and that do not import goods or services from abroad, and the value 0 for all other enterprises.
- (3) **Exports and imports**; This variable is coded 1 for enterprises that are involved in exporting as well as importing activities and otherwise coded 0.
- (4) **Imports (and no exports)**; This variable takes the value 1 for enterprises that are involved in importing activities without undertaking exports, and 0 for all other enterprises.

### *Innovativeness*

Innovativeness was measured by several dichotomous (0/1) variables developed specifically for measuring innovativeness of SMEs. The following measures for the realization of innovations were used:

- **Recent product introductions (new to the firm)**. This variable is a proxy for product innovation or the renewal of products and/or services that a firm offers. The variable is coded 1 when the firm introduced at least one product new to the firm ‘during the last 3 years’; otherwise coded 0.
- **Recent changes or innovations in internal business processes**. This variable is a proxy for process innovation or the renewal or improvement of the working methods that are used. The variable is coded 1 when the firm has introduced changes or innovations in internal business processes ‘during the last three years’, and coded 0 otherwise.

Also, a number of measures for innovative practices were included in the analysis:

- **Strategic attention for innovation**. When the firm is continuously seeking for and providing support to innovative opportunities this variable is coded 1 and coded 0 in all other cases.
- **Use of external networks**. This variable is coded 1 for enterprises that keep up regular contacts with an external network of universities, suppliers and/or knowledge institutes to extent its knowledge base and is coded 0 otherwise.
- **Inter-firm co-operation**. When the firm formally co-operated with other firms or institutes to initiate or develop any renewal activities (evidenced by a formal agreement) this variable is coded 1 and otherwise it is coded 0.

### *Control variables*

The following control variables were used:

- **Sector of industry**: The firms were assigned to one of the following five industries: (1) manufacturing, (2) trade, (3) transport, (4) business services, and (5) other industries. ‘Other industries’ was used as a base case in the regression analysis (and was therefore not included in the regression equation). So four industry dummies were used to represent the industries.
- **Firm size**: Two size classes were distinguished for the SMEs in our sample: (1) 0-9 occupied persons, (2) 10-99 occupied persons.
- **Gender**: This variable takes the value 0 for females and the value 1 for males.

## EMPIRICAL ANALYSIS

The bivariate correlation coefficients between the variables for internationalization and current innovativeness are presented in Table 1. For enterprises with international involvement a significant positive correlation is found with all indicators of innovation. Recent product introductions ( $r= 0.237$ ;  $p \leq 0.01$ ) and recent changes or innovations in internal business practices ( $r= 0.130$ ;  $p \leq 0.01$ ) are positively related to enterprises that export and/or import goods or services from abroad. Also the innovative practices ‘strategic attention for innovation’ ( $r=0.169$ ;  $p \leq 0.01$ ), ‘use of external networks’ ( $r=0.109$ ;  $p \leq 0.05$ ) and ‘inter-firm co-operation’ ( $r=0.165$ ;  $p \leq 0.01$ ) show a significant positive correlation with international involvement. The variables firm size ( $r=0.101$ ;  $p \leq 0.01$ ) and gender ( $r=0.118$ ;  $p \leq 0.01$ ) also show a significant positive bivariate correlation with international involvement. Next, a significant positive effect exists for trade. On the other hand a significant negative correlation is found for business services and other industries.

Furthermore a significant positive correlation is found between ‘recent introductions of new products’ and enterprises with only exports (and no imports) ( $r= 0.116$ ;  $p \leq 0.01$ ). The variables ‘strategic attention for innovation’ ( $r= 0.106$ ;  $p \leq 0.01$ ), ‘use of external networks’ ( $r=0.059$ ;  $p \leq 0.05$ ) and ‘inter-firm co-operation’ ( $r=0.084$ ;  $p \leq 0.01$ ) also have a significant positive correlation with enterprises that are only involved in exporting activities (and that do not import goods or services from abroad).

For enterprises that both export and import a significant positive correlation can be identified between all indicators for innovation. First, a significant positive correlation is found with the variables for recent product innovations ( $r=0.256$ ;  $p \leq 0.01$ ) and recent process innovations ( $r=0.131$ ;  $p \leq 0.01$ ). The indicators for innovative practices ‘strategic attention for innovation’ ( $r=0.177$ ;  $p \leq 0.01$ ), ‘use of external networks’ ( $r=0.107$ ;  $p \leq 0.05$ ) and ‘inter-firm co-operation’ ( $r=0.195$ ;  $p \leq 0.01$ ) also show a significant positive bivariate correlation with international involvement.

For enterprises that only import goods or services from abroad (and that have no export activities) a significant positive correlation exists with the variable ‘recent changes or innovations in internal business processes’.

(INSERT TABLE 1 ABOUT HERE)

Table 2 shows percentages for each of the indicators for realization of innovation and for innovative practices across the categories for internationalization in the sample.

(INSERT TABLE 2 ABOUT HERE)

To confirm the identified relations of the correlation analysis we have to take account of other factors that may influence the propensity of enterprises to undertake international trading activities. To this end a regression analysis is carried out. International involvement is taken as the dependent variable. In order to investigate whether estimation results become different also alternative measures for internationalization are used as dependent variables. Considering the nature of the dependent variables binary logistic

regression analysis is used. Table 3 shows the results of the logistic regression analysis. The first column for each of the dependent variables pertains to the analysis where only the control variables were included in the model, whereas the second column for each of the dependent variable includes both the control as well as the predictor variables. From the model that only includes the control variables it is found that larger enterprises are more likely to undertake international trading activities than smaller ones ( $p \leq 0.01$ ). Also it can be seen that males show higher international involvement than females ( $p \leq 0.01$ ). Further, for all industry categories a positive impact is found on international involvement.

(INSERT TABLE 3 ABOUT HERE)

The following picture emerges from the analysis when the predictor variables for innovativeness are included. First of all recent product introductions have a significant positive effect on enterprises with international involvement. The effect is strongest for enterprises with both export and import activities, but also a significant effect for enterprises that only export can be identified, whereas no significant impact is found for enterprises with only import activities.

Second, the variable for recent process innovations ('recent changes or innovations in internal business processes') has a significant influence on international involvement. Interestingly a significant positive effect exists for enterprises that only import, while the effect is significant negative for enterprises that only export. No significant effect is found for enterprises with both exports and imports.

Furthermore, the variable 'strategic attention for innovation' has a significant positive impact on international involvement. A stronger significant positive effect is found for enterprises that only export than for enterprises with both exports and imports. No significant effect exists for enterprises that only import.

It can also be seen that inter-firm co-operation has a significant positive influence on international involvement. Looking at the other specifications of internationalized enterprises there is only a significant positive effect for enterprises with both exports and imports. Next, the indicator for innovativeness 'use of external networks' has no significant impact on the various measures for international business activities.

Based on the above support is found for hypothesis 1 stating that innovation is positively related to international involvement. Also some support is found for hypothesis 1A as the indicators 'recent product introductions' and 'inter-firm co-operation' have the strongest impact on enterprises that are involved in both exports and imports as compared to other categories of internationalized enterprises.

## **CONCLUSION AND DISCUSSION**

In this study we explored the relationship between innovation and international involvement. It was examined whether innovativeness (the realization of innovations and innovative practices) has an impact on (various measures of) international involvement. International involvement was defined as the extent to which enterprises are importing and/or exporting goods or services. While existing literature on internationalization of enterprises is strongly focused on export and other outward modes of internationalization, we also included inward modes of internationalization (imports) in our analysis. Also,

literature on the relationship between innovation and internationalization has thus far mainly focused on export.

From the results of the analysis it is found that innovation has a significant positive effect on international involvement. More specifically, the results suggest that SMEs that recently realized innovations (in products and/or internal business processes) are more likely to be involved in international trading activities than other SMEs. The effect of recent product innovations is strongest for enterprises with both import and export activities, but also a significant positive effect is found for enterprises with only exports. The effect of recent process innovations is significant positive for enterprises with only imports (and no exports). Remarkably, a significant negative effect was found for enterprises that only export (and do no import goods or services from abroad).

One explanation for the positive effect of recent process innovations on SMEs that only import may be that enterprises that realize process innovations may have a strong focus on internal matters of the firm. Process innovations are often initiated in order to realize cost reductions. One of the most important reasons for SMEs to import is to get access to know how and technology and to buy products at lower prices than would be possible on the national market (Hessels *et al.*, 2005). Thus, imports may provide firms with access to the necessary know how/technology or to (cheap) inputs needed for realizing the required innovations in business processes. A focus on internal processes and cost reduction may also imply that enterprises are not so much concentrating on seeking foreign market expansion, which may explain the negative effect on enterprises that only export. Process innovations, however, may result in product innovations. In accordance with previous studies it is found that product innovations may stimulate enterprises to start exporting. But the results of this study further indicate that product innovations have the strongest impact on enterprises that both export and import, which suggests that enterprises that recently introduced renewals in the products or services they offer are likely to have an outward as well as an inward oriented international focus.

Furthermore, it also found that most of the innovative practices used in the analysis have a positive impact on the likelihood of enterprises to be involved in international markets. Enterprises with strategic attention for innovation and enterprises that are formally co-operating with other firms or institutes to initiate or develop any renewal activities are more likely to be involved in international trading activities than other enterprises. Strategic attention for innovation has a significant positive impact on enterprises with both exports and imports, but the positive effect is strongest on enterprises that only export. Thus, strategic attention for innovation seems to be mainly related to an outward oriented international focus. In general it requires more effort for a firm to export than to import, which is for example illustrated by the fact that enterprises barely face barriers in the import process (Hessels *et al.*, 2005). In order to export their products or services enterprises normally need to develop an export plan and export strategy. It is possible that enterprises with strategic attention for innovation are more ready or capable to devoting strategic attention to and preparing themselves for the export process.

In addition, the results of this study reveal that inter-firm co-operation has a significant positive impact on enterprises with both exports and imports and no significant impact on enterprises that are involved in only one of the modes of internationalization. Finally, the results of the analysis suggest that keeping up regular

contacts with external networks of universities, suppliers and/or knowledge institutes does not have a significant effect on international involvement of SMEs.

Based on the analysis it may be concluded that it is useful to include imports in the analysis when studying the relationship between innovation and internationalization. Furthermore, the results indicate that it may be valuable to make a distinction between enterprises that are solely involved in import or export activities and enterprises with both imports and exports.

More research is needed in order to better understand the complex relationship between inward and outward modes of internationalization and to assess the relationship of these international business activities with innovation. Using an analysis over a longer period of time would provide better insight into the relation between innovation and internationalization behaviour of firms. In the analysis presented above only two modes of internationalization (import and export) are included in the analysis. Future research could also take account of other modes of internationalization such as foreign direct investments and international co-operation.

## **Frontline HR Involvement and Satisfaction in Small and Emerging Firms: An Exploratory Analysis**

Many times employees in small and emerging firms make the difference between success and failure. In many cases, the owner or manager of a small emerging business handles the human resource functions alone since he or she is usually limited when the firm employs only a few people. Also, even as the firm grows, it may not have the resources to hire a human resource specialist. This practice of informal human resource management may be detrimental to a firm's success. Each year there are a large number of failures in smaller firms in different geographic locations and in different industries. In many cases, the owners report managerial incompetence as the major underlying reason (Dun & Bradstreet, 2001). One specific area of managerial incompetence continually cited is dealing with employee problems that includes recruiting, selection, ineffective or nonexistent training, compensation and benefits, and weak or nonexistent performance appraisal.

There has been a large amount of recent literature devoted to human resource management for larger firms. HRM issues that have been researched include the importance of human capital (Stewart, 1992); the impact on performance and turnover (Arthur, 1994); the impact on financial performance (Huselid, 1995); the impact on organizational performance (Delaney and Huselid, 1996; Huselid, Jackson, and Schuler, 1997); and HRM's effect on competitive advantage (Lado & Wilson, 1994; Barney, 1991; and Kamoche, 1996). An examination of the progress of human resource management's impact on firm's performance as well as its prospects for the future (Becker & Gerhart, 1996) has caused researchers to examine the relationships and configurations within organizations that lead to effective human resource architecture (Lepak & Snell, 1999). On the other hand, research concerning HR practices in

small and emerging organizations is more embryonic. While these businesses make up the majority of firms in the U.S., much less research exists to help us understand the dynamics of effective HR functions in these firms.

### **Recent Literature on the Role HR in Emerging Firms**

In the midst of the recent increase in HRM research, there is still a lack of concentration or applicability to smaller ventures. It should not be assumed that the research results demonstrated from larger firms automatically apply to smaller ventures. In fact, specific research on the HRM practices of smaller ventures has been called for (Purcell, 1993) in order to better assess the needs, concerns, challenges and strategies that will enhance their growth and performance. Marlow & Patton (1993) argued that the effective management of human resources is emerging as a key to survival for smaller ventures.

The practice of effective human resource management is one that has been shown to be an integral part of the success of smaller businesses (Hornsby and Kuratko, 1990; Smith, 1991; Deshpande and Golhar, 1994; Jones, Morris, and Rockmore, 1995; and Wager, 1998). The vast majority of businesses in the U.S. today employ fewer than 100 people (U.S. Small Business Administration, 2000) yet, as illustrated earlier, most research conducted in the HRM field tends to focus on larger firms that employ full-time HRM professionals.

One early study of HRM functions in smaller ventures found that areas of accounting, finance, production, and marketing, all take precedence over human resource management (McEvoy, 1984). In many cases, the owner of a small emerging business handles the human resource functions alone since he or she is usually limited when the firm employs only a few people. This practice of informal human resource management may be detrimental to a firm's success. Each year there are a large number of failures in smaller firms (across different geographic locations and in different industries). Owners report managerial incompetence as the major underlying reason for these failures (Dun & Bradstreet, 2000). One specific area of managerial incompetence continually cited is dealing with employee problems which includes

recruiting, selection, ineffective or nonexistent training, lack of benefits, lack of incentives, inequitable compensation and weak or nonexistent performance appraisal.

A survey conducted by Hess (1987) showed that owners of smaller ventures rank HRM practices as the second most important management activity next to general management work. Amba-Rao and Pendse (1985) surveyed the compensation and maintenance practices of 78 small firms. Their study found that most firms lacked any systematic or rational approach in their compensation practices. Little (1986) examined the HRM functions in 275 small firms employing fewer than 100 employees. This study found that typically the owner of a firm with less than 50 employees handled the HRM function, while 62 percent of the firms with 51 to 100 employees had a full-time human resource manager.

Only a handful of HRM studies on U.S. small ventures were conducted in the 1990s. The empirical research seemed to suggest that smaller firms were progressing in developing HRM practices and policies. Hornsby and Kuratko (1990) studied 247 smaller ventures and found that firms under 50 employees had very little in place regarding formal HRM practices; however, firms with 50 to 100 and 101 to 150 employees had similar HRM practices in place. These firms cited the availability of a quality labor pool as the most critical HRM issue. Another basic finding was that company size did significantly affect the use of formalized HRM practices, especially for job analysis, recruitment, compensation, benefits and incentive plans. However, less than half the firms surveyed employed any formal HRM practices.

In a study of Canadian businesses, Ng and Maki (1993) found a significant difference between large and small firms in their ranking of the importance of HRM functions. Smaller firms rated the retaining, obtaining and identifying functions as most important while large firms rated adjustment, identifying and developing employees as most important. In another Canadian study, Deshpande and Golhar (1994) found that workforce characteristics including firm success, ability to inspect work, worker flexibility, ability to work in groups, and self-discipline were perceived to be more significant to smaller firms. Duberley and Walley (1995) concluded from a

study of sixteen manufacturing firms that there existed a wide variety of practices among firms yet few had developed an integrated set of strategic HRM practices.

Wager (1998) studied the determinants of HRM functions in small Canadian firms and found that less than half of the companies surveyed utilized formal appraisal (50 percent), sexual harassment policies (35 percent), employee pensions (30 percent), TQM (34 percent), employee assistance programs (21 percent), employee attitude surveys (27percent), and employee relations (19 percent). The research also showed that firms which emphasized open communication and employee participation were much more likely to have formal HRM procedures.

The studies cited above found consistent results regarding the limited use of HRM functions in smaller firms. However, after the Hornsby and Kuratko (1990) study, most of the research that investigated the extent of usage of formal HRM activities was conducted outside the U.S. The goal of this study was to investigate the current state of human resource management practices in U.S. smaller ventures as well as the critical HRM issues of small business owners, and compare to the findings in a study ten years ago (Hornsby and Kuratko, 1990).

### **Frontline HR Management**

Since many small and emerging companies do not have a designated human resource person, the responsibility of identifying and developing key personnel often is bestowed on the line managers. In fact, managers actually implement most functions while human resource representatives administer and coordinate these activities. Specifically, managers are usually responsible for interviewing, training, appraising and disciplining their subordinates. In addition, managers play important roles in compensation, safety, job analysis and planning. Therefore, managers will serve as the first-line human resource manager for your company. This is especially the case in smaller firms and growing firms where the existence of a human resource department is less likely. Approximately 99.7 percent of all businesses in the United States have

less than 500 employees and 78.8 percent have less than 10 employees (U. S. Small Business Administration Office of Advocacy (1997)).

While smaller firms espouse to grow into larger firms, focus is needed to provide guidance on effectively dealing with human resource issues as they emerge from a fledgling company to one that must deal the challenges presented by larger employee groups. In support of this argument, a study of young entrepreneurs found that HR topics ranked highest among areas for needed learning (Heneman, Tansky, and Camp, 2000). The purpose of this paper is to examine the use and satisfaction of human resource practices by frontline managers in emerging firms. Specifically, this study examines the extent to which these managers practice effective HR, their satisfaction with these activities, and the amount of training their firms provided.

## **Method**

### **Sample**

Three hundred emerging companies located in the Midwest United States were sent a survey concerning their company's practices regarding frontline HR management. Student research assistants were utilized for survey distribution and data collection. Using surveying methodology similar to McEvoy (1984) and Hornsby and Kuratko (1990), research assistants utilized Chamber of Commerce directories to develop a survey list. These directories were the same data source used in the Hornsby and Kuratko (1990) study. Probable respondents were contacted and asked to participate. Surveys were then distributed and collected by the research assistants. The respondents were further divided into three size categories based on the theory that, in general, a company's human resource practices will become more sophisticated as employment size increases. Specifically, three size categories were utilized. The first category included "smaller" firms with companies having 100 and under employees. The second category consisted of "medium-sized" small firms and included companies that employed between 101

and 500 employees. Finally, the third category consisted of “larger” small firms and included companies that employed between 501 and 1000 employees.

### **Instrumentation**

The data were gathered by means of the 15-item questionnaire. The survey investigated each company’s demographic background (i.e., type of business, size, and revenues) and frontline HRM practices in seven major areas (hiring/selection, HR planning, performance appraisal, training/coaching, wage administration, safety administration, and discipline/employee relations). The respondents were asked to rate, using a five-point Likert scale, their frontline manager’s involvement with these functions and the extent to which these frontline managers are held accountable for these HR responsibilities. In addition, respondents were asked whether or not training is offered to frontline managers and the extent to which the training is offered. Finally, respondents were given a chance to list the most significant challenges facing managers and supervisors.

### **Results**

A total of 110 surveys were returned representing a 36.7 percent response rate. Tables 1 and 2 provide a descriptive summary of the results. Some overall results worth noting are described below.

- On a scale of 1 to 5 with 5 indicating very important, respondents rated the importance of HR activities at 4.7 average.
- On a scale of 1 to 5 with 5 indicating very involved respondents rated overall managerial/supervisory involvement at 3.78. When broken down by HR function the average involvement was rated at 4.43, 2.77, 4.52, 3.69, 3.15, 3.63, and 4.28 for hiring, planning, appraisal, training, wages, safety, and discipline respectively. Further analysis found that overall, firms with 50 to 100 employees have managers most involved in HR practices and firms 101 to 200 have managers least involved.

- On a scale of 1 to 5 with 5 representing most satisfied, respondents were most satisfied with the hiring activities of their frontline managers (mean=3.95) and least satisfied with the planning activities conducted (mean=3.22). Smaller firms with less than 200 employees were more satisfied with the HR practices of their managers.
- Fifty-nine percent of the respondents indicated that they offered some sort of formal training for their managers in the form of in-house seminars, college courses and online programs. Most the training was in the areas of discipline and appraisal.
- The top five challenges facing frontline managers, as cited by the respondents, include keeping up with laws and regulations, employee relations/discipline, consistency and fairness, finding quality employees, and training.

A further breakdown by size category as presented in Table 1. Some interesting size differentials are noted below.

- Firms over 100 employees are twice as likely to have an HR professional.
- The importance of frontline manager responsibilities for administrative HR such as compensation and planning decline as the size category gets larger.
- There appears to be little difference across size categories for the importance of the supervisor's role in the following: performance appraisal, training, safety, and discipline. Also, in all cases, the average rating of importance was above 4.0 signifying the critical role played by the frontline manager in these functions.
- As the size categories increase, satisfaction with how all seven HR functions studied are performed seems to decline.

- Findings for the percentage of firms holding frontline managers accountable for each HR function parallel the findings cited earlier regarding the importance of the supervisor's role in each of the seven HR areas studied.
- Firms larger than 101 employees seem to offer more training, especially in performance appraisal, training, safety, hiring, and discipline. Most of the training seems to be in the areas of performance appraisal and discipline.

### ***Discussion***

The implications of this study are that firms entrust their managers with a high level of employee responsibility but do not provide sufficient training and preparation for these managers to be successful (especially in smaller firms). As firms continue to outsource HR management or downsize HR managers, the role of the line manager in conducting HR practices will continue to grow. This gap in practice and training should be narrowed.

## **Abstract**

In the new economic era that features speedy advancement in technology, entrepreneurship has become one important element of economic development. Although recent empirical studies based on data collected mainly in the mature economies have, to some extent, shed light on the interactive roles of entrepreneurship and economic development, they have so far failed to demonstrate detailed chronicle evidences. Furthermore, little evidence has thus far been presented based on experience drawn from newly industrialized economies. Taiwan has long been famous for its abundant entrepreneurial resources and speedy development. This study focusing on Taiwan, has compiled data covering various stages of economic development to clarify the relationship between entrepreneurship and economic development. We use both the rates of self-employment and the shares of SMEs as main indicators of entrepreneurship in this study. The empirical evidence shows the systematic relationship that exists between entrepreneurship and economic growth, with both the time trend of rates of self-employment and that of the SME sector coming hand in hand as the economy developed. We have further demonstrated that as Taiwan reached the more matured stage of development, the rates of self-employment catch the essence of entrepreneurship better than the importance of SMEs. We then show that as the supply of Schumpeterian entrepreneurs in the island is amounting, the rates of self-employment continue to increase, and then we see the subsequent growth of the economy. This study also demonstrates empirically the existence of the hypothesized U shaped trend of entrepreneurship that based on deductions from the experience of industrialized countries realized in Taiwan.

## **Introduction**

In the new economic era that features speedy advancement in technology, entrepreneurship has become one important element of economic development. In the new century, the comparative

advantage of an economy lies in the abundance as well as quality of entrepreneurs in stead of traditional inputs such as labor and capital. Entrepreneurship, though an old concept, has now become an important research topic in the new settings. Many studies launch to decide empirically the relationship between entrepreneurial activity and economic development. These studies have, to some extent, shed light on the interactive roles of entrepreneurship and economic development, with some empirical studies based on evidences drawn from recent experience in well-developed economies, showing that there exists a positive relationship between entrepreneurship and the growth rate of an economy. However, none of these works is based on less-developed sample, and most of them consider only cross sectional data. In order to enrich our understanding of the relationship between entrepreneurship and macroeconomic development, there is a need for an enhanced empirical study aimed at highlighting long-term observation of a fast growing economy, such as Taiwan.

Taiwan, who is famous for her speedy economic development, has been described as a boss's island for its flourishing entrepreneurial resources. Taiwan's SME sector is considered to be a major contributor of the island's economic growth. Even though SME sector can be seen as a vehicle for entrepreneurship, little evidence so far demonstrates directly the linkage between entrepreneurship and Taiwan's economic development. The main purpose of this study is to clarify the relationship between entrepreneurship and economic development with Taiwan, a catching-up economy, as a case study. We will use census data published from 1960s to 2000s to decide the pattern of the long run evolution of Taiwan's entrepreneurial resources as the economy progresses.

The paper is structured as follows. We begin by carrying out a literature review in the next section, followed in the subsequent section by observing the long-term evolution of relevant census data from Taiwan, and examining the hypothesis regarding economic development and entrepreneurial activity. We close by a summary of our findings.

## **Literature Review**

Since SMEs have often been considered to be an indication of entrepreneurship, many works circle around the issue of the relationship between SMEs and economic growth in the late 1990s. Thurik (1996) empirically applies data from twelve European Union member countries to examine whether the growth of small firms has any significantly higher impact on GNP growth than the growth of large firms, and concluded that smaller, and thereby, more flexible, firms are the answer to Europe's problems of unemployment and weak competitiveness. Furthermore, base

on the evidence from thirteen European countries, Carree and Thurik (1998) indicate that in 1990, the increase in the employment share of large firms has a negative effect on output growth. Apart from these works used mainly European cross country data, Acs, *et al.* (1999) base on manufacturing data within US from the early 1990s, and find a negative impact on productivity dynamics from the shares of small businesses. Also in a regional setting, Shaffer (2002) tests the Schumpeterian hypothesis, and suggests small manufacturers and retailers are positively associated with economic growth rates in the US. Based on data covering thirty-seven countries, over the period from the 1960s to the 1990s, Hu and Liu (2003) support empirically the hypothesis that small businesses are beneficial to economic prosperity. Hu and Liu (2003) also draw conclusion that in the pursuit of economic growth, SMEs in the high-income economies will generally exploit entrepreneurship, whilst in the less-developed economies they will tend to drive the job-creation function.

More recently, we find many works address directly the issue of the impact of entrepreneurship. There are studies attempt to test empirically the indication of entrepreneurial activity that lead to economic development. Among them, many use regional data within a country. Audretsch and Fritsch (2003) use regional data from West Germany to link entrepreneurship to growth, and find only the growth in the 1990s were relating to entrepreneurial activity in the 1980s. In another article, Audretsch and Keilbach (2004: 419) also find in Germany, there is a positive linkage between entrepreneurship capital and regional economic performance. Other recent empirical works with regional data suggest similar results. For example, Braunerhjelm and Borgman (2004) with Swedish data, and Berkowitz and DeJong (2005) with Russian data both illustrate the regional entrepreneurial activity is relating to subsequent regional growth.

Two studies consider cross-nation evidences. Salgado-Banda (2002) uses data of 22 OECD countries from 1978 to 1998 and finds different measures of entrepreneurship entail different results on economic growth. Innovation has positive impact on growth, while self-employment reduces growth. Tang and Koveos (2004) test the hypothesis with cross-country data, their results are also mixed. They conclude that the relationship between entrepreneurship and economic growth largely depends on the measures of entrepreneurship as well as the country group with differential income level.

Even though this line of research does draw a lot of attentions, and it does provide many empirical evidences, there is limitation. For example, not much recent cross- nation studies are made. The implications deduced from researches with cross- sectional regional data to test the relationship between growth and entrepreneurship are not quite the same as those from cross

national data. Those works based on nation wise data have tended to draw mainly on the experiences of the industrialized countries.

Further, none of these empirical studies is based on long-run time-series data. With the only exception when Baumol (2004) discusses entrepreneurial enterprises as one of the free-market growth machine. In his attempt to provide indicators, Baumol (2004: 17 and 18) uses long-term growth trend of British per capita GNP and the increasing trend of US private R&D expenditure for last five decades to demonstrate the exploding of both income and R&D activity.

Why only a handful of empirical study draws from long-run observations? The answer lies mainly in the lack of proper sample. While the subject about economic development and entrepreneurship needs to be supported by successful demonstration with some long-term, single-economy observations. Wennekers and Thurik (1999) provide a detailed survey of the literature surrounding entrepreneurship and economic growth. The authors also use historical case studies with East Asian miracle as empirical evidences of the positive relationship between entrepreneurship and economic development. Taiwan is considered to be one of the high-performing Asian economies in their study, and a successful example of an economy with long-term growth (Wennekers and Thurik, 1999: 39).

Now that the focus is on long-term growth of a nation, the angle must shifts from cross sectional observation to time series consideration. When consider the feedbacks from economic development to entrepreneurial activity, Wennekers and Thurik (1999: 48, 49) illustrate a tentative U-shaped trend of self-employment rates over time. As the stage of economic development proceeds, increased income will first decrease self-employment rate, then, as economy matured, the number of Schumpeterians and intrapreneurs will increase. So far, there is no empirical study addresses directly the hypothesis concerning the long-term trend of entrepreneurial activity; we therefore see a need to generalize our empirical study of these issues by taking into account a complete development process of a real economy.

### **Entrepreneurial Activity and Taiwan's Economic Development**

As one of the most dynamic economies in the world, Taiwan is often considered to have the most flourishing entrepreneurial activity. For example, it is well documented that in Taiwan, SMEs involved directly or indirectly in the production process, combining with their larger counterparts to supply output to the markets, form a healthy industrial structure that is beneficial to economic development (Schive and Hu, 2001: 254). Table 1 reports the time trends of data representing

economic development (per capita GNP), and entrepreneurial activity using Taiwan's census data prepared between 1961 and 2001. Three indicators of entrepreneurial activity are used: SME shares in number of firms, employment share of SMEs, and the self-employment rate, which is defined as the ratio of the number of entrepreneur (firm owner or self-employed person) to work force in Taiwan private sector. SMEs are defined here as firms with less than 100 employees.

---

Table 1 here

---

SMEs have accounted for a large share of total number of companies in almost all economies. In Taiwan, the situation is even more obvious. For example, in 1961, 99.57 percent of private enterprise in Taiwan was SME. This ratio slipped slightly to 98.9 percent in 1976, and then followed by a rising trend (see Table 1). It is evident from these figures how Taiwan earns the reputation of being an island of boss. As another indicator of entrepreneurship, the employment shares of SMEs first decreased then increased. The increasing trend started from 1971, when employment share of SMEs was 52.52 percent, which rose to 57.89 percent in 1986. Then, from 1986 to 1996, the share rose to a new peak of 66.75 percent, an increase of nearly 9% over the ten-year period.

Although the importance of SMEs experienced a recent decrease, they still accounted for more than 60 percent of total employment, and 52 percent through out the sample period. Finally, the last indicator of entrepreneurship in Table 1, the number of firm owner as a share of total work force first decreased from 14.33 percent in 1961 to 10.22 percent in 1976, then increased to 12.15 percent in 2001. These records were documented as the economy progressed. Back in 1961, the per capita GNP of Taiwan was only 154 (USD). Back then, Taiwan was a low income country according to the World Bank categorization. In 1976, Taiwan was already a middle income nation, with a 1,132 (USD) per capita GNP. After 1991, Taiwan proudly graduated into the high income class.

Figure 1 highlights the U shaped, reversing trend of the rates of self-employment. It is also interested to note that the turning point of the trend of the self-employment rates was witnessed in 1976, the same time when the share of SMEs as the number of company rocked bottom. Figure 1 also shows the reversing trend of the employment share of SMEs, and the recent down turn in Taiwan. The trend of the employment share of SMEs first reversed in 1971, a little earlier than that of self-employment rates and number share of SMEs. The second time when the trend of the employment share of SMEs reversed was recorded in 2001, about the same time the economy was

experiencing first and only business downturn during the sample period.

---

Figure 1 here

---

Today, per capita GNP in Taiwan has reached a record high of 14,032 (USD). Since the most recent statistics reveal that Taiwan has finally regain vitality, while the rates of self-employment have been growing since 1970s, there must be some connection between Taiwan's entrepreneurship and economic development. This result also echoes that of Audretsch and Fritsch (2003). In the discussion of the development and contribution of Taiwan's SMEs, Hu (2003) has contributed the abundance and quality of the pool of entrepreneurship as an important facilitating factor to the nation's economy. Entrepreneurs in Taiwan not only provide competitive edge to enhance free- market growth machine. They are also important job providers. The strong entrepreneurship in Taiwan also stimulates a high rate of technology diffusion (Hu and Schive, 1998). By playing various roles, Taiwanese entrepreneurs have helped directly and indirectly the speedy development of the economy.

Will these heroic entrepreneurs maintain their importance when facing the new challenge in the know-based environment? Will there be enough Schumpeterian entrepreneurs sprout in the economy? Both answers are positive for Taiwan. When looks at the market entry of Taiwan manufacturers, Hu (2004) discovers that the electrical and electronic machinery industry has the highest entry rate among all other 2 – digit manufacturing industries. From 1993 to 1997, the average annual entry rate for electrical and electronic machinery industry in Taiwan is 18.2 percent. Which means a majority of contenders in the market is from the high-tech sector. Since the electrical and electronic machinery industry is considered to be an important sector for innovation, these new comers must fit in the Schumpeterian profile.

### **Concluding Remarks**

Taiwan has long been famous for its abundant entrepreneurial resources. Although recent empirical studies based on data collected mainly in the mature economies have, to some extent, shed light on the interactive roles of entrepreneurship and economic development, they have so far failed to demonstrate detailed chronicle evidences. Furthermore, little evidence has thus far been presented based on empirical data on the newly industrialized, fast growing economies, such as Taiwan. In this study, we have compiled data covering the period from the 1960s to 2000s. These samples represent the status of Taiwan economy and entrepreneurship in various stages of

economic development. The empirical evidence shows the systematic relationship existing between entrepreneurship and economic growth, with both the time trends of the rates of self-employment and that of the SME sector coming hand in hand with economic development.

We have further demonstrated that as Taiwan has become a member of high income nations, the rates of self-employment catch the essence of entrepreneurship better than the importance of SMEs. Both trends now evolve differently. After the long term prosperity over the last five decades, Taiwan economy experienced business downturn in the turn of the century. Giving the fact that the supply of Schumpeterian entrepreneurs is amounting, the rates of self-employment still increase, we see the subsequent growth of the economy after previous set back.

Finally, it is demonstrated in our study, a real life example of the long term relationship between entrepreneurship and economic development depicted by Wennekers and Thurik (1999). Who hypothesized a U shaped trend of entrepreneurship as the economy developed, based on deductions from the experience of industrialized countries. This result not only shows Taiwan's economy has leaned closer toward other more developed counterparts. It also demonstrates the quality of Taiwanese entrepreneurs is fact first class in the world.

Given the limited number of observations, more sophisticated, influential statistical methods are precluded from our study. No definitive conclusions on the relationship between macroeconomic development and entrepreneurial activity can be drawn from these statistics. However, there is sufficient evidence to suggest that Taiwanese entrepreneurs are the 'jewel in the crown' of the island's economy.

**ABSTRACT**

Electronic Mentoring or E-Mentoring as it is more commonly termed, although becoming established in some fields, is still relatively new in the area of supporting the development of entrepreneurs; the Small Business Service<sup>1</sup> (SBS) and South East England Development Agency<sup>2</sup> (SEEDA) were the first to test this innovative approach with entrepreneurs. Combining the core principles of mentoring with today's technology enabled E-Mentoring to offer a more cost effective approach for funded business support increasing the availability of mentoring.

This paper seeks to provide a critical review of MentorsByNet, the E-Mentoring programme offered for the development of entrepreneurs by entrepreneurs in the UK. MentorsByNet has now attracted over 500 participants and created over 200 E-Mentoring relationships since its re-launch, following the initial pilot, in October 2003. The pilot programme was originally independently evaluated by Prof David Megginson, (Megginson 2003), similar questions formed the basis for ongoing evaluations throughout the programme, and this paper will review the responses to evaluate the progress achieved.

**Key Words:** Mentoring; E-Mentoring; Business Mentoring; Entrepreneurs Development; Business Support; SME Support; SME Development

## INTRODUCTION

In January 2003 an E-Mentoring pilot project was established by the SBS South East England Regional Team to test the feasibility of providing business mentoring to entrepreneurs. This was to take the form of non face-to-face communications through electronic means within a structured and formal relationship. The pilot was commenced following extensive research of the subject during 2001/2, (Hunt 2001, Bianco 2002, Bianco & Bianco 2002 and Perren 2002), with funding support from both SBS and SEEDA. The initial pilot involved 40 matched mentees and mentors, was run over a three-month period, with an independent evaluation Megginson, Stokes & Garrett- Harris, (2003). The pilot programme was considered to be successful and the full programme was rolled out in October 2003, since then MentorsByNet established over 300 E-Mentoring relationships and has over 700 participants registered to its programme. This paper will go on to review the results from the ongoing evaluations and those from the pilot programme to understand the effectiveness of this approach for the development of Small & Medium Sized Enterprises (SMEs) entrepreneurs.

There appear to be a significant number of ‘experts’ that believe the only effective method of mentoring is the traditional basis of face-to-face and that the asynchronous and non physical nature of E-Mentoring, (Electronic Mentoring also known as Telementoring, Cyber-Mentoring, Internet Mentoring, etc.), cannot deliver the same level of benefits to the mentee. Whilst this paper will not draw a direct comparison between the two approaches the literature reviewed will draw on both domains for the effectiveness of the E-Mentoring relationship to be evaluated. Dr Bob Garvey, Hunt (2004b:5), introduces e-mentoring as a new and effective approach to mentoring:

## ICSB Conference – Washington – June 2005

*“E-mentoring is a recent development in the field of mentoring and one which is already showing significant advantages over more traditional forms. E – Communication can be very liberating for both participants and some of the traditional difficulties in face to face mentoring, such as power differences, gender and race issues are simply not present in a virtual environment. It is also clear that the strong benefits of mentoring are present in an e-format. The time factor in e-mentoring can also play an important developmental role, allowing both real time fast communication and time lags for reflection. Another great advantage of e-mentoring is geography is no barrier to participation!”*

For completeness this paper will endeavour to describe some of the key processes and approaches adopted by Circle Squared Europe Limited<sup>3</sup> in the development and ongoing delivery of the MentorsByNet programme. The approach adopted for the MentorsByNet programme was based on the 5Ms framework

### MENTORING

Nandram, (2003) feels that a common definition for mentoring is impossible, as the term has become diffused and used in a large number of different contexts where diverse meanings are applied. Ambrose & Pullin (2004) cites (Hunt & Michael 1983) saying that the word Mentor has its origins in Greek mythology, Odysseus entrusted the education of his son, Telemachus, to a trusted counsellor and friend. This trusted and wise friend, Mentor, reportedly became the counsellor, guide, tutor, coach, sponsor and mentor for his protégé, Telemachus. Indeed many of us can think of examples of where an individual has influenced us in a positive way at some point in our lives.

## ICSB Conference – Washington – June 2005

Although we continue to seek a more modern and unified meaning for mentoring, Clawson (1996), none have so far been agreed due to the many different applications in today's environment. Since the late 70's there has been considerable debate around the value of individuals in mentoring relationships where the focus of attention is placed on the quality of the mentoring relationship (Higgins & Kram: 2001). This is emphasised by Eby (1997) who often refers to mentoring as "an intense developmental relationship". Clawson (1996) maintains that mentoring is broader than coaching and results in a more in-depth relationship over a longer period.

Bennis (2004), while discussing his view of the seven stages of leadership, reiterates the importance of having a mentor at various stages of a leader's personal development, from the very first stage through to the mature stage when perhaps, the mentee becomes the mentor! Stokes (2003) discusses the strongly interpersonal relationship between mentee and mentor in which a safe place exists for the mentee to explore and grow. This is further supported by Alred & Garvey (2000:146):

*"A mentor is sensitive to the emotional and intellectual aspects of the mentee's world. Offering empathy is a basis for establishing trust in the mentoring relationship, a condition for learning that goes beyond the routine and the instrumental."*

Murray (1991) defines mentoring as '...the deliberate pairing of a more skilled or experienced person with a lesser skilled or experienced one, with the agreed-upon goal of having the lesser skilled person grow and develop specific competencies....' The mentor acts

## ICSB Conference – Washington – June 2005

as a confidante and, as Clutterbuck & Megginson (1998) put it; will offer 'help...in making significant transitions in knowledge, work or thinking'. Mentoring relationships can be highly structured or fluid in design allowing the relationship to move in any direction the mentor and mentee agree, but always in support of the mentee's goals. In recent times mentoring has been identified as an important learning activity in a variety of contexts (Hansford, Tennet & Ehrich: 2002), such as businesses and the more traditional learning environments.

As in all aspects of mentoring, more critical questions are now being asked about the quality and effectiveness of mentoring relationships Stokes, Garrett & Hunt (2003). Ragins, Cotton & Miller (2000) draw our attention to the dangers of so-called 'marginal mentors' and McAuley (2003) explores what he refers to as the 'ambivalence' of mentoring, employing psychoanalytic constructs such as transferences and counter transference between mentor and mentee.

In many traditional didactic cases where mentoring programs were reported to have negative outcomes, success appeared to have been jeopardised by lack of time, lack of training; the negative attitudes of others or poor matching of mentors and mentees (Hansford *et al.*:2002). We will explore how some of these problem areas can be alleviated through E-Mentoring.

### E-MENTORING

When the term "mentoring" is used, face-to-face mentoring generally comes to mind first for most people, although with the increased use of electronic communication, e-mentoring is becoming increasingly popular, Hunt (2004). Many of the goals and purposes of face-to-face

## ICSB Conference – Washington – June 2005

mentoring and e-mentoring are similar as in both forms of mentoring, a more experienced and knowledgeable person provides advice, support, and encouragement to a less experienced person.

With the growth in information technology, e-mentoring is now providing opportunities for mentoring not possible with some face-to-face mentoring programmes and it has only been in the last few years that electronic communications have reached the levels of reliability and capability for vibrant relationships to flourish. The convenience of this style of communication allows for, regular, informal discourse between individuals in disparate locations. It appears that one of the greatest advantages of e-mentoring is that it provides a very flexible communication environment independent of time and space, allowing for asynchronous exchanges, thus making them an ideal medium for mentoring

While there has been a veritable explosion of online mentoring websites and opportunities within a wide variety of professions, very few academic articles to date have addressed this phenomenon Ensher, Heun & Blanchard (2003). Stokes *et.al*, (2003) also identified that as yet, there is relatively little empirical evidence to constitute a thorough exploration of what e-mentoring is and whether it works or not.

Perren (2002), in a piece of research commissioned by the authors during the development phase of MentorsByNet programme, identified a limited number of published articles, supporting the view that few academics have sought to address this area of research to date. This looked primarily at the research of e-mentoring and its relevance to entrepreneurs.

To date any research on E-Mentoring immediately runs into a barrier over the definition: Kasprisin, Single, Single & Muller (2003) point out that, e-mentoring “...has also been

## ICSB Conference – Washington – June 2005

popularly termed telementoring, cyber mentoring and on-line mentoring...". Perren's (2002) review identifies use of the internet, using email and list servers and non face to face methods of interaction as being key aspects of e-mentoring. Although the literature in this area is relatively sparse, some definitions are offered for e-mentoring. For example, Single & Muller (2001) define e-mentoring as:

*"A relationship that is established between a more senior individual (mentor) and a lesser skilled or experienced individual (protégé), primarily using electronic communications, that is intended to develop and grow the skills, knowledge, confidence, and cultural understanding of the protégé to help him or her succeed, whilst also assisting in the development of the mentor".*

This is useful as a starting point but is, arguably, not hugely differentiated from many definitions of traditional mentoring: the same could be said of others offered in Perren's (2002) review. Gibb (1994) argued that mentoring cannot be explained through a single universal definition, an argument that can equally be applied to E-Mentoring.

After an extensive literature search Perren (2002) identified 20 papers that initially looked to be relevant to both E-Mentoring and Entrepreneurs, however further analyses reduced this to three core papers, a brief summary of each follows:

- Evans and Volery (2001) - this article looks at providing "business development services, such as training... and networking" through the internet by asking 'experts' "from around the world." Three success factors are found: 1. Internet communication is perceived as "second-best" to face-to-face; 2. So face-to-face contact is needed as a

## ICSB Conference – Washington – June 2005

primary form of communication, internet provision is not a substitute; 3. The management of the internet site and program is a key factor".

- Stokes (2001) - this article is one of the most focused on the topic of the review as it looked at the feasibility of introducing a UK on-line tele-mentoring advisory scheme based on the Distance Learning Advisory Service in the Netherlands. Focus Groups were used to ask owner-managers what they thought about the idea. Owner – managers saw computers as a vital part of their businesses, but there was a wide range of application of computers and levels of confidence varied. Issues of trust, flexibility of delivery of support and time were repeating themes. Owner-managers also thought that face-to-face tutorship and networking with peers was important and they liked the idea of directed tutorship/mentoring rather than just brainstorming.
  
- Sullivan and Duffy (2000) - this article builds on Sullivan (2000) and reports some of the same issues. This summary will concentrate on the additional features of the article that look specifically at e-mentoring. A range of e-tools are suggested that could support entrepreneurs and facilitate e-mentoring including: email, email with attachments, asynchronous electronic discussion forums (not in real time) and synchronous teleconferencing (in real time). Discussion forums could allow entrepreneurs to share and discuss concerns and mentors could make contributions. Teleconferences are normally arranged at a pre-arranged time, it is suggested that the "role of the mentor is to assist focusing the group on a topic of discussion and ensuring that all participants have the opportunity to contribute". A teleconference could also be used for a "problem clinic" where mentees bring forward their live problems for consultation either with their mentor alone or with other mentees.

## ICSB Conference – Washington – June 2005

Stokes *et. al.* (2003) are critical of Perren's review and the contributions that existing research makes to e-mentoring. The emerging view is that current research falls short of a robust evaluation of the area, largely due to the lack of data. Those who have published on the subject have tended to balance low cost and flexibility of e-mentoring schemes against the limitations that e-mentoring has when dealing with more complex interpersonal issues. As a result, there have been calls for e-mentoring to be seen as a supplement to, but not a substitute for face to face mentoring. However, the paucity of research limits the extent to which this can be claimed with confidence.

Beech & Brockbank (1999) offer another perspective when considering the issue of power and how the imbalance of power may be overcome through e-mentoring. They consider how face-to-face interactions may be distracted by visual clues, and issues related to setting, context, and atmosphere may hamper communication. They conclude that as e-mail and text based messaging are leaner communication channels that allow for more direct information transfer, it could remove contextual issues.

Stokes *et.al.* (2003), raise a number of questions, specifically about e-mentoring. Firstly, can e-mentoring - as an alternative mode of mentoring – enable mentoring relationships of sufficient depth and quality so that benefits can be gained? Related to that question, we can also ask whether e-mentoring can overcome some of the difficulties experienced in traditional didactic mentoring relationships. If the answer to both questions is 'yes' then e-mentoring has a great deal to offer to the field of mentoring and coaching.

However Stokes *et. al.* (2003) conclude that e-mentoring, due to the 'leanness' of text based communication, might compel the participants to focus more on the substance of the

## ICSB Conference – Washington – June 2005

message than on the style, status etc of the person delivering it. This therefore adds an additional research question to those already contributed: can e-mentoring offer additional benefits which go beyond those offered by traditional mentoring? Stokes *et. al.* (2003) cites Hawkrigde's, 2003 article, which is based on his eighteen years experience with the Open University, offers some additional ways in which text based communication might hold sway over face-to-face interaction. These advantages seem to stem from the recordable nature of the text which, unless special effort is made to record face to face sessions, is not usually used in those sorts of interactions. As the text is available, this enables all parties to make sense of the contributions by "synthesising and summarising, drawing threads together, watching for and correcting conversational drift, spotting good ideas" and so on. Bierema and Merriam (2002) point out, in the case of mentoring, "successful mentoring involves frequent and regular interaction" but that "all sorts of barriers such as time, work responsibilities, geographical distance and lack of trust often reduce if not halt interaction" (p214). E-Mentoring merges the approach of the traditional mentoring relationship with technology, and is increasingly used as the preferred choice of communication, Realm (2002)

It has become apparent from the literature that many authors believe E-Mentoring is a suitable means of support for the traditional physical mentoring relationships, rather than a relationship that exists solely through the use of technology. The definitions offered earlier also appear to be inappropriate, this one offered by Hunt, (2004a) starts to narrow it down:

*"E-Mentoring uses technology to facilitate the development of a supportive relationship for experimentation & personal development in a safe, convenient & timely environment; helping both mentee & mentor to grow"*

## ICSB Conference – Washington – June 2005

Hunt (2005) has gone on to provide a tighter definition, which is widely used for the MentorsByNet programme and other programs that he has been involved with:

*“Utilizing technology, E-Mentoring is the process by which two people assist each other to grow and learn in a safe and supportive relationship”.*

For the future, Clutterbuck (2004) believes we are likely to use a blend of methods and technologies to improve the mentoring process.

*‘As technology becomes more sophisticated it is reasonable to assume there will be much broader and more intelligent use of technologies. There will, in particular, be much more use of videoconferencing, through desktop PCs and web cameras. In the future, it seems likely that the majority of mentoring relationships will be hybrids of face-to-face in person, synchronous face-to-face remote and asynchronous textual exchanges. The evidence suggests that this has great potential to enrich the dialogue between mentor and mentee. Mentoring scheme co-ordinators will have to include the effective use of these technologies as an integral part of mentor and mentee training.’*

It is already possible to see some of the features that a face-to-face and e-mentoring relationships share, such as:

- A caring relationship
- Fostering of the person's skills by a more experienced person
- Ongoing, regular communication

## ICSB Conference – Washington – June 2005

- Trust, warmth and support
- Clear boundaries of the parameters of the mentoring relationship
- Administration by an organization that oversees the mentoring relationships

However we can also begin to see where e-mentoring differs from traditional face-to-face mentoring in a number of ways:

- Location is not an issue
- A record of the discussion will exist (saved emails) facilitating reflection
- Communication occurs mostly through e-mail
- Relationships are often time-limited
- Mentors can often engage in e-mentoring during their work day or when it is convenient.
- E-mentoring offers the convenience of communicating online
- A large number of communication methods can be utilised:
  - Telephone
  - Desk top video conferencing
  - Email
  - Discussion rooms
  - Instant relay chat
  - Etc.

# ICSB Conference – Washington – June 2005

## EVALUATION APPROACH

The data used for this evaluation comes from two distinct stages, pilot programme and full programme.

### Evaluation Approach – Pilot Programme

The evaluation was carried out in two phases - in the form of pre- and post-programme e-mailed questionnaires. The questionnaires were based on the one sent out by APESMA<sup>4</sup> (Australia), for comparative purposes, as well as covering additional aspects that were of interest to the sponsors of MentorsByNet and the researchers. On both occasions the questionnaires were sent out to mentees and to mentors in parallel, but worded differently.

The decision to send out both a pre- and post-questionnaire, for the pilot, instead of just a post-programme one was founded on the desire to evaluate and compare pre-programme expectations with post-programme views grounded in their experience.

A preliminary analysis of the pre-programme questionnaires was undertaken using the industry standard computer package for analysing data called SPSS. A preliminary report was then produced. The data was analysed looking at both frequency of response as well as any significant correlations using the Spearman rho method.

### Evaluation Approach – Full Programme

Pre programme expectation data is now captured routinely as part of the registration process that both mentors and mentees undertake. This data is then held within the database for subsequent use and investigation.

---

<sup>4</sup> Association of Professional Engineers, Scientists & Managers, Australia

# ICSB Conference – Washington – June 2005

MentorsByNet now secure information from participants through electronic questionnaires based on the 'post programme' one used for the pilot stage to ensure comparability, at two distinct stages. The first questionnaire is circulated about 4 weeks after the mentor and mentee have been notified of their e-mentoring relationship. The second questionnaire is post programme participation and is circulated at the end of the 6 months.

The data from both these questionnaires and the registration process is evaluated in line with the processes adopted for the pilot programme.

## OVERVIEW OF MENTORSBYNET

MentorsByNet programme was designed by the author around the 5M's principles shown below :

| <b>The 5M's of E-Mentoring</b>                             |   |  |
|--|---|--|
| <b>5 M's</b>   | <b>Objective</b>  | <b>Outcome</b>   |
| <b>M</b> arketing<br><b>P</b> rocess                       | Clearly understand the marketing implications to enable the programme to gain sufficient number of relevant Mentors and participant Mentees. These will differ from programme to programme.   | Sufficient Numbers in Scheme                                       |

MentorsByNet has now developed into a very sophisticated model from the early days, far too complex to describe fully here, but some of the key elements of the processes are listed below:

- It works with and through established business support organisations.
  
- All participants register online
  - Core data
  - Freeform data for expectations
  - Skills matrix for matching
  
- Mentors undertake an Online Self Assessment against 7 core competencies<sup>5</sup>
  
- Mentors & Mentee undertake online training against the 7 core competencies<sup>6</sup>
  
- Mentors & Mentees are matched using a range of data provided during registration and updated by the participant during the training:
  - Primary data for the matching comes from the skills matrix and identified needs for development

---

<sup>5</sup> The online Mentor Self Assessment programme was developed by Kevin Hunt & Dr Robert Garvey of Sheffield Hallam University, Mentoring & Coaching Unit UK.

<sup>6</sup> The online Training programme originally developed by Prof. David Clutterbuck of Clutterbuck Associates and was redeveloped by Kevin Hunt & Dr Robert Garvey of Sheffield Hallam University, Mentoring & Coaching Unit UK to address the 7 core competencies that they identified were needed in the mentoring relationship.

# ICSB Conference – Washington – June 2005

- The early stages of the relationship is monitored through email activity as initial contacts use a @mentorsbynet email address to route through the secure server. This stage is facilitated through email interaction with the programme delivery team.
- The relationship is planned to last about 6 months and will go through the 4 stages of the mentoring relationship.
- During the developing stage of the relationship participants are offered a ‘no fault divorce’ if it is felt that the match is not working as well as it could.
- Facilitation is then evident at the closing stages of the relationship to help manage the final stage and to provide information for further support.

The MentorsByNet programme is actively managed and relationships facilitated throughout the programme, evaluation material and feedback is secured at key points within the process which has led directly to many of the enhancements that the programme now benefits from.

## **RESULTS & DISCUSSION**

### Profile of Participants

At the time of the evaluation MentorsByNet had attracted a total of 517 participants. As *Table 1*, shows the gender split between mentees were 37% women and 63% men, whilst the mentors were 19% women and 81% men.

| MENTEES |       | MENTORS |       | TOTAL |
|---------|-------|---------|-------|-------|
| Men     | Women | Men     | Women |       |
| 205     | 120   | 154     | 38    | 517   |

Table 1: Gender Profile of Participants

## ICSB Conference – Washington – June 2005

Whilst this presents a balanced picture for mentors in relation to the business ownership with the UK demonstrating around 17% of SMEs are owned or led by women, SBS (2004), Carter, Anderson & Shaw (2003). However it does show that the programme has been more successful in attracting women mentees to participate, 37%, although the programme was not gender orientated in its marketing approach.

The research also took into account the location of the participants, splitting this between urban based locations and rural based locations. Whilst there is a natural tenancy for the programme to attract participants from urban locations due to the higher density, we can see from *Table 2*, that 64% of mentees and 59% of mentors were urban based.

| MENTEES |       | MENTORS |       | TOTAL |
|---------|-------|---------|-------|-------|
| Urban   | Rural | Urban   | Rural |       |
| 208     | 117   | 114     | 78    | 517   |

Table 2: Location of Participants

It has been argued the E-Mentoring is more suited to participants based in rural and isolated locations, often quoting distance as a reason Hunt (2004b & 2004c), but this programme appears to demonstrate that E-Mentoring is equally as popular with urban based entrepreneurs, if not more so.

This demonstrates a need for further research to look at the motivation for the decision to participate in this type of programme.

| MENTEES |       |       |       |       |       |     |            |
|---------|-------|-------|-------|-------|-------|-----|------------|
|         | 16-19 | 20-29 | 30-39 | 40-49 | 50-59 | 60+ | Not Stated |
| Women   | 0%    | 7%    | 30%   | 36%   | 19%   | 2%  | 7%         |
| Men     | 1%    | 10%   | 26%   | 36%   | 15%   | 6%  | 7%         |

## ICSB Conference – Washington – June 2005

| MENTORS |       |       |       |       |       |     |            |
|---------|-------|-------|-------|-------|-------|-----|------------|
|         | 16-19 | 20-29 | 30-39 | 40-49 | 50-59 | 60+ | Not Stated |
| Women   | 0%    | 3%    | 30%   | 32%   | 24%   | 5%  | 5%         |
| Men     | 0%    | 1%    | 8%    | 27%   | 42%   | 20% | 3%         |

Table 3: Age Profile of Participants in Years

It can be seen from Table 3, that the age profile for the mentees is broadly similar with over 50% of the participants falling between the ages of 30 and 49 years, irrespective of gender. However the age profile for mentors shows 65% of women mentors are under 50 years of age whilst only 36% of the men fall into the same age bracket. This could be for a number of reasons, such as men tend to volunteer as they near retirement, a higher percentage of women are now becoming self employed at a younger age etc. but the responses to the questionnaires did not provide an insight into this question.

MentorsByNet is a voluntary programme where mentees were not charged and mentors received no income or expenses. It was an objective of the programme to secure volunteer mentors who were still actively engaged in running their business, to this end 78% of the mentors described themselves as owners of an SME. The balance was a mix between retired owners and active managers in larger organisations. All mentees were either owners of SMEs or were in the pre-start stages of their business.

### Summary of Key Findings

Before moving on to the key findings the following general point should be noted. Whilst there was a 'reasonable' return rate (approximately 45%) of evaluation questionnaires, compared with a typical response rate of 30%, it should nevertheless be pointed out that a significant number of scheme participants did not return their evaluation forms. Thus it is

## ICSB Conference – Washington – June 2005

difficult to tell what that means in terms of the views of the scheme as this set of participants have not articulated their views, thus tempering any general conclusions that can be drawn.

Post participation evaluation questionnaires are sent out to all participants at the conclusion of their e-mentoring relationship; this involved some 248 of which 45% returned usable data. This was split 60 mentees, 51 mentors and all figures subsequent quoted in this paper are as a percentage of the respondents to the survey.

One significant factor appears to be the use of facilitator's messaging to participants was used to prompt and direct the activities of participants and to 'keep them on track'. This approach has both strengths and weaknesses. On the one hand, it appears to have the effect of ensuring that mentees get the 'advice' they were seeking, on the other hand, many writers in the area (e.g. Garvey, 1995, Clutterbuck & Megginson, 1998) have emphasised the importance of voluntarism and uniqueness in mentoring relationships and have cautioned against being too prescriptive and standard-driven about the advice given. However, it is beyond the scope of this current study to examine the longer term effect of these different orientations.

The following are some of the key points:

- Over 90% of respondents felt that the programme was beneficial and stated they would recommend it to colleagues. In broad terms, the benefits gained conformed to what the mentees had expected in terms of being able to bounce ideas off a neutral party.

## ICSB Conference – Washington – June 2005

- 88.3% of respondents felt that the frequency of contact, which varied greatly, met, or totally met, their needs.
- 83.3% of responding mentees felt they had achieved their objectives. Where the objectives were not achieved, the duration of the relationship and 'my objectives changed during the relationship' were the most cited reasons.
- Contrastingly only 60.8% of the mentors felt that their mentees had achieved their objectives. This raises the question of perception and clarity of goals that would need to be investigated further.
- 100% of the mentees felt that the 6 month time limit on the programme was correct, whilst only 72.5% of mentors would agree.
- Over 50% of mentees said they would like continue in the e-mentoring relationship. Contrary to the previous point in which the participants felt 6 months was sufficient, this indicates that a longer period may have been required.
- Over 90% of mentees rated their mentor as good or very good in terms of both their skills and experience, and their overall performance during the e-mentoring relationship
- There was an increased willingness from both mentees (22% increase to 96%) and mentors (11% increase to 79%) to recommend the scheme to colleagues and peers post-programme.
- Generally participants felt that e-mentoring enabled integration of the programme into the mentees day-to-day activity, which would assist in their development and learning

## ICSB Conference – Washington – June 2005

- 91% of mentors and 82% of mentees indicated a substantial satisfaction rating with the respective mentoring partner
- 100% of mentees pre-programme expected to develop a good relationship with their mentors; post-programme 96% reported they had. Pre-programme 90% of mentors had the same expectation; post-programme this had decreased to 79%.
- In the pre-programme questionnaire 84% of mentees affirmed that the fact that MentorsByNet was an email-based programme encouraged them to participate. Post-programme mentee response had slightly increased to 90%.

The programme is still in progress so the foregoing results should be considered as interim. Irrespective there is now sufficient evidence that suggests MentorsByNet is successful and meeting its overall objectives. But there are still a number of questions that remain unanswered such as:

- What are the views of the 55% of non responses?
- Why the programme appears more successful, than traditional business support programmes, at attracting women mentees?
- What are the motivations for participation?

None of these are likely to detract from the results presented here, but do remain considerations for the future.

Based on the results reported MentorsByNet e-mentoring programme appears to be able to deliver benefits for participants that are directly comparable to the more traditional face-to-face approach. In addition a number of other benefits have emerged, such as:

## ICSB Conference – Washington – June 2005

- Allows for the propagation of mentoring in the small business sector, which is widely seen as effective, as valuable sources of on-going management development.
- It appears that the absence of visual cues remove some potential barriers e.g. gender or status and permits concentration on key issues.
- E-Mentoring allows for remote meetings that are time and space independent
- There appears to be no loss of relationship between communications
- Asynchronous communication encourages reflection, allowing mentee and mentor to record, focus on, and to return to issues and to spend more time on them
- Email based mentoring appears to be good for communication of information, ideas and developing an analytical and questioning approach
- Mentor and mentee able to communicate whenever is convenient.
- E-mentoring may suit those for whom face to face meetings produce anxiety.
- Based on satisfaction levels the approach taken by MentorsByNet demonstrates a higher tendency for mentors and mentees to be paired correctly and less extraction complications.
- MentorsByNet has shown that it is able to recruit mentors who are still working vs. retired.

### CONCLUSIONS

Whilst there remains much debate over the true value of face-to-face mentoring versus E-Mentoring there is now growing evidence to suggest that, as a minimum, the same levels of

## ICSB Conference – Washington – June 2005

benefits for the mentee are possible through E-Mentoring alone. There is further evidence to suggest that additional benefits are being recognised by E-Mentoring participants, not least issues like convenience, timely, peer pressure reduction to name a few. There is emerging evidence that suggests certain groups of the business population find this approach more appropriate, such as women. There is little to suggest that E-Mentoring does not work.

It appears, as with any other mentoring programme, the benefits for the participants are enhanced by the quality of the overall programme. MentorsByNet is well run and has been developed to aid the quality of the programme with feature such as the On-Line Self Assessment, 7 Core Modules of Training, the matching matrix and facilitation of relationship etc. The quality of the key features and the professional delivery of the programme contribute greatly to the results achieved, thus it would not be fair to conclude that all e-mentoring programmes can offer the same or greater benefits over the more traditionally recognised approach. But it is possible to conclude that were these factors are present and combine then E-Mentoring is an effective approach to mentoring in today's business world.

This paper has also high lighted some areas that could benefit from further research, areas such as the motivation factors affecting the decision of the participants to join an e-mentoring programme over a face-to-face, such as gender differences or rural versus urban participation. The following are a few of the comments received from the evaluation questionnaires from the participants that appear to support, in general, these conclusions:

*"E-mentoring has definitely improved the quality of my business management processes as it has allowed me to tap a collective pool of knowledge that has been built up over dozens of years". (Mentee)*

*"E-mentoring is not a process which lends itself to infrequent lengthy meetings, with formal agendas. It's more about providing a sounding board or a shoulder to lean on. When these*

## ICSB Conference – Washington – June 2005

*things are needed, they're needed virtually as the thought arises and not in a week's time. That's the beauty of E-mentoring". (Mentor)*

*"Discussing issues with our mentor has given us self belief and encouragement, plus a great network of people to discuss various aspects of the business with". (Mentee)*

*"I have found the Mentoring role causes me to question the way I do/view things and to that extent it is potentially as beneficial to me as to the mentees" B.L. Mentor*

*"It has given me more confidence and improved my skills" R.R. Mentee*

*"As mine is a fairly new business and it is certainly expanding, it has been a great help to me to be able to discuss the business with someone. It has helped me to solve some problems and avoid possible pitfalls." J.A. Mentee*

*"Very useful for both myself as a mentor and hopefully the mentee, can we continue" S.B. Mentor*

*"A great system, thank you very much" J.H. Mentee*

*"It has been so valuable to take time out and evaluate where I am up to and what next." D.C. Mentee*

*"The business is growing in turnover and profitability, some of which can be attributed to the mentoring. The key benefit has been with regard to the longer term potential of the company, the results of which will not be evident for some time." B.R. Mentee*

*"We have worked well together as I was able to bring relevant experience to the party" J.R. Mentor*

*"As a start-up outside the commercial sector it was useful to have an experienced commercial manager giving a perspective... Thanks to you for such a good and organized programme." P.J. Mentee*

*"It provided me with an experienced sounding board and some good business tactics." P.D. Mentee*

*"It has given me personal satisfaction to be able to help two people who felt the need for objective, independent support from someone with no 'agenda'." A.J. Mentor*

*"I have now realised how beneficial a mentor could be if the mentee approaches the relationship with commitment." D. W. Mentee*

*"A very worthwhile relationship & thank you for your assistance." A. G. Mentee*

### **ABSTRACT**

The firms that locate within the incubators (incubatees) are not a homogeneous group but they differ in age, size, industry, phase of development and firm strategy. After the years of investing in the premises and walls, the Finnish incubators are currently focusing on the development of their services. Simultaneously, they should consider which firms benefit most from these services. The incubators should be able to segment the firms in order to provide the right services for the right firms. In addition, they should also be aware what types of services are beneficial for the different firms at the different phases of development. In Scandinavia and in Europe the incubators are in most cases a policy-measure financed by the public sector. Hence, from the policy perspective it is important to make sure that the most 'promising' firms will benefit from the incubator. Our results suggest that younger firms that have developed fast and not prolonged their stay in the incubator benefit most from the incubators. Hence, alternative tools for traditional life-cycle based models in firm the development are needed to provide better benefits for the “superstars” and to activate the other customer segments in the incubator.

### **INTRODUCTION**

Promoting entrepreneurship and growth of companies is one of the most important aims for the industrial and entrepreneurship policies in Finland and in Europe. There are several instruments that aim at fostering entrepreneurship and growth. In this paper we will focus on the technology incubators<sup>1</sup>. Technology incubators have become common in all of the Western countries but also lately, for example, in Asia. The term incubator can be used to refer to several different types of organisations that aim at assisting entrepreneurs or aspiring entrepreneurs to commercialise their idea and to set up a company. In its broadest sense the incubators include science parks, business and innovation centres and organisations that coordinate services without physical presence ('incubators without walls'). According to a narrower definition:

*'A business incubator is an organisation that accelerates and systematises the process of creating successful enterprises by providing them with a comprehensive and integrated range of support, including: Incubator space, business support services, and clustering and networking services'. (European Commission 2002, 9.)*

---

<sup>1</sup>For further discussion on the typologies refer to Grimaldi – Grandi 2005, Chan – Lau 2005, Surlemont et al 2002.

In this study we use the term incubator to refer to organisations that provide *business services to new technology-based firms* (NTBFs). These services are produced by the incubator management or purchased from the incubator network service providers. The incubatees can either locate in the incubator premises or in other premises. The incubators that do not offer premises for their incubatees are called ‘virtual incubators’. (Tilburg et al 2002, also Nowak – Grantham 2000) In this paper, we will focus technology incubators and their role in promoting new technology based firms (NTBFs).

The technology incubators request their incubatees to have a high technology level and they provide high-level management support for the companies. Currently, there is a strong focus to develop these services and support for the firms to achieve the best possible effectiveness. The purpose of this study is, firstly, *to find out what companies seem to benefit most from their location in the incubator*. Secondly, we investigate *if the firms that should benefit most from the incubator - the ‘superstars’ - are actually able to claim these benefits*.

## **SERVICES PROVIDED BY THE INCUBATOR**

The task for the incubators is to complement the existing resources of the incubatees: human resources (by developing the existing resources through training or by assisting in recruiting), social resources (by facilitating access to networks within the incubator/science park or to external networks), financial resources (information about and contacts to financiers), physical resources (premises, machines, etc.), technological resources (access to technology) and organisational resources (counselling, consulting and mentoring). (Sijde, 2002).

Based on the study by Chan and Lau (2004) the main reasons for the incubatees to locate themselves in an incubator are connected to costs, especially for the firms active in the R&D process. Furthermore, the joint staff development and training and marketing events were important reasons to stay in the incubator. Furthermore, sharing of joint resources (e.g. the premises, library) were also important perceived benefits for most of the firms in the different phases of development. The firms also needed to develop their business competences and expressed a need for related consulting. The unwillingness to share information was hampering the full use of the services. R&D consulting was not a main motivator for the firms due to expertise in their own areas. The firms did not perceive to benefit much from the networking or clustering services. Similarly, the image benefits connected to the location in the science park or incubator were also not recognised. In the study it was also emphasised that the expected benefits from the incubator change over time as a consequence of the phase of development of the firm. (Chan & Lau 2004, also Ferguson 1999)

## **DATA, METHODOLOGY AND ANALYSIS**

### **Data and Measures**

The research question was operationalised by investigating if firm age, size, industry, phase of development, growth of the firm or the length of the incubating period

(=independent variables) are connected with the use of the incubator services, needs for the incubator, satisfaction with the incubator, expectations for the incubator and the perceived effects of the incubator (=dependent variables). (See Appendix 2). In order to catch a general view on the firms' perceptions of benefits from the incubator and in order to find out which factors should be taken into a closer consideration in the future, we used a series of logistic regression analysis. We are aware that this is a quite unusual method as normally only one or in maximum a few logistic regression models are developed in a study. However, in this phase when we have a very rich body of data and the phenomena is quite unexplored we found it very useful. With this explorative analysis we aim at contributing to the development of measures for the effectiveness of incubators<sup>2</sup>. A logistic regression analysis was conducted firstly by including the independent continuous variables in the model as such and by including alternative variables (variables that had a high correlation) one by one in the model in order to eliminate the problems of multi-collinearity. Then the independent variables were classified and the same analyses were conducted in order to see, whether there are also non-linear correlations between the dependent and independent variables. In general, the independent variables explained the dependent variables better when classified (which suggests that the correlations in our data are in many cases non-linear) and we ended up using a model with classified independent variables. The final analysis was conducted by including all the variables in the model simultaneously (Enter method) and also by applying Forward Wald method. In the interpretation we have applied both the analyses in order to find as many explanations for the above issues as possible.

The firms' basic characteristics are presented in the table below.

**Table 1 Presentation of the incubatees investigated, N = 131**

| <b>Characteristic</b>                          | <b>Average</b>  | <b>Mode</b> | <b>Min</b> | <b>Max</b>    |
|--|---|-------------|------------|---------------|

## Results of the study

<sup>2</sup> Refer to for further discussion on the measures of incubator success (Hackett – Dilts 2004).

In order to find out what firms seem to benefit most from their location in the incubator we studied the incubatees' use of services and perceptions of the benefits induced by the incubator. In general, the most frequently used services are premises, office services and related services, business development services and consultation, juridical services, and financial services and consultation. Recruitment services, mentoring and other senior advisory services, as well as internationalization services and consultation are services used most infrequently. The incubatees are in general fairly satisfied with the incubator and the incubator management. The business development services are an important motive for the firms for their location in the incubator and the firms perceive to benefit mostly from the business development services, especially from the start-up services and financial guidance and counselling as well as from financing. Furthermore, the firms' expectations for the future are also most frequently targeted at the business development services.

The use of certain services is connected to the firm *age*. The use of R&D, patenting and licensing services as well as mentoring, board members and other services is most typical for the firms that are between 2–3 years. The most satisfied customers are the firms under 3 years of age. Satisfaction with the business development services is more likely among firms that are under 4 years, and firms that are under 2 years mention these services as an important value added of the incubator more likely than older firms. The firms that are 3 years or more are less likely to hold that the relation with the incubator would generate any value added for the firm. The *length of the incubating period* is connected to the needs for the incubator and satisfaction with the incubator. The firms that have operated in the incubator under a year emphasise networks and contacts as a reason for their connection with the incubator. Especially the firms that have operated 2–3 years in the incubator are eager to criticise the practices, characteristics or skills of the incubator staff. Furthermore, the satisfaction with the incubator decreases along the stay in the incubator. We have also noted elsewhere that the prolonged stay in the incubator decreases the likelihood for employment growth among the new technology based firms. (Mäki – Hytti 2005)

Firm *size* did not explain the ability to benefit from the incubator in the same way than the firm age. Mentoring and other senior advisory services seems to be more typical for the firms employing under 2 persons and business development services and consultation for the firms employing 2–5 persons. The firms that employ 2 or more persons are less likely to hold that their connection with the incubator would generate any value added for the firm. This result suggests that the incubators contribute more for the development of the smallest firms.

In most cases the *industry* did not explain any differences. However, the use of R&D, patenting and licensing services is more typical for firms operating in life sciences sector and other technology sectors (than in ICT and life sciences). The firms operating in life sciences and other technology sectors also have more often expectations for the premises and related services. As there were no differences in the satisfaction with the incubator among the firms in the different industries we may conclude that the incubators are able

to answer to the needs of the incubatees despite their industry. Hence, our results do not support the need for strong industry-based specialisation of the incubators.

To sum up, it seems that the younger firms (basically three years of age at maximum) that have not extended their stay in the incubator for over two or three years perceive to benefit most from the incubator. The firm size and industry did not remarkably distinguish the perceptions of the firms.

Secondly, we were interested if the most 'promising' firms actually perceive to benefit the most from the incubator as is expected by the policy-makers. This was done by asking the incubator managers to classify the firms into classes A, B and C based on their assessment of e.g. growth, internationalisation and venture capital investment potential of the firm. This classification was validated by cross-tabulating the three-class variable with the basic characteristics of the firm. The analysis confirmed that the A-class firms were the most developed firms, B-class firms came second and C-class firms third. The classification correlated with the firm size (number of entrepreneurs as well as employees), industry, internationalization, growth-orientation and funding patterns of the firm. Thus, although the indicator aims at measuring merely the potential of the firm, the analysis indicates that it might actually predict quite well the actual development of the firm. In addition, we were also interested to investigate the already proven success of the firms. Although it is suggested elsewhere that the incubatees grow only after they graduate from the incubator (Ferguson 2004), we have identified different growth firms already in the clientele of the incubators. Elsewhere (Mäki & Hytti 2005), we have developed growth indicators suitable for examining the growth of incubatees or new technology based firms in general<sup>3</sup>. The firms that had an annual growth of 2 employees or turnover growth of 150.000 euros annually were classified as growth firms. There was no correlation between the growth of the firm and the ABC -classification.

The analysis shows that the most promising firms (A-class firms) use certain services more often than the B- and C-class firms. These services include R&D services, juridical services, marketing and sales consultation and services, internationalisation consultation and services, recruitment, mentoring and other senior advisory services. In order to serve better the A-class firms the incubators should put a stronger emphasis on these services, especially because of these services juridical services, internationalisation services, recruitment services as well as mentoring and senior advisory services were given worse grades than the other services by the firms. (Hytti – Mäki – Akola 2004). From the perspective of the incubator staff this is particularly challenging as many of these services (incl. internationalization services and consultation; recruitment, mentoring and other

---

<sup>3</sup> The use of proportional growth indicators is problematic because in the beginning the turnover and employment is often 0. Another problem with proportional indicators is that they favour the smallest companies. Our analysis suggests that in the analysis of growth of new technology based firms absolute growth indicators might be more useful than proportional growth figures. Overall the age structure of the firms hampers the growth analyses. Firstly, it may not be possible to have actual and reliable growth figures from three consecutive years because the firms are young. Secondly, the business operations often start gradually by the efforts of the entrepreneur and growth in some scale is considered necessary anyway to even achieve the breakeven point. (For this reason it would be necessary to investigate growth by taking into account profitability in the start-up companies.)

senior advisory services) are also used quite infrequently in general. The infrequent use – and hence, also supply – of these services could also be the reason for the worse grades: lack of practice, routines and knowledge may cause distortions in the service process. Similarly to the “A-class firms”, the *firms that had grown* by employment also use more often mentoring and senior advisory services (see above). These growth firms had typically joined the incubator to take advantage of the start-up services and less often to get funding. The growth firms also put less emphasis on the premises and the related services as a particular value added created by the incubator and they also have fewer expectations for the premises and the related services. The results suggest that the premises are more important for the firms growing slowly than for the growth firms.

To sum up, the most successful and promising firms were as satisfied with the incubator as the other incubatees. Thus, we cannot in this sense conclude that the incubators should focus more on satisfying these clients in general. On the other hand, it is necessary to understand that both the satisfaction and dissatisfaction of these firms would be difficult to interpret from the point of view of the incubators. Even if the firms were satisfied, we would not know whether this is due to the activities of the incubator or their own success. The dissatisfaction, on the other hand, could be interpreted as higher demands and better ability to judge the incubator activities. More importantly, however, on the basis of the analysis we can conclude that if the incubators are supposed to provide the best possible services to the most successful or promising firms they should pay more attention to the services that these firms use.

## **Conclusions**

In the literature it is possible to identify different incubator profiles (Grimaldi – Grandi 2005, Chan – Lau 2005, Surlemont et al 2002). In this paper we have focused on technology incubators that request their incubatees to have a high technology level and in return are committed to providing intensive business development services for the firms. Nevertheless, the incubatees residing in the technology incubators are not a homogeneous group but they differ in age, size, industry, phase of development and firm strategy. In this paper we have analysed, firstly, which characteristics really distinguish the incubator firms and which firms benefit most from their location in the incubator. Secondly, we have analysed if the firms that should benefit most from the incubator, i.e. the already successful firms as well as the most promising firms, can actually claim these benefits.

Based on our findings, the firm size and industry did not distinguish the perceptions of the firms. It is the relative young firms (under 3 years of age) that seem to benefit most from their location in the incubator. The firms that have an incubating period of less than two years seem to benefit most from the incubator. Furthermore, as the firms that have stayed in the incubator longer are not likely to grow their number of employees (Mäki – Hytti 2005), we may conclude that prolonging the incubating period would not be recommendable. As a result, it is suggested that continuous attention is given to the optimisation of the incubating periods. We suggest that instead of fixed incubating periods (generally from 1-3 years in Finland) the incubators would develop ‘graduation criterion’ for the firms as the heterogeneity of the firms might also be reflected in the

optimal incubation periods for each firm. The graduation criterion should also include incentives for the firms. It is suggested that continuous effort is placed on the early stages of the firm, for example, by supporting strongly early-growth of the firms. This could be done by underlining the growth perspective already in the first business planning and strategy formation phase of the firm. The entrepreneurs with a background in a university or an R&D department are strongly motivated to developing the technology. Hence, the important task for the incubator is to underline continuously the need to reflect the market and customer side of the business. Based on our earlier study, the entrepreneurial teams are also more likely to develop and grow the firm than sole entrepreneurs (Mäki – Hytti 2005). Hence, team entrepreneurship might be an efficient way to increase the growth potential of the incubatees. By shortening and intensifying the incubating periods and by creating landmarks for the early and fast graduation it might be possible to increase the number of incubatees in the incubators over time, and consequently also the graduates and new technology-based firms, which is also the aim for the current Finnish policy.

The most successful firms or most promising firms were as satisfied with the incubators as the other incubatees. However, the A-class firms and the growth firms use business development services more than the other firms (Chan – Lau 2004). These services include R&D services; juridical services; marketing and sales consultation and services; internationalization consultation and services; recruitment, mentoring and senior advisory services. Based on the ratings given by the firms for these services, it seems that there remains some improvement possibilities in the quality of these services (e.g., juridical services, internationalisation services, recruitment as well as mentoring services and other senior advisory services). However, many of these services are used quite infrequently in general and, therefore, the challenge for the incubators lies in creating and developing the services processes. As the number of A-class firms requesting these services per an incubator is limited this might be problematic if the incubators do not intensify their co-operation and provide mutually organised services for the firms.

Therefore, our results confirm the earlier studies that business services need to be focused strongly in the incubator (Massey 1992, Phillimore 1999). Especially for the most successful and promising firms the business development services and consultation are the most important benefits that they can gain from the incubator. The premises and funding are also necessary and the incubatees willingly accept also these benefits but it is the business development services that make the difference.

*Limitations of the study:* As this study is based on cross-sectional data which does not include graduates from the incubators, the results are preliminary. If the graduates would have been included in the sample we might expect to have received an even more positive picture, and also more differences between the firms. A follow-up study will be conducted to investigate the firm development.

## **Appendix 1 List of groups of dependent variables**

### *Use of incubator services*

“What services of science park, incubator or some other service provider does your firm use?” Different services: Premises and related services; Office services; Firm founding related services and consultation; Firm development related services and consultation; R&D, patenting, licensing; Juridical services; Marketing and sales related services and consultation; Funding related services and consultation; Internationalization related services and consultation; Recruitment services; Mentoring and other use of senior advisors; Networking services/Structured question: “Uses continuously”; “Uses every now and then”; “Uses seldom” vs. “Does not use”.

### *Needs for incubator*

“Please mention three most important reasons for operating in the incubator”/Open ended question, classified: Networks and contacts/Premises and related services/Support services/Business development services/Location/Atmosphere and image/Practices, characteristics, skills/Other/None, does not know.

### *Satisfaction with incubator*

-“When considering incubator’s activities as a whole, what grade describes it best?”/Structured question, compressed: A vs. other grades.

-“Please mention three especially successful factors in the incubator”/Open ended question, classified: Networks and contacts/Premises and related services/Support services/Business development services/Location/Atmosphere and image/ Practices, characteristics, skills/Other/None, does not know.

-“Please mention three especially unsuccessful factors in the incubator”/Open ended question, classified: Networks and contacts/Premises and related services/Support services/Business development services/Location/Atmosphere and image/ Practices, characteristics, skills/Other/None, does not know.

### *Expectations for incubator*

“What kind of services and activities do you expect from the incubator in the future?”/Open ended question, classified: Networks and contacts/Premises and related services/Support services/Business development services/Location/Atmosphere and image/ Practices, characteristics, skills/Other/None, does not know.

### *Perspectives on effects of incubator*

-“What is the value added the incubator gives for the firm that the firm can not get anywhere else?”/Open ended question, classified: Networks and contacts/Premises and related services/Support services/Business development services/Location/Atmosphere and image/ Practices, characteristics, skills/Other/None, does not know.

-“If the incubator did not exist, would your firm be founded in any case?”/Structured question: “Probably yes”; “Probably no”; “No” vs. “Yes”.

-“How would you consider the following statement: “The incubator has accelerated the development of the firm”/Structured:question: “Yes, remarkably” vs. “Yes, to some extent”; “Yes, a little”; “No”.

## **ABSTRACT**

The Finnish universities have not focused on developing new entrepreneurs. University graduates have been underrepresented in the entrepreneur population in Finland. However, the group of university graduates is heterogeneous calling for investigations of the different sub-groups. The paper confirms earlier studies that the male persons at their prime-age (31-45 years) continue to be the most active group in terms of entrepreneurship and that the role of entrepreneurial role models in the family has a positive effect on the perceptions and intentions. Despite the risks attached to the dual-entrepreneur families, the role of the spouse is underlined in this study to have a positive influence on the personal desirability, feasibility and intent to start a firm. The university students find entrepreneurship both personally and generally desirable, which suggests that the entrepreneurial career in the future might become more typical for the university graduates. However, training and skill-development programmes might be necessary to increase the personal capabilities. Interestingly people with the background in business have more positive attitudes towards entrepreneurship than people with a background in engineering. Similarly, inter-disciplinary courses to include engineering and business students might be necessary to promote the entrepreneurial attitudes of the engineering students in order to promote more new technology-based start-ups. The paper suggests that there should be a continuous effort to promote female entrepreneurship. Furthermore, the third-age persons with the necessary social and financial capital could be targeted specifically to promote the positive attitudes and entrepreneurial intent, which would also support the current employment policies.

## **INTRODUCTION**

Traditionally Finnish universities have educated individuals for the public sector and large enterprises and the role of the Finnish universities has not been important in terms of developing future or current entrepreneurs. It is only recently that this role for the universities has been emphasised by the society due to the structural changes both at the private and public sector (flattening organisations, downsizing of the public sector). Nevertheless, there is still some controversy within the university sector of this role (see Paasio et al 2005). The university graduates are also underrepresented in the entrepreneurial population: There is a negative correlation between education and entrepreneurship in Finland: The more educated a person, the less likely she or he is to act as an entrepreneur albeit the positive attitudes towards entrepreneurship in general.

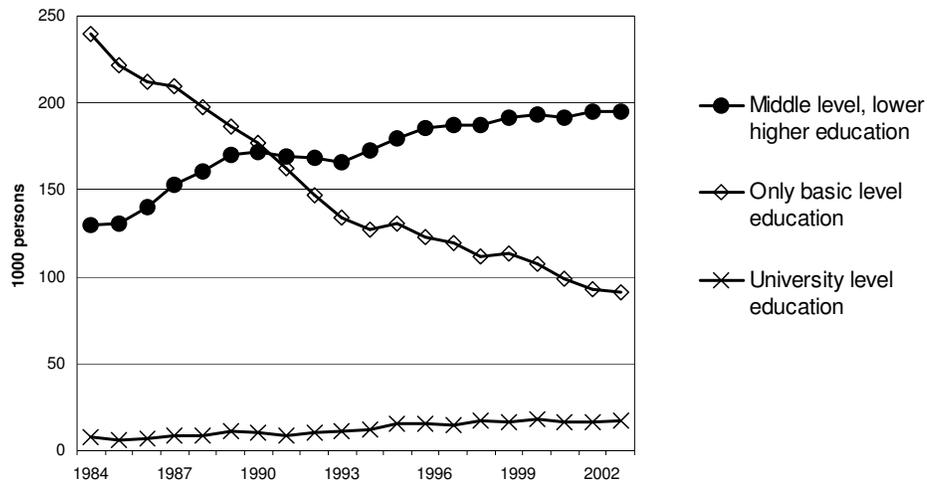

---

<sup>1</sup> Authors of the paper are in alphabetical order.

In this study, we are interested in how people with an academic degree perceive entrepreneurship as a personal career alternative. Nevertheless, we must acknowledge that the group of academic graduates is a highly heterogeneous one. In order to grasp these differences, we have selected the respondents from different groups in the study. First, we analyse how people that have graduated the university at different times perceive the alternative. Second, it is also interesting to examine how the future graduates that are currently studying at a university perceive entrepreneurship. Our expectation is that they should be more positive about the option than the older generations as the option is increasingly put forward as an alternative for people with an academic degree. Thirdly, there is currently a strong emphasis on the doctoral studies in Finland. The annual number of PhDs has doubled in the 1990s. For example, in 1995 there were about 800 PhDs which had grown into 1400 PhDs in 2004. At the same time it is assumed that the universities will not be able to absorb the growing number of PhDs into an academic career but they will increasingly need to seek other career options. For this reasons we are also investigating not only the basic degree students (M.Sc., B.Sc.) but also doctoral students and their perceptions of entrepreneurship. Fourthly, it is assumed that the different university disciplines will provide the students with different capabilities with regard to entrepreneurship. The respondents also represent different educational backgrounds: commercial, technical and natural sciences. As a result, we investigate how the background education will affect the entrepreneurial intentions of the respondents.

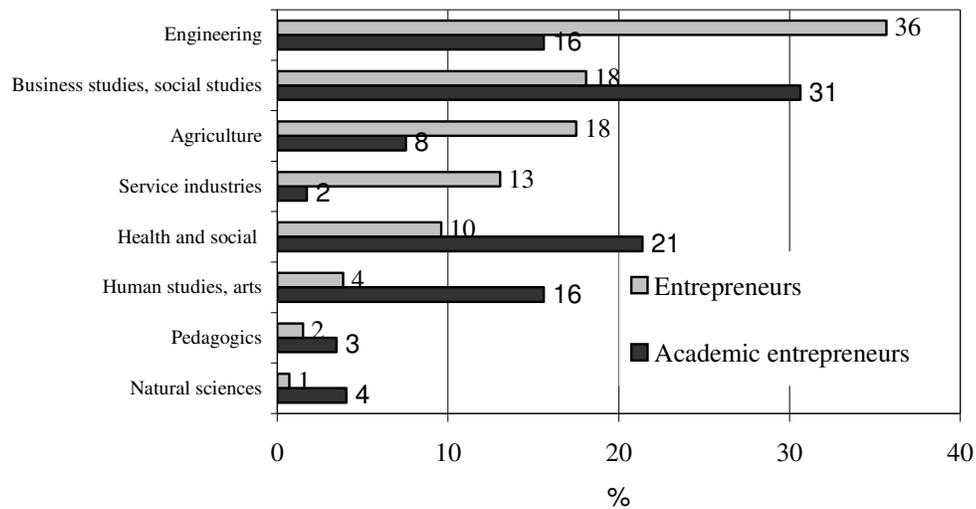

### **ENTREPRENEURSHIP AS A CAREER CHOICE FOR THE UNIVERSITY GRADUATE**

Recent research results suggest that Finnish people have very positive attitudes towards entrepreneurship in general but only few people have actual plans of setting up a firm (Arenius – Autio 2000, Arenius et al 2004). More particularly it is university graduates that are not interested of the entrepreneurial career. In fact, there is a negative correlation between education and entrepreneurship in Finland: The more educated a person, the less likely she or he is to act as an entrepreneur (see Figure 1). About 1/5 of the working population with a basic degree act as entrepreneur, while the share for the university graduates is only about 10% (Statistics Finland 2004).

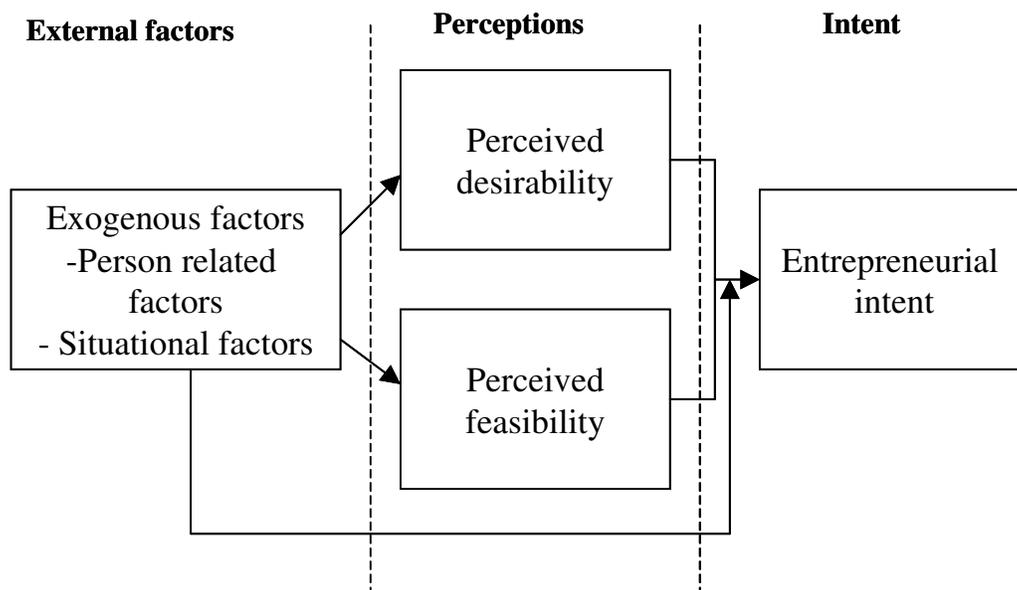

**Figure 1 The development of the number of entrepreneurs by level of education 1984-2004 (1000 persons), (Statistics Finland 2004, Paasio – Pukkinen 2005)**

There are also important variations between the different disciplines with regard to entrepreneurship. On average only about 1,3% of the students act as entrepreneurs after one year from graduation. However, in certain disciplines the average is much higher (20% of the dentists, 11,5% of the veterinaries). (Statistics Finland 2004, Paasio – Pukkinen 2005) It seems also that in certain disciplines the entrepreneurial activity is based on the level of education (Figure 2). For example, the entrepreneurial option is fairly usual for the people with a lower engineering degree while for the engineers with a university degree the option is less frequent. Within the business and social studies the trend seems to be opposite: the more educated persons act as entrepreneurs more frequently than the persons with a lower degree. The trend is similar for the natural sciences although with a much smaller proportion of entrepreneurs.

**Figure 2 Entrepreneurs and entrepreneurs with an academic degree by education, 2003, %**

The basis for the study is that becoming an entrepreneur is intentional, planned behaviour (Shapero – Sokol 1982, Krueger et al 2000, Rouvinen – Väänänen 2004, Grundstén 2004, Kolvereid 1996). Based on the theory the intent and behaviour are dependent on one hand on the perceived personal desirability and on the other hand on the perceived personal feasibility of the endeavour. These personal attitudes are affected by the personal and situational factors (Krueger 2000) such as educational background and working history. The framework for the study is presented in the figure 2.

**Figure 3 The process of model of entrepreneurship (adapted from Krueger 2000, Paasio – Pukkinen 2005)**

The aim of our study is to investigate how university students and graduates perceive entrepreneurship as a personal career alternative.

## METHODOLOGY AND ANALYSIS

### Data Gathering

For the purposes of this study a dataset was formed to include respondents from the following groups:

- Bachelor or Master’s degree students
  - Turku School of Economics and Business Administration (Finnish speaking business university in Turku), N=188
  - Åbo Akademi (Swedish-speaking university in Turku), N=76
- Doctoral students at the University of Turku
  - Participants at an Entrepreneurship Programme, N=56
- University graduates that work as employees
  - Members of the Finnish association of Graduates in Economics and Business Administration (SEFE), N=471
  - Members of The Finnish Association of Graduate Engineers (TEK), N= 374

### Data and Measures

#### *The dependent variables*

Entrepreneurial intent: How probable is it that you will start a firm within 5 years (scale 0-100)

Perceived personal desirability: How attractive would it be for you to start a firm? (scale 0-100)

Perceived personal feasibility: How easy would it be for you to start a firm? (scale 0-100)

[Perceived general desirability: How attractive is it for people in general to start a firm? (scale 0-100)]

[Perceived general feasibility: How feasible is it for people in general to start a firm? (scale 0-100)]

The independent variables:

- Sex (1=male)
- Age (1=under 30 years, 2=31-45 years, 3=over 46 years)
- Entrepreneurs in the family (grand-parents) (1=yes)
- Entrepreneurs in the family (parents) (1=yes)
- Entrepreneurs in the family (sisters, brothers) (1=yes)
- Entrepreneurs in the family (spouse) (1=yes)
- Entrepreneurs in the close networks (friends) (1=yes)
- Status (1=Student (M.Sc., B.Sc.), 2=Doctoral student, 3=Employee)
- Education (1=Business studies, 2=Engineering, 3=Natural sciences)

**Table 1 Presentation of the data**

| Sex   | n   | Age            | n   | Status          | n   | Education  | n   |
|-------|-----|----------------|-----|-----------------|-----|------------|-----|
| women | 529 | under 30 years | 446 | basic degree    | 260 | commercial | 659 |
| men   | 621 | 31-45 years    | 311 | doctoral degree | 56  | technical  | 446 |

|         |      |                  |      |              |      |                  |      |
|---------|------|------------------|------|--------------|------|------------------|------|
|         |      | 46 years of more | 400  | working life | 845  | natural sciences | 56   |
| missing | 11   | missing          | 4    | missing      | 0    | missing          | 0    |
| N       | 1161 |                  | 1161 |              | 1161 |                  | 1161 |

## Analysis

We conducted a logistic regression analysis on the relation of gender, age, entrepreneurial role models, status of the respondent (student, doctoral student or already in working life) and educational background towards perceived personal desirability, perceived personal feasibility and entrepreneurial intent. In addition, we conducted a logistic regression analysis on the relation of the above independent variables towards perceived general desirability and feasibility of entrepreneurship.

The relations were first analysed with SPSS Logistic Regression Enter method that includes all the variables in the model. We then iterated the model with Forward Wald method that excludes the variables not explaining the dependent variables. The stepwise analysis excluded some of the variables that appeared as statistically significant in the first phase but included also some new variables that were not statistically significant in case all the variables were included in the models. In the results we have chosen to apply the results from the Forward Wald method.

## RESULTS

The variables explaining the positive attitude towards perceived personal desirability and feasibility and entrepreneurial intent are listed in the table below.

**TABLE Logistic regression on positive attitudes towards perceived personal desirability and feasibility and entrepreneurial intent**

| N = 1161                                     | Perceived personal desirability |             | Perceived personal feasibility |             | Entrepreneurial intent |             |

Our results confirm earlier findings that entrepreneurship is predominantly a male activity. Men are about 2,5 times more likely to perceive entrepreneurship as personally desirable as well as feasible and similarly 2,5 times more like to start a firm in the next 5 years than women. The age of the respondents also explains the perceptions regarding entrepreneurship. The likelihood for finding entrepreneurship personally desirable increases for the young people (under 30 years) and prime-age people (31-45 years) compared to middle-aged and older people (over 45 years of

age). As expected, the likelihood for setting up a firm also increases for the prime-agers. People in this prime age group are two times more likely to start a firm within the next five years than the older generations in the study. Hence, the older generation (over 45 years of age) seem to be a 'lost case' in terms of entrepreneurship in Finland although from the point of view of social and financial capital needed for the venture they might be an interesting group (Blackburn – Hart 2004).

Similarly to previous studies the role of entrepreneurial role models (entrepreneurs in the family: parents, sisters and brothers) increases the likelihood for the entrepreneurial intent. More particularly the role of the spouse is underlined in the study: the spouse as an entrepreneur more than doubles the likelihood for the perceived personal desirability, feasibility and intent to set up the firm.

It also seems that the university study background effects the entrepreneurial intent: the students or graduates with an engineering background are less likely to set up a firm compared to students/graduates with a background in management or natural sciences. This is a surprising finding as one might expect that the engineering students and graduates to possess many technology- or knowledge-based ideas that could be the basis for a new venture. Management studies also increase the likelihood for the perceived feasibility which makes sense: they believe to be able to make business plans, manage employees, take care of the finances and all the other things considered necessary for running of the business. Interestingly, management studies also increase the likelihood for the perceived desirability of the entrepreneurial career.

Students (B.Sc., M.Sc., doctoral students) find entrepreneurship more desirable for themselves than people active in the working life. More importantly students also consider it to be a desirable and feasible career option for people in general. In this sense the students seem to consider entrepreneurship very positively. This might be the consequence of the strong emphasis of entrepreneurship in the studies currently and of the current policy debate in the society more generally. It is quite expected that the students do not yet have strong intentions of starting up the firm within the five next years as they presumably lack the necessary skills and experience. However, if the positive perceptions are sustained over the years we might be able to see more entrepreneurs with an academic degree in the future, which is an encouraging finding.

### **Limitations of the study**

For the purposes of this study we have combined a dataset where the respondents represent different groups in order to understand university graduates as a heterogeneous, rather than a homogeneous group. However, there are some problems with the dataset. The groups “natural sciences” and “doctoral students” are identical, hence, we do not have doctoral students in our sample to represent the other educational backgrounds and we do not have basic degree students or people in the working life that would have a background in natural sciences. In the future, we aim to form a more balanced dataset. Furthermore, the engineering students are all enrolled in one university and the business students in another university. Hence, the university per se might have an effect on their perceptions and intent and not only the discipline to be studied. This problem can be corrected by including also the management students in the first university in the sample to verify if there are differences between the disciplines. However, as the second university has a single

discipline (business studies), it is not possible to include engineering students from the other university in the sample. In this sense the group of graduates that includes graduates from all the universities in Finland is the most representative of the samples in our study.

## DISCUSSION

This study reinforces the earlier studies that entrepreneurship is predominantly a male activity. Men are more likely to set up a firm in the near future, perceive their own capabilities to be better in setting up the firm and perceive it to be personally a more desirable career alternative than women in our study. This message gives a clear indication to put a continuous effort on encouraging female entrepreneurship. Since based on an earlier study this finding holds true also when only students are targeted (Mäki – Korvela 2002), we believe that the universities have an important role to play in this regard. The possibilities provided by entrepreneurship to reach management position without the fear of reaching the ‘glass ceiling’ and to combine work and family life in a flexible manner might be the messages that the female students might find compelling. At the moment the image of the female students with regard to entrepreneurship might be biased towards ‘slave work and long hours’ that cannot be combined easily with a family.

Based on our study the persons in the younger or prime-age group are motivated by the entrepreneurial endeavour. In contrast, the older generation (over 45 years of age) seem a 'lost case' in terms of entrepreneurship, which raises some concern. Currently, there is an effort increase the number of employed persons by for example prolonging the working period (until 68 years of age). The Western population matures and more and more people represent the third age. These people are still fit and healthy, have generated wealth and experience during their careers and possibly find it too early to retire completely and need something interesting to do. Hence, the third age citizens are also increasingly considered as an important and interesting source for potential entrepreneurs. Not least because the shift in the age profile of the population has major implications for the ability of the state and the corporate sector to continue to pay pensions to retiring employees. (Blackburn – Hart 2004) Based on our study, however, the third agers do not seem motivated by the entrepreneurial career but on the contrary they perceive the option less desirable and are less likely to set up a business in the near future than the persons in the other age categories. This might reflect also the policy development where the youth entrepreneurship has been on the agenda for many years but the idea of the third-age entrepreneurship is a new-comer. Hence, more emphasis should be placed on promoting entrepreneurship, for example, part-time entrepreneurship for the third-age people. In this way, they could more flexibly integrate free time and work-life.

As expected the role of entrepreneurial role models in the family (parents, sisters and brothers) increases the likelihood for setting up the firm. Interestingly, however, the role models do not have an effect on all of the dependent variables. For example, the parents as entrepreneurs increase the intent and the feasibility of the entrepreneurial career but not the personal desirability. This might result that the entrepreneurial are not only positive: If the parents have had limited amount of free-time and not enough time and energy for the family, this might be decrease the desirability of the career although it is considered personally feasible. Especially the role of the spouse is underlined in the study: the spouse as an entrepreneur more than doubles the

perceived personal desirability, feasibility and intent to set up the firm. On one hand this makes sense as the respondent is able to consider that if her or his spouse is doing well as an entrepreneur and enjoying the life, why could not she or he as well? The positive attitudes might also be connected to the intent of joining the spouse's firm later on. On the other hand, we could have expected also a contrary result from the study. The respondents might consider the risks of dual-entrepreneur households and be less likely to start up the firm than the persons with spouses in wage-work. In general, the other family members (parents, sisters etc.) do no longer live in the same household so the economic consequences of their failures do not affect the respondents. In this sense, this is an interesting finding from our study. This is also an area that is rarely discussed in the media or in the policies. Based on our study it might be interesting to provide entrepreneurship training courses directed to the spouses of entrepreneurs.

It also seems that the university study background effects the entrepreneurial intent: The students or graduates with an engineering background are less likely to set up a firm compared to students/graduates with a background in management or natural sciences. Management studies also increase the likelihood for the perceived feasibility. In order to promote the birth of new technology-based firms it might be an interesting option to promote entrepreneurship more heavily for the engineering students and graduates. For example, forming inter-disciplinary teams in the university might help to develop teams with both the technological and business knowledge.

With regard to the future of entrepreneurship in Finland, it seems promising that the students in the study find entrepreneurship more desirable as a personal career alternative than people participating already the working life. The students also consider it to be a generally desirable and feasible career option for other people which might increase their willingness to promote the alternative for other people (friends, relatives). However, they might need further training and skills to increase their perceived personal feasibility and actual behaviour. It is important not to lose this positive attitude over the years at paid work. Hence, it is important the universities and professional associations develop entrepreneurship awareness raising campaigns and training also for the people already at work, not just for students.

**ABSTRACT**

An exploratory study was conducted to investigate the experience of widows who succeeded their deceased spouse in a privately-held business. The purpose of this study was to identify factors which affect the business performance when the widow is at the helm of the company. There is no previous research on women in this role.

Using qualitative methods, this study describes the experiences of 16 widows who took over their deceased spouse's business. In each case, the husband died unexpectedly and the woman was left with the decision to continue the family business. The organization's performance before and after the takeover, and factors affecting the business's performance when the widow succeeded her husband as leader are investigated.

Performance increased in 14 out of the 16 organizations after the widow took over the company, one had no change, and one had a slight (2.75%) decrease. The increases in average annual sales ranged from 3.13% to 225% with an average of 44.2% . To explain the results, the study describes several characteristics of the women in the sample. Number of years of widowhood, age, and financial knowledge were among the variables investigated in relation to performance. The study concludes by offering recommendations for future research. While this study does not provide causality, it suggests important facts and relationships to provide assistance for all business owners and their families.

## INTRODUCTION

Sixty to 70 percent of U.S. Small businesses define themselves as family owned, according to recent surveys by Arthur Andersen Enterprise Group and National Small Business United. Nearly 40 percent of small-business owners hire a spouse, while 37 percent have their children on the payroll. Family businesses are the backbone of the American economy, making up more than 90 percent of over 15 million businesses. Most are small to mid-sized, but they range throughout the business spectrum. Even among the Fortune 500, more than one third are family controlled.

Statistics indicate that, following War World II, the formation of small businesses was on the increase. Now, forty years later, there is an emerging problem in the leadership of these businesses. The predominately male owners are approaching retirement age, and most have not planned for leadership succession. This may be for a variety of reasons. Occasionally, the owner/founder is the roadblock due to his or her anxiety over death. Some act as though death were something that happens to everyone else except themselves. Owners may also fear losing their identity by turning over the company, or they may simply hate losing their power base (Kets de Vries, 1981). In other cases it may be the family that represents the roadblock. Not only can family members be hampered by the death anxiety already mentioned, but they may also suffer from the fear of sibling rivalry or a change in their position or status.

Another reason for the lack of succession planning is that the owner usually is the business. In the field of entrepreneurship, researchers have argued that the firm becomes an extension of the founder's self and plays an integral role in forming his or her sense of identity (Kets de Vries, 1981). The individual's personality and talent make the business what it is. If the owner was removed from the picture, the business might be unable to continue. Additionally, this individual may not want to be removed. So, if the owner begins to have health problems or is unable to manage effectively, the individual may still hang on to the business. Furthermore, entrepreneurs often are unable to find someone with their talents. Potential successors lack the creativity and innovativeness of the founder and this can be particularly important (cf. Kuratko & Hodgetts, 1989).

Additionally, there is the common problem of considering one's children to be too young to take over, regardless of their chronological age. If a father brings up succession planning, his wife thinks he's suffering chest pains. If the children bring it up, both parents may think they're greedy.

Family management succession poses one of the greatest challenges for these business owners. This undoubtedly helps account for the fact that only one third of all enterprises prosper through a second generation and only one tenth through the third generation. Upon initial examination, succession does not seem as if it should be a major problem. All the owners have to do is designate which heirs will inherit the operation or, better yet, train one (or more) of them to take over the business during the founders' lifetime (Kuratko & Hodgetts 1989). However, in reality, one problem that most family businesses experience is planning how to pass control of the

business onto that next generation.

In fact, most family-owned businesses never even formulate succession plans. Transferring management/ownership of a family business is always difficult and often emotional; it affects family members, bankers, employees, managers, competitors, lawyers, spouses, and friends. The only sure thing is that failing to plan will make a transfer more difficult and painful.

Traditionally, the wife of the family-business owner stayed home and raised the children while he dedicated his life to building the business. Although the business had a profound influence on her life, all too often the traditional wife knew little about it. Given that men statistically have shorter life spans than women, these men often die before their wives, and the leadership and management-succession roles are left to his wife by default. If the owner died unexpectedly, his widow often found herself unprepared for the responsibility of a business that had lost one of its most valuable assets: its leader. Sometimes, by necessity, she stepped into the business and assumed control (Benson, Crego & Drucker, 1990).

When a widow finds herself with the unanticipated dilemma of suddenly owning her spouse's business when her husband dies unexpectedly, there is often a lack of guidance for her. The widow is faced with the responsibility of selling the business, operating the business, or hiring someone to run it. Sometimes, the widow has never worked in the business or, if she has, it has not been within a leadership position.

The literature on women in family business is still gestating. Serious papers on the subject total 5 or fewer (Gersick & Salganicoff, 1990). This is an exploratory study undertaken to investigate the frequent crisis situation which occurs when a widow succeeds her husband as leader of his business. The purpose of this study is to examine the business's performance at the time of the husband's death compared to when the widow is at the helm of the company. The need for studying this group is based, in part, on the increasing number of women who are experiencing this situation. However, no specific literature has been found which focuses on the widow's role in the business after her husband's death (McKinley, 1984). Therefore, there is a need for more research on the effects this situation has on the widowed woman and her family.

## **METHODOLOGY**

Most studies of family-owned businesses have focused on the male entrepreneur or on his wife (McKinley, 1984). A case study method of descriptive research, which is exploratory in nature, was chosen as the appropriate methodology for this study of an aspect of family-owned business. Fowlkes (1980), describing her research on wives of those in medicine and academe, stated that the advantage of the personal interview as a data-gathering technique is that it can *combine* structure and standardization with open-endedness and flexibility. The case study is ideal for this purpose as it is an examination of a specific phenomenon (Merriam, 1988) in a bounded population (Marshall & Rossman, 1989). Utilizing this approach then allows the researcher to focus particularly on the phenomenon of interest, obtain rich descriptions of the phenomena, illuminate our understanding of the phenomenon, and draw general inferences from the specific

subjects. In using this method, the desire is to generate findings that indicate an in-depth understanding of the management performance of the widows while providing breadth in terms of research implications for future studies.

Prospective subjects were identified through networking (friends recruiting subjects who are not known by the interviewer), insurance agents, accountants, attorneys and other professional advisors. In addition, referrals were supplied through the U.S. Small Business Administration, the Service Corps of Retired Executives (SCORE), Small Business Development Center at the University of Pittsburgh, Internet Government Census, and the Family Firm Institute. Eighteen widows were identified who met the following criteria: a widow who has taken over the leadership of her husband's business as a result of his death; between thirty-five and eighty-five years of age; business (formerly her husband's) had a sales volume of \$1 million when she assumed leadership of it; business is located within the mid-Atlantic region of the U.S.

The first criterion was developed to directly address the research population. The second criterion allows a broad enough age group to span the experience of several generations. The third criterion was included because it deals with the increased number of problems in a larger volume business. Finally, the fourth criterion restricting location was included so that the subjects would be within an area easily accessible to the researchers. Of 18 subjects contacted, 16 agreed to participate, and the 2 subjects who declined did not offer a reason for their refusals.

Before the interviewing process, subjects were informed of the full intent and requirements for the study. Confidentiality was assured through elimination of identifying data, and a written release of information, including permission to use direct quotes, was signed by each subject before interviewing.

In-depth descriptions of the experiences, along with biographical and business data, of the 16 widows who have succeeded their deceased spouses in business were collected. The interviews were tape recorded and transcribed for the purpose of content analysis. A pilot study was conducted to familiarize the researcher with the sample, the procedure, and to refine the instruments of research and analysis procedure for this study. As a result of the responses to questions in the first interview, the questions were redesigned to elicit greater depth in the subjects' answers. After completion of the interviews, the audio tapes were transcribed verbatim. The data were then analyzed.

In literature, business performance is usually measured from the economic perspectives of growth in sales or employees and by the increase in profits (Barr, Box, & White, 1993; Chandler & Hank, 1994; Covin & Covin, 1990;). Women-owned businesses tend to be smaller and slower to grow, and they often appear less successful if measured by economic criteria. Gattaker and Larwood (1989) suggest that women may seek outcomes other than business growth as measures of their success. Women have a stronger preference for businesses which offer opportunities that are more closely related to personal satisfaction, like professional growth and challenge, while men prefer businesses that offer higher sales and income (Bigoness, 1988; Buttner & Moore,

1997). Therefore, in this study, management performance was measured by change in annual sales and satisfaction of each woman in her new role.

## RESULTS

Of the sixteen subjects who participated in this study, five of their husbands had a succession plan in place at the time of his death. These five subjects were all operating second-generation businesses, and they and their spouses were very knowledgeable concerning the advantages of having a succession plan in place at the time of death. The other 11 subjects were knowledgeable of a succession plan and had previously discussed the concept, but for various reasons a plan was not put in place.

At the time of the husband's death, the sales in the companies examined ranged from \$500K to almost \$50 million. The time since the husband's death ranged from less than one year to approximately 30 years with an average lapse of 12.63 years. Although all of the subjects were lacking in the knowledge of finance prior to their husbands' deaths, of the sixteen organizations studied, sales performance since widowhood increased in fourteen, decreased (2.75%) in one, and had no change in one. Sales performance increases ranged from 3.13% to 225% with an average increase of 44.18%. Total increases in sales ranged from 30% to over 1000% (see Table 1).

=====  
TABLE 1 ABOUT HERE  
=====

The youngest subject was widowed at the age of forty and the oldest at 68 with an average age at widowhood of fifty two. All sixteen subjects graduated from high school and several took additional business courses. Two had Bachelor's Degrees, two had Masters Degrees, one had a Ph.D., and one had a Nursing Degree. In the number of years the subjects were widows in relation to the average annual increase of sales, the average annual percentage increase in 1-to-10 years of widowhood (n=6) was 78.5%. In the 10-to-20 year category (n=6), the average percentage increase was 8.16 percent and in the 20-to-30 year category (n=4), the average percentage increase was 23.99 percent (see Table 2).

=====  
TABLE 2 ABOUT HERE  
=====

When comparing the widows' ages with their companies' average annual increase in sales, more interesting patterns emerged. The group of those widows in their 60s had an average increase of 75.02 percent, which may be accounted for by the fact that this group also has the businesses with the longest periods of operation ( $\bar{x}$ =54.5 years, run by the widow an average of 15.17 years). In the 70s age group, there was an annual average increase of 23.13 percent, and the lowest

average increase was shown in the 50s age group with 9.99 percent (see Table 2).

### DISCUSSION

The purpose of this study was to explore the effect on business performance when a widow succeeds her husband as president of a privately-held firm. This is significant because women often have to take over the family business upon a husband's death and there is little guidance for women in this situation.

All but two of the businesses demonstrated an increase in sales when taken over by the widow. It appears that the first 10 years of widowhood produced the greatest amount of annual sales increases. That the greatest increases were shown during the 1-to-10 year period might be because the subjects were more energetic and enthusiastic during this initial period than later. It could be because they were younger, had younger children, and needed more income. They also could have been more knowledgeable. In this category, the subjects had more formal education: one subject held a Ph.D., one held a Master's degree, two held Bachelors' degrees, and two had high school diplomas.

The highest increase in sales in the 60s age group could be attributed to the fact that the children who are presently in the business are college educated and have more skill in marketing than those in the first generation. Since the takeover, 14 of the subjects described an annual increase in sales and profit. Several have moved to new locations that were on the drawing board at the time of the takeover, and several planned these new locations on their own. Only one subject did not have an increase in sales since the takeover, although she has added a new division to the business. She attributes this to the economy and several other factors. This subject also stated that her husband was a great risk take while she is not. This could be one of the reasons for the decrease in sales.

This research provided answers to questions but also revealed new ideas for further investigation. While the results are very strong, more research is necessary to obtain results that are statistically significant. Today, women-owned businesses are no longer a new phenomenon, and an increasing number of women have become business owners by default when the husband has died unexpectedly. Before 1970, women owned only 5 percent of all U.S. businesses, but currently they own approximately 30 percent. These women entrepreneurs have changed history by undertaking great risk, facing great personal difficulties, legal barriers, discrimination, ridicule, and danger in order to pursue their dreams.

Further research is necessary to reveal how the husband's and wife's management style affect

organizational performance. Are these organizations more successful because the women take on nurturing and caring management styles? Is this true internationally? Also, the sample in this study was restricted by age. Future research should broaden the age groups investigated to reveal whether the age of the woman or even the ages of her children affect the success of the organization. It is possible that younger women with younger children are even more driven to make these companies succeed in order to support their families. Finally, the success of widows should be compared to the success of men who find themselves in the same situation, and to other women entrepreneurs. Although more rare, comparing widows and widowers might reveal that anyone who takes over a spouse's business is driven to make that company succeed, perhaps out of love for the one who was lost, or just plain determination to make the company a success in memory of the lost spouse.

**ABSTRACT**

This paper attempts to study the effect of parental work profile on the career paths taken by their offsprings. The study brings to light the various determinants of choice based on parental work profile which can help us comprehend the basis on which entrepreneurship can be promoted in developing countries. Also, it will help an aspiring entrepreneur realize and evaluate his resources and thus decide the course of his career.

Entrepreneurship exhibits innovation as well as acts as a major new job creator in an economy, with cost-effective strategies for economic development. Through our knowledge-based perspective we perceive it to possess the capacity to boost the economy in developing nations.

The choice-theoretic framework of the study focuses on determination of the factors that lead to different career choices for the offsprings depending on their parents' work profile. In developing countries like India, the economic and societal environment makes the involvement of parents in the lives of their offsprings inevitable.

Through a survey, we have analyzed the plausible parental factors that influence the career choice of offsprings: (a) emotional support of parents towards the chosen career choice, (b) job satisfaction of parents about their work profile, (c) job satisfaction of parents about their

earnings/perks, (d) available financial support from parents, (e) networking of parents, (f) professional guidance available from parents in the chosen career choice.

## INTRODUCTION

---

In a developing country like India, the economic and societal environment makes the involvement of parents in the lives of their offspring inevitable. This paper attempts to comprehend the manner in which the parental work profile influences the career path taken by an offspring.

Entrepreneurship is commonly defined as the pursuit of opportunity, whether for a profit or non-profit venture, without relying exclusively on resources currently in one's control. That is, entrepreneurs see opportunities, often where others only see obstacles, and they pursue these opportunities by finding ways to mobilize needed resources (Melissa A. Taylor, 1997). Entrepreneurship therefore has the capacity to become the driving force in any economy. It exhibits innovation as well as acts as a major new job creator in an economy with cost-effective strategies for economic development.

In India, there has been substantial growth in the higher educational system and it generates over 3 million graduates every year. However, the employment generation system is not in a position to absorb the graduates passing out from the universities, leading to an increase in educated unemployed, year after year. India envisions to be developed by the year 2020 and factors like these necessitate the promotion of entrepreneurship in India.

The path to entrepreneurship taken by a person depends on numerous factors. These factors range from something as localized as personal conditions to something as large as the global economy. Some of these factors are direct and can be studied in terms of monetary indicators. However, other factors, which at times are more influential than the economic factors are environmental factors. These environmental factors govern the will that goes behind making a successful entrepreneur.

The study concentrates on the career decisions of the students from the engineering discipline which involves a large fraction of students. India significantly differs from the developed countries in terms of the influence parents exert on the career choices of their offsprings. The effect of parents on a child has innumerable dimensions. Factors like parents' educational profile, work profile and experiences exert a crucial and sustained influence on the children during the forming years of their lives. India's societal norms accord primacy to attributes such as a steady and stable individual career path, reduction in the levels of uncertainty and ambiguity, an aversion to failure, and the desire to 'fit' within a certain 'mould'. This leads to weaning away the youth from entrepreneurship. Also, there is immense financial dependence of children on their parents since India, being a developing economy, still has a long way to go in providing funding and support to nurture entrepreneurs.

A wrong career decision often shelters many other problems which emerge with the progress of time. Activities like job dissatisfaction, reduced efficiency, job hopping and other psychological problems come as by products of the faulty decision.

Realizing the importance of entrepreneurship in India's developing economy, this paper attempts to determine and weigh the plausible factors based on parental work profile that influence the career path of the offspring. Such an analysis will help the policy makers encourage entrepreneurship, and also help people in evaluating their career options on the basis of the analysis.

## LITERATURE REVIEW

---

In an attempt to realize the various parental work factors that influence the career decisions of the offsprings, we began the study by analyzing the previous research done in this sphere. Much research has been done to examine the influence that parents exert on their offsprings' career decisions. However, almost none was specific to the work profile of parents.

Research indicates that parents have an important influence, perhaps the single most important influence, on the career and job choices their children make (Kotrlík & Harrison, 1989; McCracken & Odell, 1988; Otto & Call, 1985; Splete & Freeman George, 1985). The major family determinants of children's career development can be categorized as follows: geographic location, genetic inheritance, family background, socio-economic status, family composition, parenting style and parental attitudes toward work (Splete & Freeman-George, 1985). Authorities in psychology and career development believe that parents are the most crucial factor in the formation of children's personalities and self-concept, and that career choices can be regarded as the "implementation" of these qualities (McDaniels & Hummel, 1984). As children make self-assessments and receive feedback from significant others, they form educational aspirations. These in turn are a primary influence on educational achievement, the level of which is the single most important determinant of eventual occupational achievement (Otto, 1984).

However, research also indicates that to be effective in vocational guidance, parents need knowledge of career paths and development (Schergens, 1980). Schergens separates the role from the parents in two shutters: that of guide (nobody-resource) and that of provider of information and experiments for the child. In other words, the parents must assist the child by developing on their premises good attitudes vis-à-vis with work (respect, direction of the responsibilities, motivation, etc).

Although parents have the most vital influence on the youth, they may be restrained by factors beyond their control such as culture and economics. Middleton and Loughead, in 1993, presented three categories to describe types of parental involvement in adolescents' career development: (1) positive involvement, (2) non-involvement, and (3) negative involvement. The greatest anxiety adolescents feel about their career decisions or exploration, quite understandably, is in response to parents' negative involvement. Parents in the "negative involvement" category are often controlling and domineering in their interactions with their children. The children of such parents often pursue the careers selected by their parents rather than those they desire so as not to disappoint their parents or go against their wishes (Middleton and Loughead, 1993).

One family variable that has been shown to influence career aspirations includes the parents' occupation (Trice, 1991). The father's occupational status is highly correlated with his son's occupation (Blau, 1992; Blau and Duncan, 1967; Conroy, 1997).

## THEORY CHOICES

---

### Figure 1

Using our knowledge-based perspective, we realized that the following factors (see figure 1) are crucial in influencing the career paths of the offspring: emotional and financial support available from parents in the chosen career path, professional guidance available from parents in the chosen career path, job satisfaction of parents in their jobs as well as in terms of their earnings/perks, and the networking of parents.

## METHODOLOGY

---

### Data Collection

Since we were interested in studying the effects of work profile of parents on the career choices of their offsprings, it became vital to select students who had enough knowledge and awareness about different possible career options ahead of them as well as the Indian economic scenario. Thus, we went ahead to study the students pursuing engineering in one of India's finest engineering institute – the Indian Institute of Technology Delhi ( IIT Delhi). IIT Delhi has had a tradition of making successful entrepreneurs as well as employees who have gained prestige and power in all corners of the world. The atmosphere in this institute promotes an overall and sound development of students. Since IIT Delhi has students from all sections of the society and all parts of the country pursuing their engineering here, the sample has a wide database. IIT Delhi offers different types of courses at the undergraduate level. We have sampled students pursuing their Bachelor of Technology (B.Tech) degree in different fields of engineering. The survey was conducted on 200 students.

The study included the following steps:

- (1) Developing the choice-theoretic model (figure 1) that correlates the various factors based on parental work profiles that influence the choice of an entrepreneurial or non-entrepreneurial career for the offsprings
- (2) Completion of the survey of students through a structured questionnaire
- (3) Data analysis using analytical techniques and interpretation
- (4) Testing and validating the hypothesis of the model
- (5) Deriving the implications of the model

A structured questionnaire was prepared that was distributed amongst the sample and explained to them. To gather more information about the reason for their responses, some of the sample was also spoken to in person.

### Variables

The different career options for students based on our understanding of the trends being followed in IIT over the last decade were found to be (1) Low Scale Entrepreneurship, (2) Medium Scale Entrepreneurship, (3) High Scale Entrepreneurship and (4) Service/Salaried Job.

The factors depending on parental work profile that were assumed and later verified to be affecting the career choices of an offspring were:

- 1) Need for financial support from parents
- 2) Need for emotional support from parents
- 3) Need for networking of parents
- 4) Need for professional guidance available from parents
- 5) Job satisfaction of parents about their work profile
- 6) Job satisfaction of parents about their earnings/perks.

---

## **RESULTS AND DISCUSSIONS**

---

---

Table 1, Figure 2, Figure 3, Figure 4, Figure 5

---

Table 1 shows the relative effect of factors (on a 10 point scale) regarding parental work profile that affect the career choice of the offspring. Figures 2, 3 and 4 show the relation between parental work profile and the various career choices of a student.

Results show that the need for financial support from parents is minimum for a salaried job and maximum for high scale entrepreneurship. Finance is a major milestone that needs to be crossed to start a business venture. Thus financial support from parents becomes crucial. This clearly shows that due to lack of enough finance, a lot of students are made to take up a salaried job for some time and after earning for some years and after gaining enough financial backing, they switch to entrepreneurship. This not only adds to dissatisfaction in one's jobs but also makes them lose precious years of their youth in an occupation they don't desire.

Results indicate that the need for emotional support is minimum for a salaried job and maximum for high scale entrepreneurship. This need was found to be more dominant than money because of the fact that Indian parents are deeply involved in the upbringing of their child. They often guide their child into taking a particular career choice, often influenced by their expectations from them. Children also wish to live up to the expectations of their parents and their career choices are thus dependent on the emotional support that their parents provide them within their careers.

As shown by results the need for networking is minimum for a salaried job and maximum for high scale entrepreneurship. Networking is extremely benefiting in an entrepreneurial career.. Thus students expect enough help in terms of the contacts that their parents have made in their working life. Lack of this, as the results show, make a student feel discouraged for entrepreneurship and he/she thus prefers to go in for a salaried job which requires minimal networking from parents.

Need for professional guidance was found to be minimum for a salaried job and maximum for high scale entrepreneurship. Professional guidance from parents is an important factor in choosing an entrepreneurial career. Any crucial decision is based on a lot of advice. And since again, the environment in India makes the parental involvement inevitable, offsprings have a natural inclination to look up to their parents for guidance. Service/salaried job on the other hand requires much less professional guidance from the parents.

The response of parents towards their job in terms of work profile, salary and perks is often the key to what the offsprings perceive and how they weigh that career as an option for themselves. Also, a parent dissatisfied with his/her job will try and persuade the offspring not to go for the same career. Similarly a satisfied parent will persuade his/her child for the same occupation.

### **IMPLICATIONS OF THE STUDY**

---

The results indicate that the effect of need for financial support from parents, need for emotional support from parents, need for networking of parents and need for professional guidance available from parents increase as one moved from salaried job to low entrepreneurship to medium entrepreneurship to high entrepreneurship as a career option. Thus due to lack of financial support, emotional support, networking of parents and professional guidance from parents, a large percentage of country's youth is inclined to go into options other than entrepreneurship (service/ salaried job). Such a practice has many disadvantages which tend to emerge over a period of time. It decreases the offsprings' productivity in the company where he/she is reluctantly employed; it results in job hopping and many other such problems.

Considering all this, it becomes essential that we frame policies that help and assist students in overcoming the negative effect exerted by lack of enough support for entrepreneurship from their parents. These policies could be in terms of entrepreneurship awareness camps for students as well as for parents that would help parents realize the positives of entrepreneurship so as to help and encourage their children in going for the same. Policies could be in terms of improving financial support in terms of banking and other financial benefits for entrepreneurs. These policies would promote entrepreneurship and speed up the process of economic development in the country.

The study would also make students realize that the effect that is exerted on them by their parents consciously or unconsciously, is to be taken into account and only after considerations of all such factors should a right career be chosen. This would lead to greater job satisfaction for the student as well as satisfaction for the parents.

The study, although conducted on engineering students of IIT Delhi, has a lot of attributes which are common to many developing countries which see a large involvement of parents in their offsprings' life. Such a study opens the doors to extensive research that is required in this field to point out the ways in which parents influence the career choices of their children. This is essential since without this, attempts to promote entrepreneurship will not be as successful as they can be.

A similar study also needs to be done for students who do not have bright career options, as our sample. This is essential as in a country like India, employment is difficult to find. A study on them would help present a deeper analysis of this issue.

Email: [jjeynes@opalserve.fsnet.co.uk](mailto:jjeynes@opalserve.fsnet.co.uk)

### **Abstract**

The last decade has seen significant changes in the business environment for small firms and individual entrepreneurs. This paper considers the business environment for women in 1995, based on findings of a large-scale survey for the 4<sup>th</sup> UN conference on Women held in Beijing, and key issues facing them at that time.

The 50th ICSB World Conference provides a “golden opportunity” to revisit the original survey and consider whether conditions for women running their own businesses have changed significantly since then. The original survey questions are used as the basis for a follow-on survey (2005), with some amendments/additions to broaden the scope, in order to identify practical concerns of women in business, whether these have changed significantly, and their views on further changes that are needed.

Where possible, respondents from Survey 1 will complete Survey 2, to identify areas of change since 1995. In addition, new groups of respondents will take part in the survey to give a broader base of knowledge and to reflect a greater social/ cultural/ ethnic/ demographic mix.

Initial responses to survey 2 will be analysed, with on-going distribution and analysis of survey questionnaires during 2005 to continue the research on a larger scale. Clearly this is a major piece of research work that is only partly completed, and results from the first group of respondents will be analysed and presented to delegates at Conference in Washington DC in June 2005.

### **Introduction**

At the United Nations 4<sup>th</sup> World Conference on Women, held in Beijing ten years ago, the author presented a paper that considered the contribution of women entrepreneurs to the world economy[1]. This was based on findings from a comprehensive survey of over 2000 women entrepreneurs in the UK that considered problems and issues they faced when setting up or running their own business[App 1].

The number of women entrepreneurs has risen throughout the last decade, and this 50th ICSB World Conference does indeed provide a “golden opportunity” to revisit the original survey and consider whether conditions for women running their own businesses have changed significantly.

This paper considers the business environment for women in 1995, the findings of the original survey [2], and key issues affecting women entrepreneurs then and now. The original survey questions are used as the basis for the current survey (2005) with some amendments/additions to broaden the scope [App2].

Clearly this is a major piece of research work that is only partly completed, and results from the first group of respondents will be analysed and presented to delegates at Conference in Washington DC in June 2005.

### **The business environment a decade ago**

The picture for entrepreneurs in the UK in 1995 was one of growing awareness of the impact of small firms on the economy generally, and the contribution of women entrepreneurs in particular.

Around 90% of firms in the private sector employed fewer than 50 people with the majority of workers in large, public-sector organisations. Small firms were defined as those with “up to 250 employees”, although this was considered by many commentators at the time to be inappropriate given the type of organisational structure required to support so many staff. The later EU definition of a micro firm employing up to 10 people and a small firm up to 50, reflects a more realistic picture of organisational structures at this level.

Rates for business failures within the first 18 months of trading were around 2/3 with approximately 30% of businesses being started by women [2]. The use of computers and hi-tech equipment was very limited at the time, with many service-sector businesses still operating in traditional ways to serve their customers.

The Federation of Small Businesses (FSB) was the largest small firms representative group in the UK, established in 1975 and growing rapidly to around 70,000 members by 1995. The breakdown of membership was primarily 50% employing up to 10-15 people - 35% as self-employed individuals - 15% employing up to 50 people.

### **The business environment for Women Entrepreneurs a decade ago**

Several preparatory meetings were held around the world prior to the UN conference in Beijing in order to identify issues and concerns facing women, whether in a social, personal or business context. At the preparatory conference in Amsterdam [3], the author presented a paper that identified the following issues for women entrepreneurs:

- the contribution of women to the economy is largely ignored or undervalued unless related directly to paid employment;
- there had been some recognition of the value of work in the home, but as a nominal value if you had to pay someone else to carry out these tasks rather than a contribution to the economy generally;
- women were more likely to work in the voluntary sector, again with their contribution recognised as a value to the individual organisation rather than the national economy;
- there were problems associated with recognising work of equal value/ equal pay with that of men;
- women themselves often saw their contribution in a negative way;
- self-employment should be seen as an “equivalent” option for employment rather than as a last resort;
- self-employment can provide flexibility to combine with family and domestic responsibilities, although that often just means more workload during a day.

At the time, there were many barriers to self-employment identified, including:

- working for yourself often viewed more negatively than working for a large employer; work often seen as a social value rather than a financial one;
- many self-employed women are not working full-time or do not register with the relevant authorities so do not necessarily appear in national data as “economically active”;
- there is little or no recognition of the wide range of management and organisational skills women already possess in a different context from work;
- training programmes need to focus on recognising and transferring existing skills; other groups such as funding or government bodies also need to recognise these transferable skills;
- access to relevant training – better programmes available at the time were usually time-consuming and expensive, and not easy to define in “outcome” terms. They were therefore more likely to be government or EU funded so not equally available to all;
- attitudes of family and others are important – without family support it can be extremely difficult to establish a business (though not impossible of course);
- access to funds – banks at this time agreed that women were more likely to produce better business plans/ succeed once business started/ be better payers of loans than men BUT often had to provide more collateral/ were more likely to be refused funding/ given lower sums than asked for;
- trading activity is often flexible or intermittent so “profit” not necessarily the best measure of “success”;
- the value to the economy may be in diversity of product or service for customers, and the income generated reduces dependence on the state or family.

At the UN World Conference in Beijing, feedback from representatives from around the world suggested that these problems were similar for women wherever they lived. The incidence of entrepreneurship broadly reflected economic recession and levels of poverty, with businesses primarily in the informal and/or service sectors.

Common issues identified were:

- barriers to success as noted above, including attitudes of others and cultural factors, need to be addressed;
- there needs to be better access to relevant, affordable training in skill areas that will support the business;
- the value of women’s entrepreneurial activity for the local economy must be recognised; better measures are needed to reflect their contribution;
- there needs to be better access to smaller amounts of funding, credit, other financial support specifically targeted at women entrepreneurs.

These issues were reflected consistently in research on women entrepreneurs during the last decade, whether by banks directly [4] or by organisations representing the concerns of women [5;6].

However, there have been changes during the last decade for all small businesses, including those established by women entrepreneurs.

- Financial institutions have made significant steps to try and redress the balance of unfair access to funds.
- Self-employment is more likely to be seen as a realistic option for those with family or other responsibilities who want more flexible working choices.

- Access to IT and communication facilities has grown substantially around the world reducing barriers to entry for small businesses to wider production options.

Self-employment is a real option for many women to gain financial independence and, just as importantly, to gain access to decision-makers through networking. It would be encouraging to think that substantial changes have been made to the business environment for women entrepreneurs since the global commitment of governments in Beijing 10 years ago. Anecdotal evidence suggests that these changes may not be as broad as we would have hoped, so this paper provides an opportunity to revisit original concerns and consider the extent to which they have been met.

## **The 1995 Survey of FSB Women Members**

### **Methodology:**

To avoid bias, 11,000 women members of the FSB were sent a comprehensive questionnaire by mail, with a covering letter explaining its purpose and the importance of the results to our UK representation in Beijing. The survey was supported by Lloyds Bank (now Lloyds TSB) and FSB funds through the national Policy Committee. [Appendix 1: survey one questions]

More than 2000 responses were received, 18%, which exceeded expectations. Given the volume of responses, the bank at the time was only able to carry out a raw data analysis of findings [2]. However, this still yielded a comprehensive picture of issues and concerns facing women members at that time.

### **Summary of findings:**

#### **Profile of respondents:**

- 86% were married
- 45% were aged 41-50
- 80% were based in England; 14% Scotland; 6% Wales

#### **Business details:**

- 34% were service sector; 27% retail & catering; 11% manufacturing
- 3% agriculture; 3% transport; 4% construction;
- 28% business had been running for less than 5 years; 21% more than 20 years
- 60% had fewer than 5 employees.

#### **Difficulties experienced as a woman in business:**

- 22% said they believed they experienced difficulties as a direct result of being a woman, mainly related to juggling home and family;
- difficulties included not being taken seriously, customers or others preferring to deal with a man rather than a women, and assumptions that they were the secretary rather than the owner of the business;
- 34% said they had experienced problems at start-up stage and once established. Finance was the most commonly stated problem, 28% saying this related to the amount of funding needed.

#### **Support needed to help overcome problems:**

- 36% gave one or more areas of lack of skills that presented problems for them;

- training was a key issue, with 14% stating time as a problem and 13% cost;
- several respondents referred to lack of provision in their locality, difficulties in finding relevant training courses, and of fitting it in with other responsibilities.
- Cited changes required at macro level included the need to reduce legislative burdens; better provision of childcare and some form of subsidy or tax concessions to reduce the cost of childcare.

### **Conclusions of the survey**

The range of issues identified was diverse with many not specifically gender-related. However, there are clear areas where respondents felt that they experienced additional problems simply because they were women rather than “entrepreneurs”.

Critical questions emerged from this analysis, and the follow-on survey for 2005 will incorporate these. Where possible, respondents from the first survey will be asked to complete Survey 2, to consider whether conditions have changed and if so in what areas. In addition, several new groups of respondents will take part in the survey in order to give a broader base of knowledge and to reflect a greater social/ cultural/ ethnic/ demographic mix.

### **The revised Survey 2005**

Why review now? After 10 years, this would seem to be an ideal time to review progress for women entrepreneurs and to consider whether there have indeed been improvements in the business environment. Banks in particular are keen to suggest that they have made considerable improvements in the way they deal with women business customers, and support bodies such as Business Link/Chamber of Commerce also emphasise their support for women through various networking events.

The last 10 years has seen many EU Directives introduced into national law, some intended to improve conditions for women in the workplace. In particular, the question of work-life balance has been of major concern while technological advancements have provided significant opportunities not previously available to small firms.

### **Survey structure and analysis:**

The majority of questions from the 1995 questionnaire will remain in order to maintain continuity, with additional emphasis on work-life issues [see Appendix 2 for revised questions].

The questionnaire will be distributed to FSB women members in UK, including some who have been members for more than 10 years and who completed the original survey. A hard-copy and an on-line version will be available.

As well as this sector, other groups of women entrepreneurs will be asked to take part, including Business Women’s Forum, Partners for Business clients who have used their business advise & support service, Prince’s Trust, and others in UK and EU countries. An initial analysis of responses will be carried out and results presented at the ICSB 50<sup>th</sup> Conference in Washington DC in June 2005, with on-going distribution and analysis of survey questionnaires during 2005 to continue the research on a larger scale.

## Conclusions

The last 10 years has seen some significant changes in the business environment for small firms and individual entrepreneurs. Clearly this is an ideal opportunity to look more closely at the practical concerns of women in business, whether they feel these have changed significantly, and indeed their own views on further changes that are needed.

### APPENDIX 1:

Survey 1 1995: FSB/Lloyds Bank

#### FSB "WOMEN IN BUSINESS" MEMBERSHIP QUESTIONNAIRE

PLEASE TICK APPROPRIATE BOX

##### 1. FSB Membership Status

Full Member  Joint Member  Associate Member

##### 2. Marital Status

Single  Married  Divorced  Widowed

##### 3. Age

Years

##### 4. Do you have children?

Yes  No

##### 5. If Yes,

How many?  What are their ages?

##### 6. What is your main business activity?

Agriculture  Manufacturing  Transport  Construction   
Wholesale  Retail and Catering  Services  Other

##### 7. Where is your business located?

North  Midlands  East Anglia  South West   
South East  Wales  Scotland  Northern Ireland

##### 8. How long has your business been in operation

Years

##### 9. Number of employees?

Nil 0-5 5-15 15-50 50+

##### 10. Do you operate as:

Sole Trader Partnership Limited Company PLC Co-operative

##### 11. As a woman, are there any aspects of running your business that present difficulties?

##### 12. If yes, please describe briefly:

**13. Have you experienced any difficulties? (Tick as many as possible)**

At start-up stage? Yes No

Once Business established? Yes No

When you want/wanted to expand the business? Yes No

**14. If you answered no to any part of Question 13, was there any person or organisation that was particularly helpful or supportive? If YES, please give brief details**

**15. If you answered YES to any part of Question 13 please identify the area(s) of difficulty, when you experienced them and give brief details:**

**Finance:**

Amounts of Funding

Sources of Funding

Terms and Conditions

Other

**Legislation:**

**Resources:**

Premises

Equipment

Supplies/materials

Other

**Staff:**

Recruiting Staff

Retaining Staff

Other

**Childcare:**

Cost

Availability

Changing need over time

Other

**Attitudes of:**

Customers

Suppliers

Family

Others

**16. Have you experienced any difficulties in the following areas (Please tick which ones and give brief details)**

|                              |                          |                          |
|------------------------------|--------------------------|--------------------------|
| Technical/production skills  | <input type="checkbox"/> | <input type="checkbox"/> |
| Organisation skills          | <input type="checkbox"/> | <input type="checkbox"/> |
| Finding appropriate training | <input type="checkbox"/> | <input type="checkbox"/> |
| Financial skills             | <input type="checkbox"/> | <input type="checkbox"/> |
| Cost of training             | <input type="checkbox"/> | <input type="checkbox"/> |
| Sales/marketing skills       | <input type="checkbox"/> | <input type="checkbox"/> |
| Confidence                   | <input type="checkbox"/> | <input type="checkbox"/> |
| Time involved in training    | <input type="checkbox"/> | <input type="checkbox"/> |
| IT Skills                    | <input type="checkbox"/> | <input type="checkbox"/> |

**17. Are there any changes that could be made at national/international level that would make it easier for you to run your business?**

**18. As we are frequently asked for comments on issues specifically concerning female members, do you think the FSB should have a women's section**

Yes  No

Thank you for completing this questionnaire. You can be assured that your individual comments will be treated in the *strictest confidence*. If you are willing to take part in other surveys related to women in business, please complete your name, address and telephone number below.

PLEASE RETURN TO: JACQUELINE JEYNES, FSB, 140 LOWER MARSH, WESTMINSTER BRIDGE, LONDON SE1  
7AE BY MONDAY 10TH JULY 1995

### **Covering letter to go with Questionnaire:**

Monday 19th June 1995

Dear Member,

I need your help with a major survey the Federation is carrying out on women in business. The survey is being carried out with the help of Lloyds Bank plc. The feedback with your concerns will help when we attend the United Nations 4th World Conference on Women in Beijing in September 1995.

For me to fully represent these concerns, it is vital that you have an opportunity to inform me about them. As there are 15,000 Individual, Joint and Associate women members, it will be too difficult to collate your responses without some sort of structure, so please spare the time to answer the enclosed questionnaire, even if you have experienced no difficulties as a woman in business.

I would be most grateful if the questionnaires could be returned to me, via the FSB, at the above address by Monday 10th July 1995. Thank you for your help.

Yours Faithfully,

Jacqueline Jeynes (Employment Affairs Chairman)

## APPENDIX 2

### Survey 2 2005: Women in Business

Questions follow the same structure as Survey 1 above and cover the following areas (please note this is not the final structure of the actual questionnaire):

1. Omit this as not a major issue with wider set of respondents
2. Marital status and include section for ethnic background
3. Age
4. Do you have children
5. If yes, what are their ages
- 5.a) Do you have any other dependents, if so how many?
6. What is your main business activity
7. Where is your business located
8. How long has the business been in operation
9. Number of employees
10. Legal trading status
11. Have you experienced any difficulties with the business at start-up/ once established/ expanding the business stages? Yes or No
12. Do you believe you have had particular problems as a woman (tick all that apply) sourcing finance/ dealing with customers/ managing staff/ achieving acceptable work-life balance/ sourcing affordable childcare provision?
13. Have you personally faced problems related to – deciding to have children/ organising childcare/ paying for childcare/ maternity cover/ accessing suitable training/ finding suitable premises
14. Has any person or organisation been particularly helpful when starting or running your business? If yes, please give brief details (eg accountant/ bank/ friends etc)
15. As a woman entrepreneur, do you experience problems with attitudes of any of the following – customers/ suppliers/ family/ banks/ others
16. Omit original question 16.
17. Any changes you think should be made at national or international level to make it easier to run your business
18. What business support groups or associations do you belong to – please list.

# COLOMBO, HOLMES, MAIGRET, WILLIAM OF BASKERVILLE AND REGIONAL ENTREPRENEURSHIP

Pierre-André Julien and Richard Lachance

## ABSTRACT

In criminal matters, if, like Colombo, one is able to recognize the direct causes of an isolated crime, when criminality increases in a community, or various forms of gangsterisms occur, this somewhat simple approach proves inadequate. Even the perspicacity of Sherlock Holmes and the intuition of Maigret, are no longer sufficient. We must be able to reflect in the same way as William of Baskerville who “In the Name of the Rose” understood that the crimes committed by the monks of the Melk Monastery were related to a power struggle between the Pope and the Emperor and ultimately to a search for the truth.

Using this metaphor based on the detective novel<sup>1</sup>, in this paper we reassert that regional entrepreneurship cannot be understood by limiting the analysis to the behaviour of a few entrepreneurs and their enterprises, according to a first level approach, however dynamic these may be. In particular, we cannot explain why in many regions which do not have important natural resources or strategic locations, businesses multiply and innovate while in other regions new businesses are few and change sporadic. Then, we must look to the role of the milieu and to the social capital generated by it to facilitate change and opportunity sizing. To this second level, we must analyse rich information and networks which select this information, adapt and transmit it, as well as diffuse innovation to sustain competitiveness or business and regional distinctiveness. Finally, to a third level approach, we must take into account conventions which sustain entrepreneurial culture and then the regional dynamism.

## INTRODUCTION

It is this third level that, firstly, we will try to reach in this communication in order to better understand entrepreneurship, both in theory and in practice, starting from the three most important players of development to get out with the three factors favouring the enterprise and region differentiation and recalling that that entrepreneurship is an eminently collective process. Secondly, we will attempt an initial application of this way of seeing things by studying the very different entrepreneurial dynamism of two small adjacent regions in Quebec (Canada) having the same origins and environments. Finally, in conclusion, we will return to the metaphor of the detective novel, a particularly useful approach to better grasp complexity (Morgan, 1980; Grant and Sick, 1996) by showing in particular how the novels of Conan Doyle or of Simenon apply Marshall's theory, which alone can finally explain the genius of Sherlock Holmes or of Maigret.

### 1. THREE MAIN PLAYERS AND THREE FACTORS WHICH EXPLAIN WHY REGIONAL ENTREPRENEURSHIP IS A COLLECTIVE PROCESS

The first player in entrepreneurship is evidently the *entrepreneur*. To understand it, one must know his antecedents, what some call his inborn, acquired and constructed development (Erickson, 1959). These antecedents include various aptitudes occasioned by his family

environment, by his acquaintances and by the acquisition of knowledge, whether in school or in his contacts with his work environment. It is there that he will find the models that are discussed at the table or at family reunions, or again his work experiences during his free time and which will provide him with various openings to start up and manage his enterprise later. We find in this development three types of influence, positive or negative : the affective, the symbolic, and the sociological, which cannot be other than social, as in the example of even isolated crimes. In this last case, it is fair enough for the lawyer to refer to a difficult family life or again to regrettable associations, hoping the jury will find in them mitigating circumstances favourable to the accused.

The second player is the *organization* (or the enterprise), constituting first of all the extension of the entrepreneur and his capacity to marshal resources, and then the implementation of his effort at appropriating market space. The organization parts from these gradually<sup>2</sup> as the internal and external stakeholders, if not the external proprietors (stockholders), take on more significance. The organization becomes a system of social relations, or even a field of interest, but especially a combination of “rare and inimitable” resources and skills such as interdisciplinary personnel of the enterprise and other complementary resources provided by upstream or downstream firms with which it negotiates and which, by particular combination, ensures its distinctiveness and hence its competitiveness with respect to the market (Barney, 1991; Brown and Eisenhardt, 1998). Evidently, these resources and skills must be systematically upgraded and expanded in order to maintain the organization’s advantages through technological change and through training and information, since technology, the market, and competitiveness are constantly evolving. In the underworld, organization (are we not speaking of *organized crime*?) is a guarantee of coherence and especially of discipline; it is also a management system, often with very complex ramifications that allow for the diversification of sources of revenue and a lessening of detection by the police, if not the buying of protection.

There are all sorts of enterprises. Most are very small and do no more than fill the needs of consumers. Many disappear in their first year and nearly 50% close before their fifth year of existence (Phillips and Kirchhoff, 1989; OECD, 2002a). Only a small fraction, generally fewer than ten percent, referred to as the *gazelles*, grow rapidly; they have a major effect not only on job creation, but on the regional dynamic in requiring the resources and advanced services that in turn act as a stimulant for a good number of other enterprises.

The third actor is the *milieu* which plays a special role in supplying relatively easily, basic resources such as specialized workers, truckers and distributors, financial sources and research centres (Camagni, 1995; Maillat, 1995). The milieu also helps to develop personal, business and information networks with strong or weak ties (Granoveter, 1973) connecting entrepreneurs with lower transaction costs to resources, market opportunities and ideas for innovation and technological change. Finally, the milieu supplies information which serves to reduce uncertainty, risks and the informational ambiguity which limits the entrepreneurial commitment, as well as information which increases the collective learning process and stimulates the innovative activity of firms, mainly that of *gazelles*. As in detective stories the underworld<sup>3</sup> gives coherence and orientation and supplies resources to diversify black-market income sources and to elude the police.

The milieu generates the social capital which facilitates the acquisition of resources such as angel capital but also trust, reputation, and cooperation all of which accelerate transactions and synergy elements thus increasing creation and innovation (Lin, 1999). Social capital develops explicit and implicit rules for legal, political and economic systems, norms and conventions and even ideology thus stimulating the regional dynamism or the entrepreneurial culture, creating what North (1990) calls the informal or the contrary to formal institutions. On the other hand it can also be a system of conformism that limits initiatives and dynamism, even forcing better entrepreneurs out of the region. These rules and conventions can be measured in relation to criminality by observing the level of permissiveness or of social delinquency which they limit or facilitate, for example corruption systems which retard entrepreneurship in developing countries.

Of the three factors which help to distinguish and stimulate a region, the first is *rich information* (Daft and Lengel, 1986), e.g. complex, cumulative and more often tacit information (Leonard and Sensiper, 1998), obtained through inter-personal relations which can be transformed into opportunity and innovation. Rich information is the essential element in transforming organizations (Weick, 1979; Choo, 1998). It allow up to stay up to date on change, and even to get ahead of it through innovation.

The second factor is the sharing of information facilitated by *networking*. Networks are like meshed nets formed by a great number of direct and indirect associates more or less close that are relative knowledgeable of the needs of the interlocutor and this make it possible to grasp and retain this rich information, letting pass current information of little or no interest. This information serves not only to know more rapidly and more easily about various resources, but in seizing opportunities before the others (Ucbasaran, *et al.*, 2001). Eisenhardt (1990) explains why, because of the accelerating changes in the economy, one must turn to real-time information (that is, information as it is created), share it with the greatest number of people in the network and in the organization to finally transform it into insight and actions integrated with the other decisions and tactics. A dynamic milieu with strong social capital stimulates the exchange of information through the multiplication and enrichment of its networks (Allen, 1997), particularly if they are linked to other weak-signal networks, often outside the region, and sources of more radical innovation (Julien, *et al.*, 2002).

The third factor is *innovation*, above all if it is diffuse, modifies most of the enterprise's value chain and it's products thus helping to distinguish the business, it affects the external value chain in the production system (commodities and equipment suppliers, sub-contractors, sellers, testing institution, etc.), and finally gives very important comparative advantages (Dyer and Singh, 1998) which sustain the enterprises' and the regions' competitiveness.

## **2. AN APPLICATION TO TWO SMALL REGIONS OF QUÉBEC (CANADA)**

To apply this analysis somewhat, we have selected to two small closely situated regions in Québec Canada (Centre-du-Québec with 220000 inhabitants and Mauricie with 263000) with relatively the same industrial history. Both were in decline from 1960 to 1990 at the end of the second industrial revolution. But in the last decade, the first has renewed faster than the second because the social capital is stronger, the networking is more complex and technological, giving

richer information and thus more innovative firms and finally because the entrepreneurial culture is greater.

An example of the development difference can be seen on Table 1 for the 1990-2001 period. The data show that if the rate of regional creation (when compared to existing enterprises) is greater in the Mauricie than in the Centre-du-Québec, the portion of fast growth SMEs (having at least doubled the number of their employees during this time) is close to twice as great in this last region, i.e., 21% vs. 13%. In particular, the Regional County Municipalities (MRC)<sup>4</sup> of Drummondville, the most important city in the Centre-du-Québec, has 27% of its manufacturing firms experiencing fast growth while its Maurician counterpart, the MRC de Francheville, where we find the most important city of the north region, Trois-Rivières, is made up of but 10% fast growth firms. As we said, the fast growth firms are particularly responsible for job creation (OCDE, 2002b), it is then not surprising that the unemployment rate for the last few years in the Centre-du-Québec has been consistently inferior (on average 8.7% from 2002 to 2004) to the rate in Quebec (9% in general) while just the opposite was true for the Mauricie (10.5%).

---

Table 1 about here

---

Since it is difficult to directly measure the impact of the milieu, and thus of the social capital, on these differences in dynamism, we have limited our study to evaluating the impact of complex networks on the development of manufacturing SMEs having between 5 and 500 employees in a single survey in each of the regions. The survey in the Mauricie region was conducted through the mail, that for the Centre-du-Québec was done by telephone (20 minutes). The questionnaire was made up of 11 questions concerning the entrepreneur's networking activities with some data on the evolution of profits and sales and on exports. In particular, we asked the entrepreneur the number of different persons with whom he had discussed the development of his enterprise during the past six months, their status (client, supplier, friend, consultant, etc.), the average number of hours per week devoted to this networking, and if this effort was profitable for his enterprise, on a scale of little, enough, or a great deal. Moreover, the entrepreneur had to specify if these persons were new to him and if contact with them was maintained. The questionnaire was taken from a study in Sweden (Johannisson, 2000) and was adapted and vetted using ten enterprises to ensure clarity for the respondents.

The enterprise populations of the regions were taken from a financial evaluation company's repertoire of firms. For the Mauricie, we mailed 540 questionnaires to finally received 87 completed. For the Centre-du-Québec, we started with a possibility of 840 manufacturing enterprises to finish with 137 completed questionnaires. As the length of this paper is limited, we cannot show tables of these data. We must say that the samples representativeness is relatively good, particularly for regional repartition. According to size, we notice that the response rate decreased relatively with size in the Centre-du-Québec region while this rate remained fixed in the Mauricie resulting in a more conservative view because the small business networking is generally less developed than larger firms.

Table 2 shows the results of a typological analysis undertaken separately in each region. A typological analysis is a method that seeks to identify types of behaviour within a population. It involves first establishing a classification and then counting the number of matching firms. Or, as

we did, the classification variables can be used in a statistical process (Sharma,1996). We performed a hierarchical typological analysis using SPSS software (Wald's method using Euclidian distances). We retained a three-group classification.

---

Table 2 about here

---

The enterprises of the first group seek information from a variety of sources, both business sources (clients, suppliers, other entrepreneurs and competitors) and sources more informational, generally weak-signal (consultants, industrial associations, financial institutions and government bodies, including colleges and universities). Enterprises in the second group concentrate their search for information on less traditional sources; business people, financial institutions, government bodies, as well as consultants and former colleagues ( in the case of the Centre-du-Québec). Lastly, firms in the third group have no ultimate preference and appear somewhat introverted, seeking little information. A comparison between the two regions gives some advantages to the Mauricie over the Centre-du-Québec; 34% compared to 23% of the firms in this region are in the first group and 32% compared to 21% are in the second.

---

Table 3 about here

---

Table 3, however, brings a nuance to this first result. It shows that the firms in the first two groups from the Centre-du-Québec discuss the development of their enterprises with more people and take greater advantage of these contacts in proportion to “the efforts invested in the maintenance and development of their networks”. Firms in Group 1 export more. Finally, according the study's data, these firms continue to maintain new contacts which contributes to the renewal of their networks thus illustrating informational dynamism. 76% of the enterprises in the Mauricie and 72% of those in the Centre-du-Québec have less than 15% of new contacts among the people with whom they have spoken of development. However, 76% of the firms in the Centre-du-Québec stayed in contact with more than half of their new sources (28% with all their new contacts) while only 48% of the firms in the Mauricie maintained this contact (5% with all).

Another clue can help us understand the difference in regional dynamism. A telephone survey of the regional management of six venture capital firms allowed us to see that angel capital was at least twice as dynamic in the Centre-du-Québec than in the Mauricie to the point where these firms had difficulty financing projects in Drummondville, for example. The entrepreneurs of the Southern region could fairly easily meet their needs with angel capital without having recourse to official capital. Moreover, we have witnessed this capital operating in a particularly effective manner in the first region on several occasions.<sup>5</sup>

In short, the differences between the two regions cannot be understood other than by a different collective entrepreneurship, thus by an “industrial atmosphere” or an “entrepreneurial culture” not having the same dynamism.

## CONCLUSION

This with short applications, because the limited length of this paper, shows that by taking into account the quality of the milieu and the social capital and by introducing rules, norms and conventions or an entrepreneurial culture which stimulate a rich information exchange, we use more than an interpretive approach (Strauss and Corbin, 1998). The values shared in the region generate dynamic complicities or what Alfred Marshall called over one hundred years ago an “industrial atmosphere” particularly innovative for enterprises and regions.

By applying rich information, networking and innovation, we can go further with a constructionist approach to explain how enterprises structure and regional players stimulate change and sustain distinctiveness to create a virtual cycle for development. As in the detective story, we thus reach a third level of explanation as Baskerville does. This is illustrated in table 4.

---

Table 4 about here

---

Thus we demonstrate that entrepreneurship is fundamentally a deep collective phenomenon which cannot be understood without a complex approach similarly to the crime story metaphor in the Umberto Eco novel. It is like Conan Doyle who demonstrates indirectly that the success and the genius of Sherlock Holmes, as a brilliant entrepreneur, cannot be explained without considering the dynamic entrepreneurial atmosphere of England in the late 19th century, an atmosphere which allowed Holmes and his friend, Dr. Watson, after receiving a tearful widow from a distant country, to easily send several telegrams, to place two or three advertisements in newspapers published that very afternoon, to procure two tickets for a train which left on schedule, to hire a good carriage upon arriving at the country station and finally to get a room in a comfortable inn after an excellent meal.

Similarly, seen from a different angle, Maigret explains in his *Mémoires*<sup>6</sup> that in a real investigation officers from the neighbourhood police station, who visit thousands of households, are most often added to his inspectors from the Quai des Orfèvres, who interrogate hundreds of witnesses,. This does not take into account officers in terminals “scrupulously scanning faces,” at times the national police force on the look-out for various clues, and the role of informers and the public who contribute various pieces of information, some of which could be crucial. As Simenon says, these thousands of participants and these hundreds of events could not be described in detail in a novel without confusing the reader. But in the case of the success of an enterprise, we know that it does not depend solely on the entrepreneur, but rather on: the members of its organization, the complementary enterprises upstream and downstream, the information system, and the many players both within and outside the region, not to mention the economic climate and good fortune.

In short, a good detective story is often a pretext for discussing the good and bad sides of people and the quality of the structures and institutions that surround them. Similarly, as with all processes of development, entrepreneurship is quite simply the collective history of people each looking for his own identity, to better know himself and to be recognized for his work (the noble

result of his work through creation and innovation). Entrepreneurship is then a shared experience. For, every individual story or every success or failure of enterprises also belongs to others who endorse it and gives its value or its limits, such as recognition beyond any monetary value for what really constitutes humanity and gives it the power to change things.

**Table 1. Creation of manufacturing enterprises and of fast growth, the Mauricie and the Centre-du-Québec, 1990–2001**

| number of MRC  | Region and MRC          | Existing enterprises in 1990 | Enterprises created* from 1991 to 2001 | Creation rate | % high growth enterprises** from 1990 to 2001 |
|--|-------------------------|------------------------------|--|---------------|---|
|  | <u>Mauricie</u>         | <u>550</u>                   | <u>136</u>                             | <u>24.7%</u>  | <u>13%</u>                                    |
| 35   | Mékinac                 | 48                           | 6                                      | 12.5%         | 21%   |

## ENDNOTES

---

<sup>1</sup> To use as metaphor the most famous detective novels. We could, of course, have used other detectives like those of Agatha Christie with Hercule Poirot, who is somewhat like Sherlock Holmes, or Miss Marple, who is closer to Maigret, or again more contemporary detectives like the Italian Camilleri's Montalbano, the Swede Manke's Walander, or the American Connely's Bosh acting at times like one and at other times like the other.

<sup>2</sup> Except in the case of very small business or of the self-employed.

<sup>3</sup> In French, underworld is translated by the word "milieu", as in "Marseille's milieu", as explained by Maigret.

<sup>4</sup> In general, the Regional County Municipalities (MRC) consolidate all the villages and cities relatively close to one another in a small region with less than 100 000 inhabitants. They were created by the Quebec government to manage services in common and to plan the development of the territory. Their management comes under the authority of a council made up of the mayors and a few counselors in proportion to their population. There are 95 MRCs in Quebec not counting the groupings of the large agglomerations of Montréal, Québec, and Gatineau.

<sup>5</sup> For example, during an advanced formation meeting that our research institute ran, the entrepreneur tenants did few telephone calls to obtain some \$300 000 when they learned that all the elements of a project were in place, such as a product formerly imported by several firms in the region, new and used equipment, space, the presence of a mentor and a young entrepreneur full of promise.

<sup>6</sup> Evidently, according to "An ironic and affectionate confrontation between his *creator* and his character," these words were written by Simenon to explain "the mechanisms of his creation and to condemn the fictional character." In *Simenon. Romans*, vol. II, Paris, Bibliothèque de la Pléiade, 1419-20.

**Market size, market development and investments in human capital in the  
venture capital business: Theory and evidence**

Carola Jungwirth

Keywords: Venture Capital, portfolio management, market size, market  
development, learning, regional differences

## 1. Introduction

Recent studies have shed light on the fact that human capital is a key driver of the investment strategies of venture capital firms: The higher the education degrees of venture capitalists (Bottazzi et al. 2004), and the more industry specific knowledge they own (Jungwirth/Moog 2004, Dimov/Shepherd 2005) the more professional their investment activities seem to be. “Professional” here refers to an early stage/high tech orientation in portfolio management that is often accompanied by a considerable specialization in an industry and/or a financing stage of the venture capital firm. The US venture capital market represents the archetype of a professional approach in portfolio management: The greater part of venture capital managers is assumed to be well educated, to own relevant specific knowledge and to be specialized in one or a few high tech industries and early financing stages (Dotzler 2001, Amit et al. 1998, Norton/Tenenbaum 1993). Pushing the US economy’s high tech sector considerably, the US is the measure of all other venture capital markets. However, it is unique and – like the US market for higher education – hardly to top. The long experience with venture capital, the pension funds system, the well working capital market, the considerable pool of talent and many cultural reasons might cause this top position. Nevertheless, it is important to investigate other venture capital markets and to understand how they work and into which direction they will possibly develop. Results could give hints at how to foster the resource “technopreneurship” (Venkataraman 2004) within a national economy and how to provide it with capital.

A former study investigated venture capitalists’ strategies within the German-speaking region of Europe (Austria, Germany, and Switzerland) (Jungwirth 2004). Accidentally, it found similar differences in investment behavior between Austrian/Swiss and German venture capitalists that were stated between US and European venture capitalists (Bottazzi et al 2004). Austrian and Swiss venture capitalists focus on “later” stage / “lower” tech projects and own less specific knowledge. The result is interesting because Germany, Switzerland, and Austria are one cultural area<sup>1</sup> but differ in terms of geographical size and by the stage of development of the venture capital market. Germany is quite a bit larger than Austria and Switzerland and its venture capital market is rather well established (Becker/Hellmann 2002). Both, market size and market development, could cause these differences in investment behavior and thus

---

<sup>1</sup> “Cultural” comprises here: same language, same university system, similar industry structure, same skill level, same risk propensity etc.

good rationales exist why both factors could have an effect: demand in small markets could be too small to amortize investments in specific knowledge; and a lack of specific knowledge increases the agency costs of high tech investments and with it the risk to fail in early stage / high tech projects. If venture capitalists do not own specific knowledge and do not attend to early stage/high tech projects, they do not have to focus on one or a few industries because no specific knowledge is needed (Jungwirth 2004). A delayed market development on the other side could be reflected in delayed learning and hinder appropriate investments in human capital.

This paper is organized as follows: the next section presents the related literature. Section three discusses the potential effects of market size and market development on the venture capitalists' willingness to thoroughly invest in human capital. Section four presents a unique and hand collected dataset. Venture Capitalists from Switzerland and Austria answered a standardized questionnaire referring to structure, strategic choices, and endowment with human capital, and subjective estimation of the market situation. The Swiss and Austrian markets are similar as to their geographical smallness and their relative late entrance into the venture capital business. Interestingly, they react quite differently to their market conditions. While Austrian venture capitalists seem to be sort of frustrated by the low opportunities of the small market Swiss venture capitalists act quite offensively: they invest much more in their human capital, try to specialize and go for internationalization. However, nationality seems not to be the deciding factor. The more a venture capitalist has invested in human capital the more similar are investment activities of Austrian and Swiss venture capitalists: They invest more in early stage/high tech projects, cooperate more intensively, and estimate the market situation as promising. That is the central result of this study.

## **2. Related literature**

The paper investigates national differences concerning the willingness of venture capitalists to invest in their human capital and focuses on market size and market development as possible influence factors. To my knowledge, this point has not been made in the literature yet. However, Bottazzi et al. (2004) and Jungwirth and Moog (2004) show evidence that investments in specific human capital are the key driver for investment behavior being prerequisite for early stage / high tech investments. While Bottazzi et al. (2004) use the

highest degree of venture capitalists' education (master, PhD) as measure for human capital Jungwirth and Moog (2004) categorize different types of knowledge, namely management knowledge and technical or scientific knowledge. Both studies were able to show that the propensity to do high tech investments correlates strongly with the amount of knowledge a venture capitalist owns.

Regional differences concerning the venture capitalists' predominant portfolio strategies are well known and well investigated within the literature: Bottazzi and Da Rin (2002) as well as Bottazzi et al. (2004) describe the peculiarities of the European venture capital market. They consider big differences between the European and the US venture capital markets concerning the early stage and high tech orientation even if the European venture capital market seems to grow fast. The reluctance of European investors to provide high risk money could be responsible for the fact that the sums invested are growing at a lower rate than in the US. Murray und Lott (1995), Murray und Marriott (1998), Lockett et al. (2002) analyze the bias of UK venture capitalists to invest in high tech portfolios. They also find an investors' reluctance to make risky investments. Additionally, they refer to government policies that evoke a more conservative investment strategy. Schertler (2004) concedes a strong influence of fund providing institutions on the investment strategies of venture capitalists. Banks seem to be much more risk averse than pension funds which are more willing to invest in early stage projects. These results could explain regional differences in investment strategies with differences in the predominance of certain fund providing institutions.<sup>2</sup> Studies investigating the Canadian venture capital industry with the peculiarity of labor sponsored venture capital funds (Cummings 2005) confirm the strong relationship between the fund providing institutions and certain investment strategies.

The peculiarities of certain national venture capital markets are investigated for example by De Clercq et al. (2001) (Finnish venture capital market), Dossani and Kenney (2001) (Indian venture capital market), Peneder and Wieser (2002) (Austrian venture capital market) and Gebhard and Schmidt (2002) (German venture capital market). All studies refer to a delay in realizing learning effects that hinders foreign venture capitalists to act as professionally as US venture capitalists. Results allow the conclusion that the stage of development of venture

---

<sup>2</sup> In Austria for example banks provide 43% of the total amount of venture capital, pension funds provide 14% and private individuals 13%. In Switzerland banks, pension funds and funds of funds provide in each case 30% of the total amount of venture capital. In Germany banks provide 40%, government agencies 24%, and insurance companies 22% of the total amount of venture capital (EVCA 2004: 60-63).

capital markets has an important impact on venture capitalists' strategies. However, also market size should be important, even if I did not find a paper that refers to this influencing factor. The possible influence of both factors, markets size and market development, are explained within the following chapter.

### **3. The role of market size and market development for the willingness to invest in human capital**

#### **3.1 Market size**

Adam Smith (1776) states that "the division of labor is limited by the extent of the market." Small markets do not offer enough demand for specialization. That is also true for venture capital markets where specialization will only take place if the demand for e.g. biotech financing will be high enough. The reason is that the costs of specialization are independent of the amount of portfolio enterprises attended to by venture capitalists. Therefore, only a high demand allows amortizing the set-up costs of specialization (Besanko et al. 2000: 117-122). And a high demand is more probable in large markets. It then follows that market size should in fact influence the willingness of venture capitalists to invest in their human capital.

However, why should regional frontiers determine the size of venture capital markets? Capital can be invested elsewhere and regional frontiers should be meaningless. This is not true for venture capital (also called "smart" capital) where regional closeness foster a successful relationship between venture capitalists and portfolio enterprises. In quite an early paper Tyebjee and Bruno (1984: 1057) point out:

„When a venture capitalist invests in a company, he expects to meet regularly with the management of the new venture. To maintain travel time and expense at manageable levels, some venture capitalists limit their investment activity to major metropolitan areas with easy access. [...] Though most venture capital companies do not actively pursue a policy of restricting their investment activity to a specific geographic boundary, their portfolios often exhibit this specialization because of a tendency of entrepreneurs to search for capital close to their venture's home where their banking, legal and accountancy contacts are strongest.”

And in a recent paper Zook (2002: 151) is convinced that regions remain central to economic development of venture capital markets:<sup>3</sup>

---

<sup>3</sup> See also Lerner (1995) and Sorenson/Stuart (2001).

„The ability to provide these types of value-added inputs in a timely manner is greatly assisted by geographic proximity. Rather than being an easily moved and fungible commodity, venture capital investing depends upon non-monetary inputs such as knowledge about possible investments and prefers to be close to companies in order to monitor and assist them. Thus, despite telecommunications technologies and global financial markets that have vastly expanded the geographic range of economic interaction.“

However, geographical small markets naturally have no problems with distances but they have another one: They do not own a big pool of potential start-ups that compete for venture capitalists' money and is prerequisite for successful investment activities, too. That pool allows venture capitalists to select the most promising projects as well as to match with the most appropriate projects. Nations like the US or Germany, Switzerland or Austria can be understood as pools that comprise potential start-ups, projects, and ideas and feed regional venture capital centers like the Boston region or the Silicon Valley in the US and the Munich or Frankfurt/M. region in Germany (Audretsch/Lehmann 2004: 21). While founders are limited to a certain extent to go where the money is, venture capitalists have to go where the founders are. This explains the development of regional venture capital centers that are often found close to big universities (Audretsch et al. 2004). However, even venture capitalists are not unlimited to follow their projects because leaving their region and/or country they lose a great deal of their (idiosyncratic) knowledge.<sup>4</sup> Therefore, the national market size determines the amount of potential projects to which venture capitalists have access to to a considerable extent. Or the other way around: the national market size determines the demand for venture capital to a considerable extent.

However, in order to estimate the relative market size of Austria and Switzerland some data are needed. The following table presents some statistical data that allow comparing the size of the nation, the size of the venture capital market and the size of the pool of potential projects of Austria and Switzerland. Besides our focused markets data were selected from Germany as reference point within the German-speaking region, from the UK as the most established venture capital market in Europe, from Europe at all and from the US as general reference point.

---

<sup>4</sup> Venkataraman (2004) investigates local prerequisites fostering „technopreneurship“. He refers to factors like access to new ideas, role models, informal forums, region-specific opportunities, safety nets, access to large markets, and executive leadership. It is local knowledge that allows access to these resources. However, in case of cooperation (or syndication) these problems can be mitigated: a so-called lead investor monitors the start-up on location.

**Table 1: Relative market size of Austria and Switzerland compared to other markets**

|  | Austria | Switzerland       | Germany | UK   | Europe | USA   |
|--|---------|-------------------|---------|------|--------|-------|
| <b>Geographical size</b>   |         |                   |         |      |        |       |
| Area (1000 km <sup>2</sup> ) <sup>5</sup>                          | 84      | 41                | 357     | 244  | 4,113  | 9,631 |
| Inhabitants (in Mio) <sup>6</sup>                                  | 8.1     | 7.3               | 82.5    | 59.2 | 454    | 291   |

Source: Own composition but see footnotes.

The data show that national markets differ considerably concerning geographical and economical size, venture capital volume, and potential for start-up projects. I abstain from building relative data (e.g. GDP per capita) because the absolute size of a nation's pool of resources and capabilities is important. Estimating the relative market size of the Austrian and Swiss venture capital markets two points become evident: First, both markets in fact are small compared to Germany and UK. Second, a considerable difference between Austria and Switzerland exists: the Swiss venture capital volume is nearly twice as much as the Austrian one. Nevertheless, it is a small market compared to Germany, UK, and the US.

### 3.2 Market development

Cohen und Levinthal (1990) refer to the need of experience and knowledge, called „absorptive capacity“, as a major factor in being able to learn. Therefore, existing knowledge cannot simply be used to improve a decider’s strategy elsewhere. If the buildup of absorptive capacity is lost in a certain period, the enterprise’s development is eventually prolonged for many periods: The environment’s information cannot be “absorbed” and no learning effects result from others’ experiences within the same enterprise. Therefore, a lack of absorptive capacity can lead to a false estimation of what the market calls for. If the market calls for specialization but venture capitalists do not realize it they will under invest in human capital.

De Clercq et al. (2001) investigated the emerging Finnish venture capital market for the period 1994 through 1997. They were able to show that, during that period, venture capitalists successively specialized the industry scope of their portfolio. They also found evidence that less experienced venture capitalists had a time lag in these investment patterns compared to more experienced ones. They explained these results with delayed learning effects in the young but emerging Finnish venture capital market.

A similar situation could affect the Austrian venture capital market that is well known to be “... still slightly behind when compared to other European countries.” (EVCA 2004: 81).

Peneder (1999) assumes that the traditional Austrian industry structure is responsible for that delay. Officials of the Austrian government and Austrian Private Equity and Venture Capital Association (AVCO) estimate that the Austrian venture capital market has made up and actually is nearly as developed as the neighbor venture capital markets (Peneder und Wieser 2002, Müller 2003) but we know from Cohen and Levinthal (1990) that a lack of experience in one period can affect strategic choices for the next periods. Therefore, path dependencies could be responsible for differences in investment behavior today.

Even Switzerland is described by EVCA (2004: 241) as “lagged behind other similar sized countries such as Finland and Israel”. EVCA (2004) suggests that a lack of entrepreneurial spirit could be responsible for the Swiss delay in building up its venture capital market. This is supported by studies focusing on a characteristic Swiss risk aversion (Hofstede 2001). However, things are more complex. Switzerland possesses capital far above international average but because of certain pension funds regulations (a yearly minimum rate of return of

actually 3.25%) it is quite limited to allocate pension funds money in the high tech sector. Therefore, venture capital has to be brought up by private persons, insurance companies, and banks, which runs it short artificially. Changes in legislation are considered but not realized by now (Volery et al. 2003).

### **3.3 Hypotheses**

If differences in portfolio strategies of less developed markets can be traced back to a lack of experience and knowledge, they should be mitigated in the long run. On the other hand, if market size does not lend itself to specialization, small markets will find its equilibrium on a low specialized level. High-tech investments will be rare because of a lack of knowledge. Both concepts could help to explain national and regional differences in market behavior and to forecast the venture capital market development of a specific country or region. However, it will be hard to separate both effects because the small markets are often the less developed ones. Therefore, the present paper tries to estimate in how far market development and in how far market size affects the portfolio strategies of venture capitalists within a certain market.

To some extent the question can be answered already. Data have shown that the Austrian and Swiss venture capital markets are considerably smaller and less developed than the German, UK, and US ones. And results of a former study affirm expectations that Austrian and Swiss venture capitalists invest relatively lowly in human capital. OLS-regressions show that an Austrian venture capitalist holds 26.5% less specific knowledge than her German colleague (significant on a 5%-level). A Swiss venture capitalist holds 8% less but the second result is not significant. Consequently both, Swiss and German venture capitalists, also show a lower high tech orientation than their German colleagues: An Austrian venture capitalist holds 14.5% less high tech projects in her portfolio (significant on a 10%-level) and a Swiss venture capitalist holds 16.0% less high tech projects in her portfolio (significant on a 5%-level). Additionally both, Austria and Swiss, attend to less specialized portfolios holding 3 (Austria) and accordingly 3.4 (Switzerland) more industries in their portfolio than their German colleagues (significant on a 5%-level) (Jungwirth 2004).

However, I have two problems with these results: First, as mentioned above it is hard to assess if market size or market development effects are responsible for that outcome. Second,

in spite of the same market conditions the portfolio strategies within the group of Austrian and Swiss venture capitalists vary considerably. The question is what method allows to differentiate between the two effects and to explain the variations between venture capitalists. Gabszewicz and Grilo (1992) formed the term of „heterogeneous beliefs“ explaining why equally informed individuals decide differently under the same market conditions. They assumed that beliefs about quality are heterogeneously distributed among individuals reacting rationally but differently. Assigned to our problem I assume heterogeneous beliefs as follows: Austrian and Swiss venture capitalists know that their markets are small regarding access to venture capital as well as access to promising projects. However, it is not clear how they estimate this fact: Does small mean “too small” or “rather small”. The same holds for their assessment of market development: Does a delayed development mean “too late” or “promising”? The market assessment of each venture capitalist allows analyzing how beliefs about market size and market development influence investment activities. This consideration leads to the following testable hypotheses:

1. *Venture capitalist believing the market to have a certain potential for development*
  - a. *show a considerably higher share of industry specific human capital,*
  - b. *specialize on a few industries,*
  - c. *attend to more high tech projects within their portfolio, and*
  - d. *invest in earlier stages.*
  
2. *Venture Capitalists believing the market to be too small*
  - a. *show a considerably lower share of industry specific human capital,*
  - b. *diversify over many industries,*
  - c. *attend rather to “medio” and low tech projects within their portfolio, and*
  - d. *invest in later stages.*

## **4. Database and methodology**

### **4.1 The data**

To test these hypotheses I generated a dataset based on addresses provided by the Austrian Private Equity and Venture Capital Organisation (AVCO), and the Swiss Private Equity and

Corporate Finance Association (SECA). Between November 2004 and January 2005 106 questionnaires were sent out via e-mail<sup>13</sup> and 58 well answered questionnaires were returned (return rate of 54.7%). Comparing the data with EVCA data (EVCA 2004) and AVCO data (<http://www.avco.at/>) and SECA data (<http://www.seca.ch/>) concerning the portfolio volume and the number of portfolio investments, the industry or investment stage orientation, and the geographical activities I assess returns as representative of the population of venture capitalists in Austria and Switzerland.

The standardized questionnaire collected extensive data on the venture capitalists' firm structure and investment focus as well as the type of enterprises they attend, their endowment with knowledge and experience, and their assessment of their home venture capital markets.

(1) **Firm structure and investment focus:** I asked for data that reflects the size of the company (measured in numbers of employees, number of portfolio companies, and the volume of the portfolio), company's development since foundation, the spatial focus of the company (regional, nationwide, or international), and the governance structure (being an independent business or not). Concerning the investment focus of the venture capitalist, I asked to what degree the venture capitalist was specialized in an industry (measured by the number of industries a venture capitalist is investing in, ranging from one industry - being more of a specialist - up to seven and more industries and thus being more a generalist or all-rounder, as the venture capitalists called themselves).<sup>14</sup> I need these data to control for differences across venture capitalists.

(2) **Knowledge and experience** to which the venture capital firm has access: the survey comprised information about education (the kinds of studies they had pursued and the kinds of university degrees they had obtained) and experiences of the employees and founders of the venture capital companies (industries in which they had obtained working experience).

(3) **Assessment of the venture capital market:** Questions referred directly to problems that deal with market size and market development. Mr. Thomas Jud, chairman of the AVCO, discussed all the statements with us and helped us to find items well known to all venture capitalists. Transferring the questionnaire to the Swiss venture capital markets I asked SECA

---

<sup>13</sup> All companies did have email access. However, I offered them to send the questionnaire by email, by mail or by fax to increase the response rate. Only 10 percent of all responses did not return by email. Offering the other two possibilities to send back the questionnaire I could ensure that there was no response bias concerning the online survey technique (for more information on this kind of survey technique see Isfan and Moog 2003).

<sup>14</sup> I aggregated industries in seven fields, usually named by venture capitalist as typical investment fields, namely bio-technology, computer software, medicine, electrical engineering, computer hardware, communication technology, internet/e-commerce.

for support. They approved the importance of the items also for Switzerland. I will give an account of these items under “operationalization” because they are really important for the results of the analysis.

## 4.2 Methodology

Hypotheses claim a relationship between market assessment and investment behavior. Referring to Gabszewicz’s and Grilo’s (1992) heterogeneous beliefs – assessments of qualities, which are accidentally distributed among individuals within a certain population – I ask in how far the assessment of market size and market development influences investment behavior. A multivariate OLS regression seems appropriate to analyze this relationship in so far as a direct and linear relationship between market situation and investment behavior could be motivated within the theoretical part of the paper. Therefore, I test the influence of market assessment and some control variables at any one time on the dependent variables “investments in human capital” (HCSPEC), “investments in high tech projects” (HIGHTECH) and “in early stage projects” (FINSTAGE) as well as on “degree of specialization” (DEGRESPEC).

**Table 2: Estimated OLS Equations**

|           |   |  |
|-----------|---|--|
| HCSPEC    | = | $\alpha + \beta_1 \text{ EMERGINGMARKET} + \beta_2 \text{ GOODPOTENTIAL} + \beta_3 \text{ ENOUGH SUPPORT} + \beta_4 \text{ TOOSMALL} + \beta_5 \text{ WILLDEVELOP} + \beta_6 \text{ LITTLEPOTENTIAL} + \beta_7 \text{ VOLPERPU} + \beta_8 \text{ DUMMYCORP} + \beta_9 \text{ DUMMYDEPEND} + \beta_{10} \text{ AGEOFVCFIRM} + \beta_{11} \text{ EXPSPEC} + \varepsilon$ |
| HIGHTECH  | = | $\alpha + \beta_1 \text{ EMERGINGMARKET} + \beta_2 \text{ GOODPOTENTIAL} + \beta_3 \text{ ENOUGH SUPPORT} + \beta_4 \text{ TOOSMALL} + \beta_5 \text{ WILLDEVELOP} + \beta_6 \text{ LITTLEPOTENTIAL} + \beta_7 \text{ VOLPERPU} + \beta_8 \text{ DUMMYCORP} + \beta_9 \text{ DUMMYDEPEND} + \beta_{10} \text{ AGEOFVCFIRM} + \beta_{11} \text{ EXPSPEC} + \varepsilon$ |
| FINSTAGE  | = | $\alpha + \beta_1 \text{ EMERGINGMARKET} + \beta_2 \text{ GOODPOTENTIAL} + \beta_3 \text{ ENOUGH SUPPORT} + \beta_4 \text{ TOOSMALL} + \beta_5 \text{ WILLDEVELOP} + \beta_6 \text{ LITTLEPOTENTIAL} + \beta_7 \text{ VOLPERPU} + \beta_8 \text{ DUMMYCORP} + \beta_9 \text{ DUMMYDEPEND} + \beta_{10} \text{ AGEOFVCFIRM} + \beta_{11} \text{ EXPSPEC} + \varepsilon$ |
| DEGRESPEC | = | $\alpha + \beta_1 \text{ EMERGINGMARKET} + \beta_2 \text{ GOODPOTENTIAL} + \beta_3 \text{ ENOUGH SUPPORT} + \beta_4 \text{ TOOSMALL} + \beta_5 \text{ WILLDEVELOP} + \beta_6 \text{ LITTLEPOTENTIAL} + \beta_7 \text{ VOLPERPU} + \beta_8 \text{ DUMMYCORP} + \beta_9 \text{ DUMMYDEPEND} + \beta_{10} \text{ AGEOFVCFIRM} + \beta_{11} \text{ EXPSPEC} + \varepsilon$ |

Own Analysis 2005

I checked the model for linearity, multi-collinearity<sup>15</sup> and for heteroscedasticity (Wooldridge 2003) and found it valid leading to meaningful results.

<sup>15</sup> No correlation coefficient was higher than 0.502.

### 4.3 Operationalization

The next step is to operationalize our dependent, independent, and control variables.

#### *Dependent variables:*

First, I refer to the willingness of venture capitalists to invest in their human capital. The variable is called HCSPEC. Venture capitalists' knowledge is categorized on the basis of gathered information about the higher education of the firm's employees and founders. If they only have a degree and/or experience in business administration or law, they are categorized as having 'general knowledge'. If they have degrees or experience in science or technology, they have 'specific knowledge'. In fact, most of the companies have a knowledge mix that is specified by a percentage grading of specific knowledge. For instance: having two 'masters of business administration' and one lawyer and one technical scientist within the team yields a share of specific knowledge of 25% ((one specialist/venture capital managers at all) x 100). The second dependent variable within the multivariate regression model describes the share of high tech enterprises within the venture capitalists portfolio. I asked venture capitalists about their portfolio composition and gained the variable HIGHTECH directly. The degree of specialization (DEGRESPEC) is operationalized as amount of industries within the venture capitalist's portfolio. Venture capitalists selected industries according to a given sample and I counted their ticks. If they said they were an "allrounder" they got a ten. The lower the variable DEGRESPEC the higher is the degree of specialization of a venture capitalists because the variable reflects the number of industries within the venture capitalist's portfolio. The last dependent variable FINSTAGE differentiates early-stage investors and late-stage investors. I asked venture capitalists in which stages they invest. Early stage investments got a negative value and late(r) stage investments a positive value while "stage allrounders" got the value zero. Adding these values I built a scale from -1 (early stage investments) to +2 (late stage investments) that allows to categorize a venture capitalists as early or late stage investor.

#### *Independent variables*

The assessment of market size and market development is assumed to explain investment behavior of venture capitalists. The basis for this assessment is the following set of items that was part of the questionnaire. Two items were dropped because they did not reveal evidence to influence investment behavior of venture capitalists. The names of the other variables are put in the brackets behind the items.

1. With its risk-taking and committed founders, the Austrian/Swiss market gives rise to a quick establishment of the venture capital market. (EMERGINGMARKET)
2. The Austrian/Swiss market contains many innovative projects and, therefore, possesses a considerable potential for venture capital. (GOODPOTENTIAL)
3. With its tax and legal conditions, the Austrian/Swiss market supports the activities of venture capital companies. (ENOUGHSUPPORT)
4. The Austrian/Swiss market is too small to specialize in one or some branches. (TOOSMALL)
5. The Austrian/Swiss market is still in its infancy concerning venture capital. (WILLDEVELOP)
6. The Austrian/Swiss market has little potential for the high-tech projects, since the innovative activities take place within the existing industrial structures.” (LITTLEPOTENTIAL)

The items went into the regression analysis as the statement was made for the following reason: A factor analysis offered three clear distinguishable factors that comprised a very positive assessment of the market, a positive but reluctant assessment of the market, and a quite negative assessment of the market. However, using these factors as independent variables results showed clearly less evidence compared to the original items. The reason could be that every form of dimension reducing method loses information. In that case the factors mixed items concerning market size and market development but these factors revealed to be important in later analysis. Therefore, the original items are used. Being measured on a Likert scale, variables can be handled as metric variables because all of them showed a normal curve of distribution. Again, the independent variables are: EMERGINGMARKET, GOODPOTENTIAL, ENOUGHSUPPORT, TOOSMALL, WILLDEVELOP, AND LITTLEPOTENTIAL.

*Control variables:*

However, I know that apart from market assessment many other factors probably exist influencing the investment behavior of venture capitalists. A very important one is the amount of venture capital that is available to each venture capitalist. To differentiate between venture capitalists investing small amounts in many firms and venture capitalists putting “all eggs within one basket” I divided the invested volume of capital by the amount of portfolio enterprises attended. This variable is called VOLPERPU. We learned in section two that institutions matter. Therefore, I built two dummy variables stating if a venture capitalist is a corporate or another dependent venture capitalist. Reference category for both, corporate and other dependent (banks, governmental agencies) venture capitalist, is the class of independent venture capitalists. In the questionnaire I also asked if the venture capital firm depends on a mutual saving bank but no venture capitalist ticked this possibility. Therefore, I have only three institutional categories and the two I use are called DUMMYCORP and DUMMYDEPEND. I also know that the Swiss and the Austrian venture capital market differ regarding the amount

of venture capital available. That seems to be an important influencing factor so that controlling for country is worth while (DUMMYAUSTRIA). Another relevant factor independent from “market experience” should be the individual experience of a venture capitalist. The age of the venture capital firm can be used as proxy for experience (AGEOFVCFIRM). Venture capitalists indicated when they were founded (e.g. 1995). This year was subtracted from the actual year 2005 and delivered e.g. an age of 10 years. Another variable referring to specific experience (EXPSPEC) was build analogous to the share of specific human capital. A value of e.g. 75% means that  $\frac{3}{4}$  of venture capitalists collected their experience in a specific industry while  $\frac{1}{4}$  collected their experience in a bank, public administration or consulting firm.

The following table sums up all dependent, independent and control variables.

**Table 3: Definition of variables and descriptive statistics (n = 58)**

| Variables                    | Meaning   | Measure   | Medium | Standard deviation |
|------------------------------|---|---|--------|--------------------|
| <b>Dependent variables</b>   |   |   |        |                    |
| HCSPEC                       | Share of specific human capital within the VC firm        | Percent, metric   | 28,06  | 29,56              |
| HIGHTECH                     | Share of high tech projects within the VC's portfolio     | Percent, metric   | 52,38  | 36,90              |
| FINSTAGE                     | Predominant stage of financing of a VC firm               | Scale from -1 (early stage) to +2 (late stage), quasi metric                  | 0,63   | 1,00               |
| DEGRESPEC                    | Numbers if industries within VC's portfolio               | 1 to 10, Metric   | 5,91   | 3,55               |
| <b>Independent variables</b> |   |   |        |                    |
| EMERGINGMARKET               | Positive assessment of market development                 | Likert scale from 1 (I completely disagree) to 5 (I completely agree), metric | 2,32   | 0,81               |
| GOODPOTENTIAL                | Positive assessment of market development                 | Likert scale from 1 (I completely disagree) to 5 (I completely agree), metric | 3,32   | 0,96               |
| ENOUGHSUPPORT                | Positive assessment of governmental support               | Likert scale from 1 (I completely disagree) to 5 (I completely agree), metric | 2,89   | 1,21               |
| TOOSMALL                     | Negative assessment of market size                        | Likert scale from 1 (I completely disagree) to 5 (I completely agree), metric | 3,73   | 1,23               |
| WILLDEVELOP                  | Positive assessment of market development                 | Likert scale from 1 (I completely disagree) to 5 (I completely agree), metric | 3,61   | 1,00               |
| LITTLEPOTENTIAL              | Negative assessment of market size                        | Likert scale from 1 (I completely disagree) to 5 (I completely agree), metric | 2,40   | 0,83               |
| <b>Control variables</b>     |   |   |        |                    |
| VOLPERPU                     | Investment volume divided by portfolio enterprises        | Million Euro, metric  | 6,03   | 7,15               |
| DUMMYCORP                    | Corporate VC  | 1 = Corporate VC<br>0 = Independent VC  | 0,06   | 0,23               |

#### 4.4 Descriptive results

I deal with two different countries. Therefore, I want to know if significant differences exist in variable values between Austria and Switzerland. Results show considerable differences concerning investments in knowledge (HCSPEC) and portfolio management (HIGHTECH, DEGRESPEC). Swiss venture capitalists on average act more professionally owning more specific human capital, attending to more high tech projects and being more focused on a few industries. Interestingly, I could not find these differences in the 2003-study. I interpret this result as evidence for a different development of Austrian and Swiss venture capital markets since 2003. Comparing Austrian and Swiss venture capitalists' market assessment I also find significant differences concerning the items ENOUGH SUPPORT and TOO SMALL. Obviously, Austrian venture capitalists in average feel better supported by government. Swiss venture capitalists on the other hand assess market size as less problematic. These results seem to approve that venture capitalists indeed understood the meaning of the items. Austrian government actively fosters the venture capital market by supporting it with transaction cost reducing services while Swiss government acts quite reluctantly (Lüthy 2004). And the Austrian venture capital market is indeed smaller by size namely half in terms of venture capital available. Two other significant differences lie in the venture capitalists' status and in the experience they have gathered. While Austrian venture capitalists in many cases are dependent, Swiss venture capitalists are rather independent. Even this can be assumed to reflect the stronger participation of Austrian government in the venture capital market. The fact that Swiss venture capitalists own more managers with experience gathered in the industry also argues for a more professional approach in venture capital business.

Own Analysis 2005. \*\*\* Significant on 0%-level; \*\* significant on a 1%level; \* significant on a 5%-level

However, our central question is not in how far Austria differs from Switzerland but in how far beliefs about market size and market development influence investments in human capital and portfolio management. I expected that venture capitalist believing the market to have a certain potential for development show a considerably higher share of industry specific human capital, specialize on a few industries, attend to more high tech projects within their portfolio, and invest in earlier stages. Venture Capitalists on the other side believing the market to be too small should show a considerable lower share of industry specific human capital, diversify over many industries, attend rather to “medio” and low tech projects within their portfolio, and invest in later stages. Correlation analysis revealed that venture capitalists

assessing the market as too small invest less in human capital, in later stages and hold more industries in their portfolio. Venture capitalists on the other side expecting the market as a developing one invest in earlier financing stages and hold fewer industries in their portfolio (all results significant on a 5%-level).

#### **4.5 Results from regression analysis**

Concerning investments in human capital (Table 5) I find that the assessment of the market as too small seemingly leads to lower investments in specific human capital. The size of the effect is quite considerable: one point on the Likert-scale leads to a change in investments of more than 7%. However, venture capitalists who do not believe that the markets have enough high tech potential invest considerably more in their specific human capital. That is a quite contradicting result that is hard to explain. Interestingly and unexpectedly, I find that dependent venture capitalists invest much more in specific human capital than independent venture capitalists. I know from T-statistics that dependent venture capitalists are rather found in Austrian than in Swiss firms. I interpret this result that in the case of Austria institutions own more absorptive capacity and other resources and, therefore, are able to learn faster than independent “lone fighters”. The Dummy Austria delivers the expected result that Austrian venture capitalists invest considerably less in specific human capital than Swiss ones. Regression results support the expectation that beliefs about market size influence the propensity to invest in specific human capital.

Concerning investments in high tech projects assessment of the market does not show any influence. However, I find some unexpected results here: The higher the venture capitalist's investment volume per project, the lower is her share of high tech projects within her portfolio. And the older the venture capitalist is, the less she invests in high tech projects. Results reflect a considerable risk aversion and the opposite would make sense. Both, a higher investment per high tech project as well as more experience of the venture capitalist, would make the investment's success more probable. It is also contradictory to the finding of De Clercq et al. (2001) that the more experienced venture capitalists focus more on high tech projects. However, being an Austrian venture capitalist or a Swiss one makes the difference: Austrian venture capitalists can be expected to invest 41% less in high tech projects than their Swiss colleagues. That is a huge difference and reflects a different state of the market.

Regression 3 analyzes the relationship between the beliefs about the market and the financing stage a venture capitalist chooses. The later she places her investment, the less risky the investment is. First, regression 3 reveals why factors from the factor analysis did not sharpen up results from the regression analysis. While venture capitalists assessing the market as developable (GOODPOTENTIAL and WILLDEVELOP) invest in earlier stages – as expected – venture capitalists assessing the market as too small (TOOSMALL) invest in later stages – also as expected. However, venture capitalists assessing the market as emerging in general (EMERGINGMARKET) invest in later stages. The “emerging market” item is more general and, therefore, it could reflect a quite unspecific belief about the market situation. That could explain that this belief is not linked to the expected reaction. Another result is that corporate venture capitalists invest considerably later than independent venture capitalists. That reflects the business model of corporate venture capitalists supporting companies that often have been started in-house and are hived off later (Maula et al. 2005). At last I find a flimsy hint that more experienced venture capitalists invest earlier. All in all this regression supports the expectation that beliefs about market size and market development influence investment behavior.

**Table 7: Regression 3 - Investments in an Early or Late Financing Stage**

The last regression analyzes the influence of beliefs on the degree of specialization. In the theoretical part of the paper I argued that a small market will not amortize investments that are necessary for specialization and, therefore, specialization will stay on a low level. If individuals on the other hand expect a developing market, specialization should be superior because specialization now prepares competitive (first mover) advantages in a later period. Results show that the assessment of the market as a developing one leads to a significantly higher degree of specialization. Venture capitalists who believe that the venture capital market is promising and will develop, hold fewer industries in their portfolio than others. However, the assessment of market size does not show a significant reaction even if result shows into the right direction. And venture capitalists who believe that their venture capital markets have little potential for high tech projects, also hold fewer industries in their portfolios. That fits the result of the first regression where the belief “little potential” led to higher investments in human capital. Austrian venture capitalists – as expected – hold nearly three more industries in their portfolio than Swiss venture capitalists. All in all expectation can be supported that beliefs about market size and market development influence the propensity to specialize.

## 5. Discussion and Conclusion

The question of this paper has been in how far beliefs about market size and market development influence the investment behavior of venture capitalists. Investment behavior refers to investments in specific human capital, investments in high tech projects, investments in early stage projects, and it also refers to a focus strategy limiting the portfolio to one or a few industries. All parts of this investment behavior are closely linked to each other: Venture capitalists need specific human capital to be able to deal with the principal agent problems of early stage/high tech projects (Jungwirth/Moog 2004, Dimov/Shepherd 2005). However, because they cannot build up more than a few stocks of specific human capital they have to focus on a few industries. The paper analyzed if and in how far a small market size and a delayed market development would bar venture capitalists from specialization. The rationale was that the demand in small markets is too small to amortize the investments in the specific stock of human capital. In delayed developed markets on the other hand, a lack of absorptive capacity deters venture capitalists from understanding adequately what the market calls for. From a former study I knew that the Austrian and Swiss venture capital markets are small and lately developed. I also knew that the Austrian and Swiss venture capitalists invested less in human capital, in early stage/high tech projects and are broader diversified. However, I did

not know how much of this investment behavior refers to market size and how much refers to the delayed market development. Another point was that variations between venture capitalists in the control sample were considerable. Therefore, it could be assumed that not the objective market situation should be relevant for investment behavior but the subjective assessment of the market situation should be the crucial factor. The questionnaire asked some important items concerning market assessment of the Austrian and Swiss venture capital market that were taken as explanatory variables.

Results are illuminating but ambivalent for two reasons:

First, beliefs about the market show a considerable and significant influence on investment behavior. Mostly they support expectations but sometimes they seem to be contradictory. E.g. the two items “the Austrian/Swiss market is too small to specialize in one or more industries” and “the Austrian/Swiss market has little potential for high-tech projects, since the innovative activities take place within the existing industrial structures” consistently lead to different reactions in investment behavior: While the “market is too small” belief leads to less investment in human capital and to a broader diversification the “little potential for high-tech projects” belief leads to the opposite. Obviously, a relationship that is quite logic and clear for me is not as matter of course for venture capitalists.

Second, the strongest influence on investment behavior is being an Austrian venture capitalists or a Swiss one. That is – in a sense – a strong support for our hypotheses: Starting from nearly the same investment behavior in the beginning of 2003 differences in market size (measured as venture capital available) led to considerable differences in investment behavior in the beginning of 2005. To assure that national effects are not caused by certain non-discussed influence factors (e.g. tax regulation that punish high tech investments) I compared venture capitalists with more general knowledge and venture capitalists with more specific knowledge and found that national differences become less important: An Austrian venture capitalist owning a high share of specific human capital behaves similar as her Swiss colleague owning a high share of specific human capital.

However, what can I say about the influence of market development and market size? At first glance it seems that market size accelerates market development. However, another factor could distort evidence. Switzerland is a financial center and financial knowledge is deep-

seated as a national resource. Therefore, it is not clear if venture capital is provided because of the knowledge or if the venture capital provided fostered the building up of knowledge. Nevertheless, I could show that market size and market development are crucial for investment behavior of venture capitalists. And that is what I wanted to show.

The limits of the study are obvious: Dealing with 58 cases is a good number relative to the Swiss and Austrian venture capitalists available but quite a small number for meaningful regression analysis. Nevertheless, results are quite robust as the specifications of different models show. The next step lies in a refinement of the regression analysis trying to find some more elaborated results using a linear probability model.

## **ABSTRACT**

This qualitative exploratory study is based on interviews with 29 entrepreneurs on spirituality and work. Information from the interviews was organized using *Atlas.ti* software, resulting in an interesting conceptual framework. The findings are organized around four research questions: (1) What motivated the entrepreneur to get into business? (2) How do entrepreneurs find meaning and purpose in their lives? Did the choice to start their own business influence perceived meaning and purpose? (3) How do entrepreneurs view spirituality? (4) How do entrepreneurs view success? Key purposes of the study were to add the entrepreneurial perspective to current literature in the field of spirituality in the workplace; and to explore entrepreneurs' motivations with regard to how their businesses may bring meaning and purpose to their lives. Respondent entrepreneurs were frequently influenced by family role models. Difficulties with previous careers were also instrumental in the decision to start a business. Most entrepreneurs expressed some dissatisfaction with previous positions or bosses. They felt the job they left could be performed equally well or better on their own. The interviewed entrepreneurs realized meaning and purpose through accomplishment, filling a need, as well as through the aspects of love, appreciation, and respect. The entrepreneurs were proud of their accomplishments. Money is a large factor, but is not the only factor in this group's definition of success. Success was better realized by serving people, enjoying repeat customers, building relationships, helping staff grow, and 'loving what you do.'

## **INTRODUCTION**

In conventional thinking, work and spirituality do not seem to go together. Work is about making money and creating value for oneself and the organization. Spirituality is about transcendence and understanding *Self*. The two concepts seem to be at opposite ends of a spectrum. However, interest in spirituality in the workplace is growing. Spirituality at work has become a subject of popular articles in periodicals, books, and scholarly research journals, mostly in the context of larger organizations. The examination of spirituality in the workplace is wide-ranging, both in attempts to define this construct (Khanna and Srinivas, 2000; Levine, 1994, Boozer, 1998; Sperry, 1997, Ashmos and Duchon, 2000; Mitroff and Denton, 1999) and in comparisons with spirituality in the context of religion (McKee, 2003; Mitroff and Denton, 1999; Gibbons, 2000.)

Entrepreneurial research has studied entrepreneurs in the context of various psychological attributes of the entrepreneur (Stewart, 1996; McClelland, 1961; Drucker, 1985.) It has also examined social and cultural factors that promote entrepreneurship (Dollinger, 2003.)

Entrepreneurs are an important group of business professionals to examine in pursuit of the relationship between work and spirituality. In examining the relationship between entrepreneurship and spirituality, it would seem that if the entrepreneur views business as a

vocation or calling she may find more satisfaction, meaning, and fulfillment from it (Leider, 1997.) Exploring these different perspectives can provide insight as to different motivational factors that drive individuals to start businesses. This information will be useful for both educators and students in learning the various reasons why someone would become an entrepreneur. Starting one's own business may be less about making money, security, or flexibility and more about finding meaning and purpose in life.

To better understand what drives entrepreneurs, the researchers interviewed 29 entrepreneurs to seek personal opinions as to: motivations for starting the business, enjoyment of work, definition of success and whether being an entrepreneur provides a greater opportunity to achieve a sense of meaning and purpose. This research explores whether and how the entrepreneurial experience of enterprise creation moves people toward more satisfaction and purpose to achieving a calling in life. Through in-depth conversations with these entrepreneurs, the researchers have explored their motivations for starting a business, as well as how they perceive spirituality, meaning, and purpose.

## **LITERATURE REVIEW**

### **The Modern Workplace**

Accelerating change in the workplace, whether derived from technology, or downsizing/rightsizing tends to create a sense of chaos and instability, blocking the individual quest for meaning. In order to compensate for the sense of deprivation as well as absence of perceived individual meaning and worth within the large organizational setting, many are embracing a spiritual (not necessarily religious) focus. Often, religion assumes a sectarian orientation, one that is more doctrinaire; it can create division rather than unity. The individual focus on spirituality tends to be more tolerant of heterogeneity.

The need to develop connection and a sense of community has become increasingly important, yet the traditional sources such as family and religion are often found lacking in this regard (Conger, 1994; Jung, 1933; Spencer, 1996.) As the workplace has become an increasingly dominant element of life, individuals are seeking some sense of spirituality within it. The experience of dislocation in the workplace and the loss of spirit experienced by many in larger organizations have been the impetus to force individuals out of their comfort zone – to consider what is truly meaningful. The heightened sense of insecurity, loss of connection to the *Self* and personal values, have prompted individuals to reconsider how to pursue their careers. It is likely that this is at least one impetus for the increase in entrepreneurship education evident in universities during the past decade (Solomon, 1998) as well as the increase in small business start-ups (Pulley, 1997.)

Work must provide people with something more than conventional rewards if they are to fully employ personal capabilities (Auger & Arenberg, 1992; Secretan, 1997.) Individuals who experience work as a calling are able to pursue work as an opportunity to enhance their sense of wholeness, energized by spiritual connection with others (Depree, 1989; Marcic, 1997; Morris, 1997; Stein & Hollowitz, 1992.)

There clearly seems to be a drive to find work that is more meaningful and purposeful. Many individuals are feeling a loss of job security and disconnect from their values. As such, there is a continued growth in entrepreneurial businesses. Nevertheless, do entrepreneurs really have a different experience of work than individuals that are employed by others? What are the

measures that entrepreneurs use when defining their success? These questions are the bases for the present study.

### **Entrepreneurs: What is important to them?**

The number of entrepreneurs has continued to rise over the years. The main reason given for the attraction to self-employment are freedom from rules and regulations normally associated with a more formal organization (Chay 1993; Ketz de Vries 1980,) freedom to make decisions, accountability to oneself, potential for higher rewards, opportunity to do challenging work, and a feeling of achievement and pride (Akande 1994; Begley and Boyd 1987; Rodgers and Rodgers 1989; Timmons 1978.)

The above research suggests that entrepreneurs are more creative, happier with their jobs and enjoy opportunity to find alignment with personal values. All of these criteria are in line with human intrinsic motivation to fully experience spirituality in work. (King-Kauanui, 2002.)

### **Defining Spirituality in Organizations**

Researchers are trying to define spirituality in the workplace. This has proven quite the challenge, as the concept does not lend itself to a single idea. Mitroff talks about the definition 'obsession' of researchers in the field of spirituality at work in a recent interview with Kathy Lund Dean (Dean, 2004.) He says, ". . . the fact that there is no single definition to spirituality should not deter us from study of the field." It is reasonable to research the concept without an exact definition of 'spirituality at work.' Allowing entrepreneurs to give their own perceptions, feelings, and responses to spirituality allows for a personal and unaltered perspective. It therefore, seems reasonable to conduct this research by directly seeking this information from respondents.

### **Entrepreneurship**

Entrepreneurship has been analyzed from numerous perspectives such as the entrepreneurs' psychological characteristics, sociological influences, personal motivation, and even definition of success. Some aspects of entrepreneurship depend less on the psychological makeup of the individual than on the situational forces, familial influences, role model, and cultural forces that the entrepreneur faces. These factors are then activated or moderated by the desirability and feasibility of going into business (Dollinger, 2003.)

Researchers have suggested that the reasons people start their own businesses include not only innovation, independence, and vision (Amit, et. al., 2000,) but also self-fulfillment, achievement, and a desire to help others (Pokela, 1989.) Several studies of entrepreneurs that examined motivating factors have found that money was not the most important factor (Amit et al., 2000; Alstete, 2002; King-Kauanui, 2003; Katz, 1992; Kolvereid, 1996; Brenner, Pringle and Greenhaus 1991.)

If the motivation for an entrepreneur is something other than financial, looking at the personal definition of success in business may provide a glimpse into what the entrepreneur finds most meaningful. King-Kauanui, (2003) conducted a study over a 3 year period in which university students surveyed 152 entrepreneurs. The entrepreneurs were asked many open-ended questions from a structured survey, but with emphasis on one question, "how do you define success?" (King-Kauanui, 2003.) The factors most often indicated are: being happy, achieving a dream, making money, helping others, and personal freedom. These results show that entrepreneurs are predominantly interested in personal satisfaction, freedom, and enjoying what they do.

Therefore, it is logical to frame this research on spirituality at work in terms of motivation to start a business, definition of meaning and purpose, and perceptions of the meaning of success.

## **METHODOLOGY**

### **Research Design**

It is consistently clear that the subject matter of spirituality does not lend itself to short answers or neat Likert scale type questions (Fornaciari & Dean, 2001.) No simple prescriptive answer is available to encompass all aspects of an entrepreneur's behavior or view of spirituality.

Therefore, an exploratory qualitative research design was chosen. A semi structured interview process, based on a broad set of questions, was used to gain a better understanding of the entrepreneurs' real experiences, as well as to gather pertinent demographic information. Specifically, the interviews were designed to explore the following research questions to understand how entrepreneurs might be better able to integrate the search for spirituality into their work:

- (1) What motivated the entrepreneur to get into business?
- (2) How do entrepreneurs find meaning and purpose in their lives? Did the choice to start their own business influence perceived meaning and purpose?
- (3) How do entrepreneurs view spirituality?
- (4) How do entrepreneurs view success?

### **Sample Selection**

The sample consisted of 29 practicing entrepreneurs from California and neighboring states. This convenience sample was drawn from lists obtained through alumni groups of Cal Poly Pomona and Cal State Fullerton, as well as entrepreneurship networking circles and professional contacts. Although most were based in California, some respondents conducted business in neighboring states. Therefore, no defined location was placed on the study. Respondents differed by gender, ethnicity, nationality, age, and years in business and came from a variety of professional and educational backgrounds.

### **Data Collection**

The researchers used established, ethical practices for interviewing all subjects. This included disclosing the purpose of the study along with the promise of confidentiality. A confidentiality agreement was proposed, however, most participants were comfortable with a verbal explanation of the process. The interviews were conducted either in person or over the telephone. They were taped, with the entrepreneur's permission and later transcribed. The definition of spirituality at work was not presented to the potential respondents. This way they were not limited to agreeing or disagreeing with the definition. Rather, an open-ended question similar to the one used by Mitroff and Denton (1999) was asked to ascertain the respondent's views on spirituality and then followed up with questions about meaning and purpose of business life.

### **Data Analysis**

The resulting manuscript files were saved in rich text format. A software product called *Atlas.ti* was utilized as the repository and data analysis tool for the project. This software aided in the analysis and interpretation process by creating an environment for organizing, coding, clustering and annotating the large volumes of collected text. This software enabled researchers to extract pertinent quotes and phrases through the use of coding and keyword searches.

## RESULTS

### Demographics

Demographic information about participating entrepreneurs was gathered. This section provides a description of the demographics of the sample. Twenty-nine individuals were interviewed for the study, 16 of the respondents (55 %) were male and 13 or 44 % were female.

### Age

The average age of the respondents was 51 years. Table 1 illustrates the different age categories of the participating entrepreneurs.

---

Table 1 about here

---

### Question 1: What motivated each entrepreneur to get into business?

The preliminary ideas drawn from the literature review were that there are certain influencers or motivators that push entrepreneurs toward getting into business. The aspects of family, previous careers, and socioeconomic factors were known influencers in starting a business and are discussed below. The last section explores the other motivators given as reasons to start a business.

**Role of family:** Entrepreneurs were asked about the role of family in their business. 25% mentioned specifically that their mother or father had been in business for themselves. Some respondents discussed family events that led to starting the business. Several were driven to start their own business so they could do something different. Family events played a role in influencing some entrepreneurs. In some instances, tragedies in the family triggered a need to depend upon themselves. For example, one entrepreneur came from a poor family and as a young man began selling flowers for extra money. Another entrepreneur's spouse had cancer and the reality of her impending death gave him courage to start the business. Another entrepreneur's marriage and family fell apart and the entrepreneur chose to focus on the business rather than dwelling on the devastation of his personal life.

**Role of entrepreneurs' previous career:** The entrepreneurs interviewed rarely started in a completely unknown business. Many had worked in businesses that were similar to the ones they currently owned. Disagreement with management, control of their own destiny, and using the new company to give back to the community were some of the reasons for some entrepreneurs to start their own business. As employees, many entrepreneurs expressed that their good ideas were not being heard. They felt that they could manage processes better than their company or they did not get along personally with the old boss. Navigating the many layers of bureaucracy took too much time and energy. Several felt they had hit the ceiling of opportunity in the company. Some spoke of waking up one day to the realization that they would be doing the same job in twenty years if they did not make a change. Therefore, they went out on their own seeking independence and control of their destiny. Most had at least one or more clients that would remain loyal when they started their business. They felt that the risk was manageable because of experience in the field and a potential client base.

**Role of entrepreneurs' socioeconomic factors:** The role of socioeconomic factors in this study related to the entrepreneurs' history. Some entrepreneurs stated they were selling things at a young age or had experiences in their youth that formed desires to be successful later in life. Others felt that the economic rewards of their previous positions were not in line with the effort

they expended. They wanted more control over the rewards they received from their efforts. Some entrepreneurs were motivated by the prospect of success after an upbringing in poverty. For them, the success of their company had a direct connection to personal feelings of self-worth. They described the feeling that there was no option but success. One entrepreneur said he had to succeed in order not to disappoint because he had put himself “out there for family and friends to see.” Other entrepreneurs recounted the experience of working very hard for a previous employer without fair reward. One entrepreneur said, “. . . if I had stellar performance and accomplished things, the benefit to me was so infinitesimally incremental that it was personally insulting.” The desire to create and obtain equitable rewards for hard work was very strong.

**Other factors:** The rank order of themes from responses about motivation to start a business is illustrated in Table 2. The most often cited themes were: ‘to serve people, better work environment, and money.’ The themes of ‘passion, challenge, creativity, independence, autonomy, necessity, and fear’ were mentioned less often. These responses were part of a discussion in response to the question, “. . . what motivated you to start your business?” The entrepreneurs chose topics and areas that were important to them in the framework of motivation to start the business.

---

Table 2 about here

---

These entrepreneurs favored creating more economic opportunity, a better working environment including the ability to choose staff and clients, and the flexibility to meet the demands of work and family. The flexibility to set schedules, to meet family obligations and special events and the flexibility to decide how to schedule their work were all important.

In Table 3, these ten major themes with number of responses are listed and positioned from ‘more altruistic’ to ‘less altruistic.’ Several of the entrepreneurs mentioned more than one theme, for example, one entrepreneur who indicated ‘service to other people’ as a factor to start a business also mentioned ‘money.’ Approximately 40% of the responses are toward the ‘more altruistic’ end of the scale with 60% at the ‘less altruistic.’

---

Table 3 about here

---

**Question 2: How do entrepreneurs find meaning and purpose for their life? Did the choice to start their own business influence their perceived meaning and purpose?**

Table 4 illustrates the themes or ways respondent entrepreneurs indicated that they found meaning and purpose. The most often cited theme was ‘accomplishment’ was expressed by such comments as, “. . . building something that had not previously been built,” “. . . getting pleasure from a job well done,” “. . . sense of accomplishment from doing the job well.” The second most often cited theme was the ability to ‘fill a client’s need.’ A great sense of pride comes when customers are well served, happy, and return for another transaction. Entrepreneurs generally had a clear sense of how customers should be treated. Perhaps the other themes can be summed

up in the frequent comment by respondents “do unto others as you would have them do unto you” as a principle guide for all business dealings.

---

Table 4 about here

---

### **Question 3: How do entrepreneurs view spirituality?**

In order to get a better understanding of how entrepreneurs viewed spirituality, questions were structured to create discussion about the importance and relevance of spirituality in their business. Some of the entrepreneurs felt that spirituality did not belong in business. Table 5 illustrates responses.

---

Table 5 about here

---

Approximately 28% of the entrepreneurs felt spirituality was not valid in the workplace. However, it is interesting to note, the majority of the entrepreneurs said that spirituality is valid in the workplace if religion is removed. Many of the entrepreneurs were concerned about promoting religion in the workplace. Those who did think of spirituality as equating to religious beliefs were strident in their opposition to any sort of promotion of religion in the workplace. They felt that certain values, integrity, and character were important, but that each person should be allowed their own religious views. When spirituality was separated from religion and discussed as values or as ‘having a higher purpose in life,’ then most of the entrepreneurs saw a definite connection. Several said that something more than the quest for money was needed to drive the business or it became drudgery.

Definitions of spirituality by the entrepreneurs interviewed were wide-ranging. Samples of respondent comments included: “A higher purpose in life,” “. . . be true to yourself and lead by example,” “. . . discern your path, develop it, and enjoy it,” “. . . find our essence in love and the choices we make,” “. . . we are not alone,” “. . . give back to your community,” “. . . let go of the outcome and live in intention and love,” “. . . natural beauty of trees, light, and mountains,” “. . . integrity and character.”

These comments collectively form the definition of spirituality reflected by these entrepreneurs. Some were reluctant to connect spirituality to their work because to them, spirituality implied religion. They felt that a separation of business and religion is needed for fear of making employees uncomfortable. When religion was factored out of the discussion of spirituality many of the entrepreneurs felt that spirituality does have a place in business, but they may not actually call it spirituality.

### **Question 4: How do entrepreneurs view success?**

This question seeks entrepreneurs’ motivations by looking at how they perceive success. Is money the main motivator? Table 6 illustrates responses.

---

Table 6 about here

---

As popularly expressed in the literature, money alone was not the determining factor of the entrepreneurs' view of success. Only about 17% of the respondents thought that either 'money' or for that matter 'other factors' alone defined their success; whereas over half felt that the combination of these two themes came close to expressing their view of success. A variety of answers were provided to define 'other factors,' including, ". . . doing good work and keeping employees employed," ". . . doing good work or having a good reputation," and ". . . serving customers and employees well." Other expressions of success included, ". . . serving a need that had not been met before," ". . . helping people," and ". . . putting money back into the community." The entrepreneurs also took very seriously the fact that employees were relying on the business for personal income. One entrepreneur spoke of ". . . happiness in sharing the profits in good years. . . how several employees had amassed substantial sums in their profit-sharing accounts."

Therefore, money is important, but it is not the only indicator of success; other aspects such as meeting a need in a way that had not yet been done, creating a reputation, serving others, having clients return, being able to work with persons of choice, developing employees, and forging new relationships were also important. The entrepreneurs in this study have found a sense of self-control and self-determination that is fulfilling. They have made a personal connection with their staff, their clients, as well as the community. This connection, along with the financial rewards, translates to success.

### **Summary and Conclusions**

The study of entrepreneurs has been undertaken from numerous perspectives, but not in the context of spirituality. This qualitative study of entrepreneurs consisted of personal interviews with 29 entrepreneurs discussing their: motivation to start the business, definition of success, definition of spirituality, and perception of meaning and purpose in life. One purpose of this study was to add the entrepreneurial perspective to the current literature in the field of spirituality in the workplace and to explore entrepreneurs' motivations with regard to how their businesses may bring meaning and purpose to their lives. The respondent group of entrepreneurs were frequently influenced by family role models. Some aspects of previous careers were instrumental in the decision to start a business. Most entrepreneurs expressed some dissatisfaction with previous positions or bosses. They felt the job could be equally well performed, or even better on their own. The role of socioeconomic factors did not seem to be as strong as previous careers or family factors. Usually, entrepreneurs saw an opportunity and took the risk, figuring out how to solve problems along the way. Money was popular as a motivator, but was by no means a singular force. Other reasons included service to people, better working environment, and flexibility. The aspects of creativity, passion, and challenge were not expressed as main reasons. However, the motivation to start a business includes significantly more than just the expectation of monetary reward.

Personal values were expressed in terms of desiring better working environment or realizing the need for more control and independence. The entrepreneurs felt strongly about creating an environment where the reward was equivalent to effort, where fairness was maintained in dealing with employees and customers, and where one could choose with whom to do business. The freedom to control these factors improved personal relationships with clients and staff and allowed the entrepreneurs to live and work more closely in tune with the principles and values they thought were important.

Meaning and purpose for the interviewed entrepreneurs were realized through accomplishment, filling a need, and through the aspects of love, appreciation, and respect. The entrepreneurs were proud of their accomplishments. They believed that clients should be well served. Being in business is more than just about the money, it is about forming relationships. The belief that constituents should be treated well may come from previous careers lacking in human caring and fairness. Divergent beliefs with previous employers frequently influenced how these entrepreneurs run their own companies. The aspects of love, appreciation, and respect are important for employees, customers and other stakeholders. It is integrating these aspects of work that provides the basis for entrepreneurs to bring their whole *Self* into their work.

Spirituality in business is a personal concept for this group of entrepreneurs. Spirituality is a connection to something larger than themselves or their communities. It is about integrity and character and a sense of possibility. It was not about religion, although some entrepreneurs mentioned examples from the Bible as providing guidance in dealing with clients and staff. There was a concerted effort to keep religion out of the workplace. When spirituality was separated from religious beliefs and put in the context of values or higher purpose, most of the entrepreneurs felt that there was a connection between spirituality and business.

### **Recommendations for Future Research**

This groundbreaking research provides the researchers with at least two areas to explore in the future: targeting the intangible motivating factors for starting a business; and focusing on the spiritual aspects of individual growth and development of entrepreneurs. In addition, a larger group of entrepreneurs could be used in the next project. The sample of this study is one of convenience and may be self-selecting. It is possible that these entrepreneurs were interested in this subject and agreed to be interviewed. It would be interesting to find a group of entrepreneurs, such as in an organization, and use statistical sampling methods in the methodology. Research targeting the intangible motivators of starting a business has not been undertaken as much as research targeting the effects of family, previous careers, and socioeconomic factors. An in-depth study targeting the themes of service to people, passion, challenge, creativity, independence, and autonomy as motivation for starting a business would broaden understanding of motivation. Research on this topic would be of value to educators who seek to understand why entrepreneurs start businesses and how to train the next generation of entrepreneurs.

The spiritual aspects of individual growth and development of entrepreneurs in the process of starting and growing a business is an interesting idea. A research study could look at entrepreneurs from the standpoint of personal growth. Personal growth could include growth in the areas of emotional intelligence, individuation, or spiritual growth. This work would again further the study of entrepreneurs as well as the literature on spirituality in business and leadership in business.

## CONTINUOUS IMPROVEMENT IN SMALL BEER DISTRIBUTION BUSINESSES.

Timothy P. Keane

timothy.keane@rockhurst.edu

### **EXTENDED ABSTRACT**

Convulsive change in the beer industry over the past two decades has created an increasingly complex operating environment for its distributors. From a supply chain perspective, the three tier distribution system in the beer industry (Brewer → Distributor → Retailer) is structured to focus the distribution link on marketing and delivering beer to licensed retailers for sale to consumers. As the major brewers have expanded their product offerings in an effort to increase sales, they have also been consolidating their operations and distribution network with the goal of improved productivity. Consolidation initiated by the brewers has reduced the number of beer distributors by nearly fifty percent in the past twenty years. While the number of beer distributors has decreased, their retail customer base has expanded dramatically in both total number of outlets as well as type, with the introduction of new store formats such as convenience stores, mass merchandisers and gas/oil retailers.

This research examined the multitude of issues facing small beer distributors operating as the critical link between two powerful supply chain partners, each with demands and expectations that often conflict with the beer distributor's own goals. Beginning with an electronic survey to validate the highest priority issues, the research drilled down into a key operational concern that appeared to be widespread. With the expanded product offerings from the brewers, today's beer distributor is challenged to effectively sell a product portfolio nearly ten times greater than twenty years ago to a larger and more powerful retail customer base. Most beer distributors attempt to employ some comprehensive retail sales and marketing process designed to increase the sales and profitability of their product portfolio. The process generally includes a pay for performance program for the sales force that targets retail account objectives, such as new product placements or selling the retailer on a sales promotion program. Considering that each sales rep calls on an average of ten retailers each day, it is not inconceivable that the rep may have dozens of pay for performance objectives to achieve every single day.

Research results from beer distributors across the country indicated that the logistics of managing their pay for performance program can be overwhelming. Additionally, in many beer distributors there does not appear to be any evaluation and control process for measuring the effectiveness of their program. For example, when distributors focus pay for performance objectives on new product distribution and volume increases, they rarely evaluate the profitability impact of accomplishing those objectives. If the distributor does not establish and reward complementary objectives focused on product rationalization and profitability, the result often translates to higher costs in the form of finished product loss and missed sales due to out of stocks. This research revealed examples of finished product losses costing distributors up to \$700,000 a year, depending on size and type of program implemented.

# Perceived barriers to entry: Is there any difference between Small, Medium-Sized and Large companies?

## Abstract

The objective of this paper is to provide some empirical evidence about the importance of barriers to entry. In particular, the perceptions of firms are considered. Three questions are raised: Which entry-barriers are important in the perception of firms in the Dutch economy? Do these perceptions differ between sectors? Do these perceptions differ between small and large firms? It is shown that the procurement of a viable sales volume, access to capital and financial risk, are considered to be the major barriers. The ranking of the importance of specific barriers to entry coheres among the sectors under study. The most remarkable result is that the figures indicate that micro firms perceive lower barriers to entry than medium-sized and large firms.

## 1. Introduction<sup>i</sup>

Entry of new competitors into the market is generally approved from an economic point of view. It is expected to create employment and to foster the dynamics in an industry. New competitors play an equilibrating function, as firms will enter the market if profits are above the long-run competitive level. As a result of entry, profits would decrease to the long-run equilibrium level. Entrants are also considered as important agents of change, as new firms may introduce new products or production processes. The upshot is that entry contributes to allocative as well as dynamic efficiency in the market (Audretsch and Thurik, 2001). However, several mechanisms can prevent firms from entering the market and, consequently, hamper the process of allocative and dynamic efficiency. In line with this perspective it is easily understood that barriers to entry constitute an important issue in competition policy.

In a previous EIM report the results of a comprehensive literature study on entry-barriers have been published (Blees *et al.*, 2003): the theoretical background and the operating mechanisms are discussed. The report describes in total 37 structural and strategic barriers to entry and discusses the expected specific effects on small businesses. The literature study concludes that SMEs suffer more from barriers to entry than large companies (often existing companies active in another product or geographical market). For example, it is argued that barriers related to advertising, brand name, capital requirements, cost of operating abroad, high wages, R&D and selling expenses are less relevant for large firms. Large companies are expected to be able to solve these problems more easily as they have better access to distribution channels, financial capital, and they have more organizational and technological experience (see also Golodner, 2001; Fotopoulos and Spence, 1998; Acs and Audretsch, 1989). Remarkably, most literature addresses the consequences of barriers to entry for large firms while most entrants are SMEs.

The present paper is the result of a follow-up study and aims at addressing empirically the question whether small firms in the Dutch economy face more and different barriers to entry than large companies? Several authors stress the need for empirical evidence on extant barriers to entry (Scherer, 1989; Geroski *et al.*, 1990; Bunch and Smiley, 1992; Karakaya, 2002). The literature study (Blees *et al.*, 2003) interprets the mechanisms of each barrier and discusses whether the barrier constitutes a specific hurdle for SMEs. From a theoretical perspective it is concluded that several barriers affect the smaller firms differently. However, this does not necessarily mean that the problem is widespread, nor does it measure to what extent the problem is perceived by small firms. The present study wants to shed some light on the latter issue and, in particular, verify whether the perceptions differ between small and large businesses. It is expected that small companies will emphasise the importance of barriers to entry that constitute a problem especially for SMEs. The relevance of this approach is discussed by Singh *et al.* (1998: 230). They observe that many theoretical models exist but that empirical evidence in support of these models is rather weak. Subsequently, they raise the question: 'how important empirically are the types of strategic behaviour, which have been modelled [theoretically] so copiously?'.

From a policy perspective this is a relevant issue as entrepreneurship and new ventures are encouraged to reduce unemployment and to increase the dynamics in the economy. The existence of entry-barriers is a potential threat for the effectiveness of these policies. In the Netherlands several policy changes are debated and some have been implemented to reduce the barriers to entry start-ups were facing as a result of existing rules and regulations (licences, diploma's).

This leads to the following research questions:

1. Which entry-barriers are important in the perception of firms in the Dutch economy?
2. Do these perceptions differ between sectors?
3. Do these perceptions differ between small and large firms?

The next Section starts with a concise overview of the literature on entry-barriers. The concept is defined and the method to measure the importance of entry-barriers is discussed. Subsequently the sample and the questionnaire are presented. In total 1170

Dutch firms have been interviewed. Section 4 discusses the empirical findings. Finally conclusions and recommendations for further research are made.

## 2. Literature review

A large body of literature discusses the importance of entry-barriers. Two different traditions can be distinguished: industrial organization (e.g. Bain, 1956; Stigler, 1968; Von Weizsacker, 1980) and strategic management (e.g. Porter 1980, 1985; Singh *et al.*, 1998, Robinson *et al.*, 2001). The first tradition focuses on the industry as the unit of analysis, strives for efficiency and identifies harmful barriers for economic development. Various models are developed to show how entry-barriers affect the behaviour of firms and the performance of the industry. One of the main issues concerns the question whether government policy is needed to neutralise the effects of the barriers. The second tradition takes the firm as the unit of analysis and assesses entry-barriers as a resource to create competitive advantage for individual firms. In line with this approach superior strategies should create sustainable competitive advantage. In other words, a firm should make use of entry-barriers that deter new competitors in the firm's market.

The contradictory assessment of the value of barriers to entry is related to the unit of analysis and the role competition is expected to play in the two traditions. At the firm level it is indeed important to develop resources that are difficult to copy by competitors (Rangone, 1999; Barney, 1991). A reduction of competitive forces is generally in the interest of incumbent firms. However, from a welfare economic point of view, this should not lead to social costs, as a reduction of competitive forces may hamper the allocative and dynamic efficiency of the industry. The latter argument is put forward by Von Weizsacker (1980) to justify public policies. This study does not focus on the role of competition and the assessment of social costs. The objective of this research is to identify important entry-barriers perceived by firms (Yip, 1982; Karakaya and Stahl, 1989; Singh *et al.*, 1998; Smiley, 1988). It aims at recognising the major constraints that hamper firms in making their entry decision. The unit of analysis is the firm.

In line with the two traditions, two types of barriers can be distinguished: structural and strategic barriers to entry. The structural barriers stem from market structure characteristics and are widely discussed in the tradition of industrial organisation. Bain (1956) introduced the concept of 'barriers to new competition'. The concept is based on the assumption that competition is key in the operation of industries and that any artificial barrier to competition may reduce the efficient allocation of resources in the industry. Bain stressed the importance of structural characteristics that hamper market entry of potential competitors: economies of scale, technological advantages, absolute cost advantages, etc<sup>ii</sup>. The conclusion of this research is that entry-deterrent mechanisms limit the intensity of competition and may enable incumbent firms to raise prices and to realise supernormal profits. The Chicago School (Stigler, 1968) contributed to the debate on barriers to entry by stressing the importance of costs asymmetry between incumbents and potential entrants: The research should not focus on supernormal profits but on the question whether the conditions of entry for the incumbents were less difficult than for the new entrants. The importance of this argument becomes clear when the advantages of economies of scale are interpreted.

According to the Chicago School, scale economies do not represent a barrier to entry if they imply penalties for companies operating at sub-optimal levels of production. A third approach that stems from this tradition focuses on the welfare effects and defines barriers to entry as a difference in cost structures which provokes a distortion in the use of economic resources from a social point of view (Von Weiszacker, cited in Geroski *et al.*, 1990: 10). Each approach has its specific difficulties. These are beyond the scope of this paper and will not be discussed. However, what is important is to understand that the different approaches lead to different definitions of entry-barriers. We conclude that Bain's perspective provides the broadest scope, while the other two approaches consider additional requirements in order to identify the 'real' barriers that hamper the efficient allocation of resources in the economy.

The strategic management tradition stresses the importance of strategic barriers. Barriers to entry do not only result from structural characteristics of the market but they are created as a result of strategies of individual firms that reduce the threat of new entrants. Following Barney (1991), firms are advised to 'obtain sustained competitive advantages by implementing strategies that exploit their internal strengths, through responding to environmental opportunities, while neutralizing external threats and avoiding internal weaknesses'. Porter (1980: 9-13) does not define the concept but specifies seven major sources of barriers to entry: Economies of Scale, Product Differentiation, Capital Requirements, Switching Costs, Access to Distribution Channels, Cost Disadvantages Independent of Scale and Government Policy. Implicitly he uses a broad definition for barriers to entry in order to encompass the barriers that result from strategic behaviour. He provides a kind of typology of barriers to entry that firms should take into account when their competitive strategy is developed. Porter's specification also shows that structural and strategic barriers are related. The barrier may be rooted in the market structure, but this will not discourage firms to react to this characteristic strategically. The upshot is that most structural barriers have a strategic component too. For example, advertising can be considered as a structural phenomenon in the automobile industry, however, each actor develops its own advertising strategy (brand) that may affect new competitors.

Fotopoulos and Spence (1998) have shown that barriers to entry are not independent from size: 'Some limited evidence is offered that small firms are different in that they manage to overcome entry barriers, perhaps adopting different survival strategies, and that large firms are well aware of market conditions and are in an advantageous position to overcome many of the problems. Size classes in the middle of the distribution offer rather mixed results due to size-related advantages and disadvantages' (*ibid.*, p. 141-142). Consequently, some barriers to entry pose a higher obstacle for SMEs entering a new market than they do for larger firms. In their literature study on barriers to entry, Blees *et al.* (2003) concluded that small firms are more vulnerable than large firms: about half of the barriers constitute a specific hurdle for SMEs. Large entrants are expected to take advantage of business activities in other industries and their large experience with organisational and technological issues; their well-established relationships with suppliers, customers, and distribution networks; and their easier access to financial capital or cash flow. Moreover, it is usually easier for larger companies to profit from *economies of scale and scope* and to counter the incumbents' *advertising and selling expenses*.

The report also observes that some barriers to entry may apply specifically to large firms. *(Dynamic) Limit-pricing, excess capacity* and *(anticipated) retaliation by incumbents* are expected to pose a relatively high barrier to larger entrants. Small entrants are usually unable to influence total supply and to induce a serious market price reduction. Incumbents will not react to such entrants and may even not observe them. Large entrants do influence total supply and will expect reactions of incumbents. Thus, large firms can anticipate a higher barrier in this respect than smaller entrants.

### **3. Definition of concepts and data collection**

In line with the broad perspective of this research we used the following definition of barriers to entry: “*all advantages of established sellers in an industry over potential entrant sellers, as perceived by firms which seek to enter a new market*”. The focus is on the perception of firms and on entry to a new market. We prefer the concept ‘market’ to ‘industry’. According to Ferguson (1992: 32) markets group together firms producing close substitutes from the buyers point of view, while an industry groups together close substitutes from the suppliers point of view. These are usually broader groupings than markets. The advantage of the market concept is that it has a clearer meaning for the interviewed firm. Small firms operating in a specific niche do not always have an idea about the potential new competitors for the industry but they have a good overview of potential new competitors in the market in which they are active.

The distinction between small and large is of special interest for this study. Defining the size of the firm is not straightforward. Several criteria may serve as a yardstick. Most authors conclude that a mix of criteria would result in the best classification, e.g. employment, type of ownership, invested capital (Storey, 1994). The problem is that a sophisticated classification is difficult to apply in practice as proper information about the used criteria is not easily available. Therefore, most authors use one simple criterion: the number of full-time employees. In the report we applied the following classification: micro enterprises < 10 employees (MI), small enterprises 10-<50 (SM), medium and large enterprises 50+ employees (ME).

A large number of structural and strategic barriers to entry were presented in the questionnaire (see annex 1). However, not all the barriers identified in the literature study (Blees, *et al.*, 2003) were addressed. Most important were time limitations. On the basis of previous experiences we decided that the total interview by telephone should not take more than 15 minutes. Some issues were difficult to describe in an unambiguous question (e.g. causal ambiguity). Other barriers to entry were covered by the answers on similar barriers (brand name and customer loyalty are part of advertising, experience advantages are related to cost advantages, government policies are related to government licences, know how is related to level of technology and patents).

Some aspects were covered by two separate questions in order to be able to make a distinction between the importance of structural characteristics and behavioural characteristics. For example, with regard to advertising we presented two statements:

1. Firms in the market have high expenditures for advertising and promotion

(structural), 2. The products are heavily supported by advertisement and promotion in order to make entry to the market less attractive for new competitors (strategic). We claim that the listed barriers to entry in Annex 1 give an overview of the most important barriers discussed in the extant literature. Some of these barriers are branded as they are expected to raise a specific hurdle for SMEs.

Incumbent companies were asked to indicate on a five point Likert scale to what extent new competitors would encounter the barrier in question<sup>iii</sup>. Ideally the survey should have addressed new and potential competitors<sup>iv</sup>. However, potential newcomers are difficult to identify and, therefore, we decided to interview incumbents. As we are interested in barriers (potential) entrants may face and not the behaviour of the specific incumbents per se, the questions were directed at practices in the industry rather than the firm's specific behaviour. In general, the incumbents were asked to indicate how important a specific barrier is if a comparable company (same size) wants to enter the major product market in which the incumbent is operational. As barriers to entry are related to product markets and most firms manage multi-product operations, we explicitly referred to the most important product market. The advantage of this format for the question is that all companies have experience with the market and, therefore, are able to value the importance of the specific barrier.

As the concepts involved are sometimes difficult to circumscribe in unambiguous questions a pilot study has been carried out in November 2004, in which 40 students participated. The students tested the survey and were asked to write about 100 case studies of the companies they interviewed. The case studies have allowed us to grasp the functioning of the perceived barriers to entry in the different industries under study and, therefore, have facilitated the interpretation of the results of the questionnaire. Moreover, some questions were refined to avoid ambiguous interpretations. The final questionnaire was pre-tested by telephone with potential respondents.

The sample consists of 1,170 Dutch firms in six industries, i.e. furniture, employment agencies, chemical industry, ICT, food (production of bread) and retail (clothing and shoes). The aim was to collect data for approximately 175-200 firms per sector divided over three size categories (< 10 employees, 10 to < 50 employees, and 50+ employees). Per size category, the firms were selected at random from the Direct Marketing CD-database of MarketSelect<sup>v</sup>. Especially in the size category of 50+ employees, in some sectors, all existing firms were contacted because of the limited number of firms with over 50 employees.

In total 3,562 firms were contacted for the telephone survey. This resulted in 1,074 completed responses: a response rate of 30%. Of the contacted firms, 33% refused to cooperate. Another 24% of the contacted firms could not be reached because of an answering machine, get no answer, number engaged or more than 6 attempts with no response. Finally, with 13% of the contacted firms an appointment was made but it did not result in a completed questionnaire because the targeted sample was reached. The other 96 respondents were interviewed by our students in the pilot phase<sup>vi</sup>.

The MarketSelect database was used to test for non-response bias. Smaller firms were more willing to participate in the research than large firms. This holds for the total sample as well as for the sectors furniture, employment agencies, chemical industry

and ICT. No significant differences related to size were found for the food industry and retail. In the food industry, firms were less willing to participate in the research compared to the other sectors, probably because of the Christmas rush.

#### 4. Results

In Table 1 the number of observations per industry and per size class are presented. Most observations are in the class of < 10 employees, or micro firms. In retail, we only have five observations of firms with 50 employees or more. As the sample was drawn from a database including subsidiaries and branches of larger firms, and responses were provided by local managers, the questions concern employment figures of the selected subsidiary. About 40% of the interviewed establishments are related to a larger company.

Table 1 about here

In Table 2 the perceived barriers are presented. Overall, securing input, collusion, knowledge, retaliation and strategic knowledge protection are the least important barriers. According to the interviewed firms most barriers concern unimportant constraints (value lower than 3)<sup>vii</sup>. This can be interpreted as a good sign for the Dutch economy as competitive forces seem to be operational. Remarkably, some of the interviewed managers/owners raised the question why we were bothering about these issues, as solving these problems was considered to be their key competency. However, it is noted that only incumbents were interviewed, which may lead to a certain bias as these firms have surmounted existing barriers. Knowing how to solve a problem makes the problem trivial. To counter this argument it may be stated that only incumbents should be interviewed, as only the opinion of viable firms has to be taken into account.

In general the ranking of the importance of specific barriers to entry coheres between the sectors: securing input and collusion are of minor importance for all but two sectors (respectively retail and employment agencies), while sales volume and capital are most important for all sectors. However, for all barriers some significant sectoral differences are observed at the 5% level, except for sales volume, which is significant at the 10% level. For instance, securing input is relatively important in retail and knowledge is relatively important in the chemical industry. In the last column of table 2 the significant differences are presented.

The most important barrier is the procurement of a viable sales volume. The average value attached to this barrier is significantly higher than the average value for other barriers. It may be argued that this high value results from the cumulative effect of all kinds of other (strategic) barriers (collusion, retaliation, limit pricing, switching costs). However, the values given to these specific entry barriers were significantly lower than the importance given to sales volume. This indicates that the problem is more related to the operation of normal competitive processes and, subsequently, that the requirements for successful entry (and survival) are not easy to meet. Moreover, the procurement of a viable sales volume is also related to survival once entered, which is strongly influenced by the unknown reaction of incumbents.

Other important barriers are cost disadvantages, strategic behaviour related to differentiation and financial risk. Two sectors, employment agencies and ICT, have relatively low scores, whereas the food industry shows the highest scores on these barriers. Overall, the firms value only a few barriers as important constraints. Finance and sales volume are key issues in all sectors. The ICT and furniture industry are sectors with relatively low barriers, the chemical, retail and food industry show relatively high values for the barriers under consideration.

Table 2 about here

The importance of the majority of barriers does not differ significantly between firms of different size. However, for collusion, knowledge, retaliation, switching costs, strategic behaviour related to R&D, government policy, excess capacity, economies of scale, and strategic behaviour related to differentiation, some significant differences are observed between firms of different size (5% level).

The excess capacity barrier is more important in the perception of medium-sized firms than for micro and small firms. In a market with excess capacity, it will be more difficult for a relatively large firm to enter because it brings considerable extra capacity to the market. This finding confirms the difference that is made in theory between small-scale and large-scale entry. The barrier related to collusion is somewhat higher for micro firms. However, we note that even the average value of micro firms for the importance of this barrier is low. All other barriers, with significant differences between firm size classes, indicate that micro firms give lower values than medium and large firms. Also the value given to the most important barrier (sales volume) is lower than the value given by medium and large firms. The upshot is that, on average, micro firms perceive lower barriers to entry than medium-sized and large firms.

Table 3 about here

## 5. Conclusions

The question raised by Singh *et al.* (1998) regarding the need for empirical evidence about the importance of entry barriers is highly relevant. Some issues seem to be purely based on theory, however, other barriers play a role in the real business world and need proper attention of policy makers.

The most important barriers are rooted in characteristics of the market structure: sales volume, capital, financial risks, cost disadvantages, costs of capital, economies of scale. Only one of the major barriers stems from strategic behaviour: behaviour with regard to differentiation.

Some differences between sectors are observed. However, in general, the ranking of the importance of specific barriers to entry coheres. This indicates that the differences between firms are not primarily explained by differences between sectors.

Interestingly, our results reject most expectations formulated in the literature study (Blees *et al.*, 2003). The results of the survey show that the importance of barriers to entry like access to distribution channels, advertising, capital requirements and R&D is not significantly higher valued by smaller companies. Two barriers (economies of scale and product differentiation) were expected to be a specific hurdle for small firms but our results indicate that in particular larger firms perceive these problems. A possible explanation for this result is that small firms are 'less punished' if they produce on a small scale, or specialize at specific market niches. Larger entrants may have to produce the whole range of products/services to serve the market properly.

What does this mean for policy? Financial issues seem to be key and, therefore, policy should address in particular the functioning of the financial market. No indication is found that specific policies are needed for SMEs. On the contrary, more attention should be given to larger entrants as they will have a more dramatic impact on the competitive processes in the market.

## Endnotes

---

- <sup>i</sup> These are the views of the authors and need not reflect those of EIM. We would like to thank all students who participated in the fieldwork and the course 'Small Business Economics'. Their reports, enthusiasm and critical comments were highly appreciated.
- <sup>ii</sup> The emphasis of Bain on market structure has been criticized within the discipline of Industrial Organisation. By the late 1970s these views became known as the 'The New Industrial Organisation' (Geroski *et al.*, 1990). They stressed the importance of behavior as a determinant for market performance and market structure (in the long run). The approach comes close to the tradition of strategic management as behavioral aspects are considered to be key. However, in line with the tradition of Industrial Organisation, the unit of analysis is the industry.
- <sup>iii</sup> The reply options were: not at all, nearly not, somewhat, to a large extent, to a very large extent (or alternatively: strongly disagree, disagree, not agree/disagree, agree, strongly agree).
- <sup>iv</sup> Even the group of new and potential competitors can be considered as too broad. For the research information from the 'marginal entrant' is needed. This marginal firm is indeed difficult to identify.
- <sup>v</sup> The database is based on information on business registrations by the Chambers of commerce, address information by TPG Post and checks by MarketSelect.
- <sup>vi</sup> For most barriers, no significant differences were found between the data from the telephonic interview and the students' interviews. Therefore, pooling the data is admissible.
- <sup>vii</sup> The scores have the same range as previous research, see e.g. Smiley (1988) and Karakaya (2002).

## **ETHICAL ENTREPRENEURS: AN OXYMORON?**

### **ABSTRACT**

This paper presents the results of a survey of early-stage incubator sited entrepreneurial firms. Firms were asked about their views on ethics and the ethical climate of their organizations. Results indicated that respondents tend to think of themselves as ethical and do not feel they must sacrifice their ethics to succeed in their ventures. The results also show that most early-stage entrepreneurs have a code of ethics that is communicated to employees. Contrary to anecdotal and theoretical suggestions that entrepreneurs are by nature more likely to “bend rules” and act unethically, these results lend support to studies that have found that entrepreneurs are more ethical.

### **INTRODUCTION**

Are entrepreneurs ethically different from others to the extent that one can consider the phrase "ethical entrepreneur" an oxymoron? Do the demands of the entrepreneurial business, with its risk and profit expectations, create circumstances where conducting oneself in an ethical manner

is difficult? Anecdotal evidence abounds about the unethical nature of entrepreneurs. Very recently a telecommunications entrepreneur was arrested and charged with the largest criminal case of tax evasion ever brought; he allegedly hid over \$450 million in income (Johnston, 2005).

Since entrepreneurs first began generating new ideas and attempting to take them to market, these innovators have been praised for their contributions and criticized for acting unethically (Hannafey, 2003). Because entrepreneurs are thought to think “outside the normal box” in creating the innovations that make them entrepreneurs, it is thought that they also act outside the normal box as well. Terry (1993), for example, said that entrepreneurship implies a mindless disrespect for tradition. Much earlier Fisher (1983) argued that entrepreneurs work at the edges of society, not the mainstream.

The research literature in entrepreneurship and ethics presents the same contradictory picture. Reasons are suggested as to why entrepreneurs are unethical, but empirical work suggests that entrepreneurs think of themselves as highly ethical. Discussing the moral reasoning skills of entrepreneurs, Teal & Carroll (1999) expressed a view that entrepreneurs may be seen as rejecting the norms of society, but the results of their study suggest "that entrepreneurs as a group may exhibit higher levels of moral reasoning skill" (p. 238). Taking an historical perspective, Timmons & Spinelli (2004), stated, "A touch of suspicion still tinges entrepreneurial activity, and the word entrepreneur may still connote to some a person who belongs to a ruthless, scheming group located a good deal lower than the angels" (p. 334). They also state, however, that "successful entrepreneurs believe that high ethical standards and integrity are exceptionally important to long term success" (p. 332).

## **BACKGROUND**

As noted above, entrepreneurs may not always be viewed in a positive light. While that perception may result from stereotypes of the past, entrepreneurs--regardless of actions--have a tough road ahead of them given the stereotypes. High ethical standards have been identified as essential to long term success (Timmons & Spinelli, 2004), so the entrepreneur must and should demonstrate ethical behavior. The first need, then, for this discussion is to determine why these negative perceptions about entrepreneurial behavior have developed in the broad public.

Some researchers have identified cognitive sources for unethical activity on the part of entrepreneurs. Specifically, the demands of time and money under conditions of severe uncertainty as to outcome are thought to create cognitive pressures that lead entrepreneurs to take shortcuts (Baron, 2000; Timmons & Spinelli, 2004), especially in the early stages of the entrepreneurial activity (Fassin, 2000; Morris et al., 2002). Others are noted below.

### **Age and Firm Size**

In his review of the ethics and entrepreneurship literature, Hannafey (2003) noted that because of the need to work long hours, often in isolation from others, there is little time for entrepreneurs to reflect upon the decision they are making, a situational factor that can lead to less ethical behavior. Other researchers have looked at the characteristics of the new venture creation process and found certain characteristics of that process (external time pressures, scarce resources, competition) as situational sources of the pressures that act upon the entrepreneurs' cognitive ethical abilities (Chau & Siu, 2000). These situational factors that lead to cognitive

ethical failures should be more severe in the early stages of the life of the entrepreneurial venture. Further, the larger the company, the less isolated the entrepreneur would be and the more able to share workloads, thus the cognitive ethical failures likely should be more severe the smaller the firm size.

From this literature evolve the first two null hypotheses for this study:

*Hypothesis 1:* There is no difference in the ethical behavior of entrepreneurs related to the age of the enterprise.

*Hypothesis 2:* There is no difference in the ethical behavior of entrepreneurs related to the size of the firm.

### **Entrepreneurial Characteristics**

In addition to situational factors such as age and size of the enterprise, researchers have studied personal characteristics of the entrepreneur used to explain perceived differences in ethical behavior of entrepreneurs and managers. DeLeon (1996) discusses some of the virtues and vices of entrepreneurs. Virtues are defined as innovation, go-after-it attitude and risk taking. DeLeon defines the following characteristics for the entrepreneur: egotism, selfishness, waywardness, domination and opportunism. Each of these characteristics is seen as necessary and not necessarily negative. Longenecker et al. (1988) located entrepreneurial ethics in the individualism that characterizes entrepreneurs (as does deLeon [1996]). Others pointed to the bias for action that they believe characterizes entrepreneurs as sources of unethical behaviors

(Bhide, 1996). Bucar & Hisrich (2001) discussed the independent, self-centered focus that entrepreneurs bring to business as a characteristic that differentiates entrepreneurial ethics from managerial ethics. They suggested, however, that this focus leads to more ethical behavior on the part of entrepreneurs because entrepreneurs identify with their firm to a greater extent than managers do. Bucar & Hisrich (2001) drew this conclusion: "Entrepreneurs consistently demonstrated higher ethical attitudes in the internal dealings of the company" (p. 78).

These individual characteristics show no consistent affect on entrepreneurial ethics in the studies that have been performed. However, when combined with entrepreneurs' perceptions about the impacts of their activities on society, an explanation for the inconsistencies in the literature might be forthcoming. As stated earlier, entrepreneurs may not be perceived in a positive light because of the history of entrepreneurs in the United States. Newbert (2003), however, discusses today's entrepreneur in a very positive way. Newbert states that "for the majority of today's entrepreneurs, the pursuit of material wealth is generally not the dominant motivational force behind the decision to start a new business" (p. 255). The entrepreneur can not be solely invested in economic self-interest. For success, the entrepreneur must look beyond self-interest. Miles et al. (2004) stated that in free societies, entrepreneurial activities result in enhanced social welfare due to the innovations entrepreneurship brings to society. This is echoed in other studies that note the positive economic effects of entrepreneurship (Hannafey, 2003).

Given the historical stereotypes and Newbert's statements regarding today's entrepreneurs, it appears that interesting ethical challenges face an entrepreneur. Morris et al. (2002) goes on to say "entrepreneurial behavior is a set of actions fraught with ethical dilemmas. Entrepreneurs are

often admired for the creative ways in which they overcome significant limitations, obstacles and sources of resistance to their new venture ideas" (p. 334).

It may be that the entrepreneur, when viewed from the outside, appears to be acting selfishly, without regard to societal rules, and in other ways behaving in a manner that society might deem to be unethical. However, the entrepreneur's personal perspective may be that the actions that are being taken are in service to the betterment of society and are ethical just for that reason. This would suggest that entrepreneurs reason differently about ethics than managers or other individuals.

Thus our null hypothesis with respect to the personal characteristics of entrepreneurs is:

*Hypothesis 3: Entrepreneurs do not view themselves as ethical.*

### **Organization Issues**

A related factor is often discussed in the entrepreneurial ethics literature and concerns the types of organizations that entrepreneurs develop (Hannafey, 2003). An organization may be characterized according to its ethical climate. The ethical climate of an organization is developed over time and consists of a set of shared values about the nature of the organization and its goals. Recall that many researchers theorize that entrepreneurial ventures are unique in their level of stress and the volatility of their business environments (Hannafey, 2003). In the early stages of venture creation, the ethical climate is likely to depend solely on the ethical behavior of the entrepreneur. As the organizations grow in size and age, the ethical climate may change (Morris et al., 2002). Morris et al. (2002) found that while firm size and age were not associated with

whether firms were exemplary or deficient in their ethical behaviors, one factor, the extent to which formal management systems were in place, was a good predictor of ethical behavior. It can be argued, however, that these formal management systems are more likely to be in place in older firms, unless the founding entrepreneur explicitly set a solid moral tone in the firm from the beginning as the result of personal vision (deLeon, 1996). In that case, it would be expected that the entrepreneur's personal ethics would be the same as those of the firm and further, that those ethical values would be formalized in the firm, in the form of ethical codes.

This leads to the fourth null hypothesis:

*Hypothesis 4:* There is no relationship between entrepreneurial firms with positive ethical climates and their established codes of ethics.

### **THIS PAPER**

Given this contradiction in perception and research findings, the present study seeks to add to the ethics and entrepreneurship bodies of knowledge by conducting a survey of technology-based firms housed in business incubators to determine their views on ethics. This research differs from earlier research in using a narrower definition of entrepreneur that captures the distinctions between true entrepreneurial work and small business management that drive the conceptual but not the empirical literature. Longenecker et al.(1988), for example, included all self-employed individuals and small business owners in their study of entrepreneurial ethics. Teal & Carroll (1999) define the entrepreneur as someone who establishes and manages a business for profit and growth. But more recent research utilizes Drucker's definition of the entrepreneur as someone who "searches for change, responds to it, and exploits it as an opportunity" (1985, p. 28; see also

Brenkert, 2002). The true entrepreneur takes the old and changes it, or creates the new, paralleling Schumpeter's (1950) original "creativity" definition. Entrepreneurs take greater risks than managers and small business owners. These risks bring the potential for a larger range of unethical actions in pursuit of the opportunity. It is necessary, therefore, to distinguish the entrepreneur from both the manager and the small business owner to understand and distinguish the ethical behavior of all of these groups.

## **METHODOLOGY**

### **Sample**

A random telephone survey of 79 technology-based firms was conducted. All firms were US-based and housed in US technology-based incubators. By definition, then, these firms were entrepreneurial.

### **Instrument**

The survey was written and conducted in three parts: general firm information, an ethics survey, and a Sarbanes-Oxley survey. All respondents were asked to complete all sections during the telephone interview. Survey questions included demographic information; a series of yes/no questions; and a series of Likert scale questions. Survey questions were drawn from the literature on entrepreneurial ethics. Specifically, several survey questions were taken from Bucar & Hisrich's (2001) study comparing entrepreneurs and managers.

Some of the questions used were designed to establish the personal attitude of the entrepreneur about ethical behavior. For example: “People are basically good;” “People act honestly;” and “Illegal acts are ethically wrong” are questions that establish ethical expectations about people and can be interpreted to be self-characterizations. These questions served as proxies for the ethics of the entrepreneur.

To distinguish these personal attitudes about ethical behavior from expectations of business behavior, questions such as “When working with other firms we have been dealt with fairly;” “Our personal ethics are sacrificed to the goals of the business;” and “I have conflicts when it comes to personal versus business decisions” were included. These distinguishing questions were also used as proxies for ethical behavior in business. Entrepreneurs who agreed with the last two questions would be thought to act less ethically than would those who disagreed.

The survey also included a series of questions concerning the firm’s ethical climate. Yes/no questions included “Have you ever taken a course/seminar in ethics?”; “Does your firm have a written code of ethics?”; “If no, does it have an unwritten code?”; and “How is your firm’s code of ethics communicated to employees?” (answer choices were “verbal”, “written”, or “by example”). Finally, the survey asked for disagreement/agreement with the statement on a six-point Likert scale, “Our code of ethics is used in decision-making.” See Table 1.

## Hypotheses

*Hypothesis 1:* There is no difference in the ethical behavior of entrepreneurs due to the age of the enterprise.

*Hypothesis 2:* There is no difference in the ethical behavior of entrepreneurs due to the size of the firm.

To test these hypotheses regarding firm, age and size the following questions were means tested across the two groups:

- My personal ethics are sacrificed to the goals of the business.
- When working with other firms we have been dealt with fairly.
- Trying to respond to a variety of stakeholders produces conflicts.
- I have conflicts when it comes to personal versus business decisions

*Hypothesis 3:* Entrepreneurs do not view themselves as ethical.

To test this hypothesis, that relates to the individual entrepreneur, and his view of others, the following questions were means tested across the sets of groups, i.e., by age and size.

- People are basically good.
- People act honestly.
- Some people are hard to work with because of ethics
- Illegal acts are ethically wrong.

*Hypothesis 4:* There is no relationship between entrepreneurial firms with positive ethical climates and their established codes of ethics.

To test this hypothesis, the following variables were means tested across both groups, i.e., by firm age and size and whether a written or unwritten code existed. Further, if a firm had no written code of ethics, the variables were again run by age and size against how the firms' code of ethics was communicated.

- Does your firm have a written code of ethics?
- How is your firm's code of

ethics communicated to  
employees?

- Our code of ethics is used  
in decision making.
- Trying to respond to a  
variety of stakeholders  
produces conflicts.
- I have conflicts when it  
comes to personal versus  
business decisions

### **Comments on Methodology**

The original data set had seventy-nine firms, with the size of respondent firms as measured by employee numbers ranging from one to 285 employees. The average firm size was 8.99 employees (sd 9.22) and the outlier with 285 employees was removed from the data set. The total number of firms remaining was seventy-four. The firms were then split for analysis using the mean, with 68% of the firms smaller than 8.99 employees. While one could argue that the firms should have been split so both groups were equal, the frequencies of firm sizes did not allow for that.

The original data set then had firms ranging in age from one to thirty-eight years old, with an outlier of thirty-eight years. With the outlier removed, the firms' average age was 4.76 (sd 3.44).

The

firms were split for analyses at an age of five and 72.4% of the firms were five years or less in age. Again, one could argue that the firms should have been split so both groups were equal. The frequencies of the firm ages did not allow for that.

Graduate research assistants performed the surveys. One of them commented that he doubted that respondents would tell him they were not ethical. Perhaps one reason for a disparity in the literature about the lack of ethics among entrepreneurs and survey results, anonymous or not, may be the social desirability bias. Fernandes & Randall (1992) found that some form of social desirability bias was detected in over half of the ethics relationships they studied. They also noted that the bias is more prevalent when attitudes rather than behavior are being surveyed. Even so, researchers in ethics have little choice in relying on self-reported attitudes and behaviors (Fernandes & Randall, 1992).

Finally, the data set is not overly large, which leads to the inability to generalize results for technology-based entrepreneurs and their firms.

## **RESULTS**

The average education of the respondents included some graduate school; a result that is similar to that of other researchers in technology based firms (Teach et al., 1985). The entrepreneurs were predominately male (69 males and 10 females). The respondents were CEO's, VP/COOs or others ranging from senior managers and engineers.

Three questions were answered differently by gender with differences that were significant at <.100 level. The firm position of the female respondents was not at the same level as the males;

more males than females were CEOs or VPs/COOs. More males than females had advanced education. All other responses were not significantly different, but because there were differences all female responses were left out of the ensuing analyses, resulting in sixty-seven firms with the two outliers noted earlier removed. Four firms that were either retail or distribution were all also removed resulting in sixty-three total firms.

Not all respondents answered all questions, making multivariate analyses such as clustering, factoring or discriminant analyses impossible. Thus only means testing was used. While strategies are multivariate in nature, the results nevertheless provided some insight into how these firms perform ethically. As firms covaried in size and age, no analyses were performed across the groupings, only within the groups.

*Hypothesis 1:* There is no difference in the ethical behavior of entrepreneurs due to the age of the enterprise.

Table 2 displays the results for this hypothesis. Responses were analyzed across the two age groups, firms five years of age or less or greater. On the question “my personal ethics are sacrificed to the goals of the business,” respondents in both younger and older firm strongly disagreed with this statement. It is interesting to note that in the Bucar and Hisrich (2001) study 52 percent of the entrepreneur respondents felt that personal ethics were sacrificed to goals of business. On the questions “when working with other firms we have been dealt with fairly” and “trying to respond to a variety of stakeholders produces conflict;” both respondents in both younger and older firms had very similar responses, agreeing to the truth of these statements. On

the last question posed, “I have conflicts when it comes to personal versus business decisions;” again respondents in both young and more established firms were similar in their disagreement.

The null hypothesis is thus supported by the results of the means testing. No significant differences at less than the 0.100 level between younger and older firms were observed.

---

Insert Table 2 here

---

*Hypothesis 2:* There is no difference in the ethical behavior of entrepreneurs due to the size of the firm.

Table 2 displays the results for this hypothesis. On the questions asked regarding business attitudes about ethical behavior, the responses for small and large firms did not significantly differ. Respondents in both small and large firms showed disagreement on the questions “my personal ethics are sacrificed to the goals of the business;” and “I have conflicts when it comes to personal versus business decisions.” On the questions “when working with other firms we have been dealt with fairly” and “trying to respond to a variety of stakeholders produces conflicts;” respondents in both small and large firms agreed.

The null hypothesis is supported by the results of the means testing. No significant differences at less than the 0.100 level between smaller and larger firms were observed.

*Hypothesis 3:* Entrepreneurs do not view themselves as ethical.

Table 3 displays the results for this hypothesis. Respondents in both younger and older firms agreed that “people are basically good” and “act honestly” but the smaller versus larger firms differences were significant and respondents in the older firms thought that people were “more” basically good. Perhaps this is due to younger firms finding it slightly more difficult to deal with others due to their lesser experience or perhaps they were more cynical due to their age. The younger, smaller and larger firms slightly agreed that "some people are hard to work with because of ethics." The older firms slightly disagreed with the statement. It may be that due to more experience these firms felt they were better able to work with ethical issues. All agreed that “illegal acts are unethical.”

---

Insert Table 3 here

---

*Hypothesis 4:* There is no relationship between entrepreneurial firms with positive ethical climates and established codes of ethics.

The results for hypothesis 4 are displayed in Table 4. For younger and older firms and small and large firms, whether the code of ethics is written or unwritten all respondents strongly agreed that the code of ethics is used in decision-making. The majority of firms have an unwritten code of ethics. The majority of smaller firms do not have a written code of ethics. Larger firms are fairly evenly divided between written and unwritten codes of ethics. Whether the code is written or unwritten, it is communicated to employees in a variety of ways. The means of communication written or unwritten include verbal and by example and combinations of both. The majority of smaller firms identified the primary means of communication of the code of ethics “by example.”

For the question “trying to respond to a variety of stakeholders produces conflicts” young and old firms, small and large, with written and unwritten codes agreed. Significantly different, but both agreeing, younger firms responded more positively. Large and small firms with an unwritten code of ethics also agreed that “trying to respond to a variety of stakeholders produces conflicts.” On the question “I have conflicts when it comes to personal versus business decisions,” younger and older firms, smaller and larger, with unwritten and written ethics codes relatively strongly disagreed with the statement.

The hypothesis is not supported.

Insert Table 4 here

---

## **Other Research**

In Table 5 the results of the Bucar & Hisrich (2001) study were compared with the present study. On the question of “code of ethics used in decision-making” 73.5 percent of the Bucar & Hisrich entrepreneurs responded yes when asked if a code of ethics was being used. In the present study entrepreneurs also very highly agreed that a code was used in decision-making. On the question of personal ethics sacrificed to goals of business 52.5 percent in the Bucar & Hisrich study agreed with the statement. In the present study entrepreneurs very strongly disagreed. This difference may be due to the types of firms used in both studies and perhaps because of changes in the ethical environment brought on by the Enrons of the world. On the question “personally dealt with fairly by business” Bucar & Hisrich entrepreneurs agreed by 93.3 percent. In the present study entrepreneurs agreed but not as strongly.

On the question of “man is basically good” Bucar & Hisrich’s study had a strong positive response of 88.8 percent. The present study responses were in agreement, but again not as strongly as the Bucar and Hisrich response. “Others reciprocate honestly” was a question with which Bucar and Hisrich had a 67.7 percent positive response. The present study responses were also in agreement with the statement. In both studies entrepreneurs agreed with the statement “Things illegal are ethically wrong”. In both studies, there was strong agreement that a code of ethics was used in decision-making.

Insert Table 5 here

## SUMMARY/CONCLUSIONS

The findings provide support for the use of a code of ethics in decision making by entrepreneurs in incubator technology firms, whether a code of ethics is unwritten or written, irrespective of the age or size of the firm. The findings also support that in these firms there is agreement that illegal acts are ethically wrong. This study found that entrepreneurs did not find that their personal ethics were sacrificed to the goals of the business. Entrepreneurs in technology incubator firms defined people as basically good and honest. These results support Newbert's (2003) positive view of today's entrepreneur, i.e., not solely interested in material wealth. There was no difference in ethical behavior due to the age or size of the firms. Respondents do view themselves as being ethical. These responses indicate that entrepreneurs see themselves as ethical and believe that their firms are being operated ethically.

A comparison of this study with a prior one (Bucar & Hisrich, 2001), utilizing similar questions, indicated some differences in responses. These differences likely were due to both differences in sample sets as well as the time frame of the study, with the examples of Enron and other unethical firms likely impacting the more current responses. As always, generalized results do not allow for specificity by firm types, but the current study does provide empirical data for incubating technology based firms, although male only responses.

Additional research is needed to identify the factors that influence ethical decision-making in entrepreneurs, both male and female, and their firms.

The findings with regard to the ethical climate and codes of ethics in entrepreneurial firms provide significant and interesting implications for both practice and research. The majority of

entrepreneurial firms do not have codes of ethics that are written. Many entrepreneurs responded that their ethics code was “unwritten” and communicated either verbally or by example. Due to the scrutiny that external stakeholders are applying to firms of all sizes, and especially due to the negative anecdotal and theoretical perspectives on entrepreneurs, the one recommendation that could be made as a result of this research is that entrepreneurs need written ethics codes. While generalizing, the results support much of the research in the field that shows entrepreneurs think of themselves as ethical and their firms as acting ethically. The difficulty is in ensuring that the reality fits the image and the image fits reality.

### **ABSTRACT**

In the Middle East countries and specially the AGCC countries (Arab Gulf Cooperation Council consisting of Oman, Saudi Arabia, UAE, Qatar, Bahrain and Kuwait), the process of participation of the women in enterprise and businesses has been given due attention in the recent past. The long term development strategy, "Vision 2020" adopted by Oman has provided an encouraging environment for women entrepreneurs to participate and contribute towards this effect. Availability of education, training and awareness has helped Omani women to emancipate in recent past and resultantly, Oman has a significant number of women entrepreneurs in the male dominated Arab society.

In Oman, two main programs namely "**Fund for Development of Youth Projects**" and the "**SANAD**" Program have been launched in recent years to promote entrepreneurship for both men and women. The Youth Fund was established in 1999 and it encourages young Omani men and women to start small and medium enterprises. This program has been successful to some extent in attracting young entrepreneurs. The SANAD program was started in the year 2001, its main objective is to speed up the process of Omanization by creating self employment

opportunity. This program has attracted a significant number of women who are interested in establishing their micro-enterprise.

Training and development plays important role in making women entrepreneurs successful. “**Intilaaqah**” program was established in 1995 by Shell Oil Co. in Oman to provide training, counseling and consultancy and its role in supporting women entrepreneurs has been very encouraging with its limited resource.

Key Words: Women Entrepreneurship, Oman.

## **INTRODUCTION**

Since 1980s, policy makers worldwide have been considering the role of women entrepreneurs in the process of economic development. The participation of women in the global economy has been tremendous in the recent past. Worldwide, it is estimated that approximately one third of all businesses are owned by women (Lerner and Almor, 2002; OECD, 2000). The number of women of women-owned businesses and enterprises are also on the increase in Asia, Africa, Eastern Europe and Latin America. This strong presence of women entrepreneurs is noticeable since many studies have shown that business creation and development is an even greater challenge for women than men. Access to credit, reconciliation of work and family, cultural barriers, among others, have been pointed out as obstacles that women business owners have to overcome in order to succeed in their venture (OECD, 2000). The other problems faced by the women entrepreneurs are marketing/sales skills, management skills, access to markets, awareness of business support, discrimination by finance providers, discrimination by support providers, and overall discrimination in the economy and society which are visible or invisible at times.

## **WOMEN ENTREPRENEURS: EMERGING CHALLENGES**

The lack of role models in entrepreneurship is one of the many obstacles for women entrepreneurs. There exists a strong connection between the presence of role models and the emergence of entrepreneurs (Shapero and Sokol, 1982). Women historically have not been present as entrepreneurs in general and consequently have lacked close role models. The influence of role models is gender related. That is, an individual will be more influenced by another individual of the same sex, as one’s aspirations and choices tend to be more influenced by persons of the same sex (Deaux and Lafrance, 1998). This is a result that has been replicated in different countries and employing different methods. The presence of role model helps women to develop attributes making them a keen follower and achiever.

Lack of awareness and experience among women is another obstacle. All stages in entrepreneurship development are dependent on relevant experience, from the identification of opportunities to the execution of running a business. The access to information is vital in this

information age and only those people will survive in this highly competitive world who are informed and groomed to handle information to make appropriate decisions. This truly applies uniformly to the big MNCs (Multi-National Corporations) or the small and medium size business. The women entrepreneurs lack the proper awareness and relevant skills and experience to handle the business environment that is uncertain and guides entrepreneurs to thrive on chaos.

Recent research on developed economies has identified a potential problem when it comes to women's entrepreneurship: highly educated women seem to choose other career options than self-employment and entrepreneurship (OECD, 2004). Entrepreneurship is therefore relatively more dominated by unskilled women or very skilled and already wealthy women. Skilled women must therefore become more attracted to entrepreneurship. If women are relatively less skilled than their male counterparts, *ceteris paribus*, then the firms they will create will have a lower probability of survival and growth than the firms created by men.

Lack of relevant networks and of societal position for women is another impediment. Women have in general a lower social position than men, which affects the kind of networks they can access or participate. There is evidence to prove that women are less involved in networks than men are, and their type of network is different. For business, it is as important to have weak-tie networks as strong ties (Aldrich and Zimmer, 1986; Burt, 2000; Granovetter, 1985; Granovetter, 1973). The strong and personal networks that women traditionally engage in are well suited to purposes linked to the family related tasks that may prove to be a hindrance in the marketplace (Lin, 1999). Thus, women differ from men in the kind of networks they use and in the social capital available to them through the network. Women have therefore less access to critical resources, support and information needed to successfully start and manage a new firm compared to men.

Lack of wealth among women is a hindrance. A prerequisite for starting a firm is to have capital in terms of financial assets and in terms of relevant knowledge assets. Women's positions in society have led to a lack of assets in both these aspects. The constraints of family obligations make it harder for women to take on work on a full time basis and to engage in a career. This in turn decreases the range of possible work opportunities for women, leading to jobs in lower paid sectors. Being a part-time worker with low pay will not permit creating personal wealth.

Some major areas have been identified as potential or real problems for women when it comes to financing: a) women may be disadvantaged in raising the initial capital to start a new firm; b) collateral needed for external financing may be above the wealth level of most women; c) financing for an existing firm may be less available, because women are less likely than men to penetrate informal financial networks; and d) women entrepreneurs' relationship with different financial institutions might suffer because of gender stereotyping and discrimination (Carter *et al.*, 2001; Storey, 1994).

Another recurring obstacle for women to engage in entrepreneurship is the perceived lack of time or competing demands on time. Because women are responsible for so many different domestic chores and the raising of children, they do not have enough free time to develop either their entrepreneurial skills to become entrepreneurs or to develop an existing business. The lack of free time does not allow them time to travel to institutions, banks and other finance houses for advice and information on credit, to attend training programs to acquire skills, or to seek out

better customers or suppliers. This lack of free time has been observed in a number of studies across different countries: for example Bangladesh (Karim, 2000), Côte d'Ivoire, Ethiopia, Mali, Morocco, Senegal and Zimbabwe (De Groot, 2001), or Sweden (Holmquist *et al.*, 2002). The results suggest that lack of time is a barrier for most women, in most economies, independent of the level of development.

Low female participation has also been blamed on social norms. For example, this is seen in the drop in female labor force participation that occurs with marriage. In Egypt, female market work drops sharply with marriage rather than with childbearing (Assaad and El-Hamidi, 2002). In Iran, married women have the lowest participation rates, followed by single and widowed women. Divorced women participate at a rate three times that of married women with similar characteristics (Salehi-Isfahani, 2000). In Kuwait, labor force participation of single women aged 25-39 is more than twice that of married women at 60 percent compared to 30 percent (Shah and Al-Qudsi, 1990). Gender norms have proven resistant to economic change and costly for growth.

In the Middle East countries and specially the AGCC countries (Arab Gulf Cooperation Council consisting of Oman, Saudi Arabia, UAE, Qatar, Bahrain and Kuwait), the process of participation of the women in enterprise and businesses has been a concern. With this literature review, this paper evaluates and analyzes the existing entrepreneurship policies of the Sultanate of Oman for promoting women entrepreneurship and identifies the problems and bottlenecks associated with its implementation.

## **EMANCIPATION OF WOMEN IN OMAN**

Participation of women in the economy is the real barometer of women empowerment in any society. Education and training of women play a key role for women development and empowerment. In a country like, Oman, until 1970, the women education was non-existent. The country had only 3 primary schools with 900 boys and there was no provision for education of girls. Following the accession of His Majesty Sultan Qaboos in 1970, education was made available to all Omani nationals alike irrespective of sex. The opening of the co-educational Sultan Qaboos University in 1986 and making the primary to tertiary education available to women played a key role towards the efforts of emancipation of women in Oman (Al-Lamki, 1999; Oman Daily Observer, April 1996). Since 1970, Oman has achieved a lot in making education available to boys and girls alike. From 3 schools and 900 students in 1970, it has reached 1,020 government schools and 134 private schools with 601,461 students studying in schools of which girls constitute nearly half (Ministry of Information, 2002: 119).

The girls have been at the top of the students merit lists in the secondary schools for more than a decade and this domination is spreading to the degree courses of the Sultan Qaboos University as well. The girls are performing very well. The declared government policy guarantees women equal rights in both education and employment as enshrined in the Personal Status Law (PSL). His Majesty has repeatedly called upon female citizens to lend their full support to the development of the country. He has frequently described them as representing "half of Oman's potential". Oman is rightly proud to be first Arab country to appoint a woman as its overseas ambassador and currently, three women hold positions of council of ministers with a fourth having an equivalent role. Today, women are playing important role in the Consultation Council (Majlis A'Shura) and the State Council (Majlis A' Dawla) and recently, five women were

appointed as attorney generals to the legislature. In October 2004, a woman was appointed as the minister of social development. Though there is no official data available, it is likely that Oman employs the largest number of women in AGCC countries. (Ministry of Information, 2003, see also [www.omanet.om](http://www.omanet.om)).

The General Directorate for Women and Children Affairs was established in 1985. The directorate under the auspices of the Ministry of Social Affairs and Labour has set up a network of women development centres throughout the country. The general aims and mission of the Directorate is to setup special programs to deal with mother and childcare, eradication of illiteracy, education, the development of traditional and modern handicraft and many other programs related with developing the women minds and strengthening their role as responsible citizens. This was a significant move by the government to enhance the status and role of the women in Omani society (AlLamki, 1999).

The Omani Women's Association (OWA) was established in 1970 as a voluntary organization and has played a significant role in the development of women in the Sultanate. It is envisaged that the OWA could be instrumental in providing a network for Omani women who are employed (AlLamki, 1999) or running their own businesses. It is the first women's organization in Oman that was formed with the main aim of providing quality education and training to women in increasing their knowledge so as to facilitate them to secure good jobs. OWA also promotes the traditional Omani custom and values so that the tradition culture continues to remain in the country. It encourages its members to actively contribute to the economy by whatever ways possible. At the end of the year 2003, there were 39 local OWA groups established all over Oman that had 2,738 members (Ministry of Information, 2003). A Women's Voluntary Work Co-ordination Committee has been created to regulate the activities of the OWAs and help Omani women to play active role in the economic and social development programmes. There are four government centres as well as six non-government training centres for women being run which help raise women's general awareness about cultural, health and social issues, develop their productive skills and enable them to make profitable use of their leisure time (Ministry of Information, 2003). The role of OWA has been very encouraging in helping women to learn skills and education and make them self-reliant. It has been helpful in harnessing the traditional craftsmanship of women and building confidence and competency to deal with the hardships of life and occupation.

Thus Oman women have come a long way in the last 10-15 years. In 1993, Women constituted 9 percent of the total Omani labor force and three-fourth of them were employed in government sector (AlLamki, 1999). Today, women participation in private and public sectors has increased significantly. In the last ten or more years there have been tremendous increases in women participation in employment. Women comprise 36 percent of employees in the Omani public sector as of now and most importantly, they are participating actively in decision-making and occupy leading posts in government sector (Oman Daily Observer, January 9, 2005). Thus, the participation of women in education, employment and decision-making has grown considerably and it has resulted into the emancipation of Omani women in the twenty first century presenting an example for other Arab countries to follow.

## **OMAN ECONOMY AND THE ENTREPRENEURSHIP ENVIRONMENT FOR SMALL BUSINESSES**

Oman is the third largest country of the AGCC countries bordering Yemen, Saudi Arabia and the United Arab Emirates lying on the southeast corner of the Arabian Peninsula. The commercial export of oil began in 1967 in Oman. Since then, oil has been the major contributor to the GDP. The fourth five-year plan (1991-1995) for the first time emphasized the need to diversify the production base other than oil and the Government paid special attention to the sectoral and regional development process.

The Government of Oman identified the role of privatization and liberalization of its policies to accelerate the rate of economic growth. Government encouraged men and women equally to participate in the process of economic development of the Sultanate. The fifth five year plan (1996-2000) considered as did the first plan within the framework of the long term development strategy (1996-2020) also emphasized on the diversification of the national income resources encouraging the domestic and foreign private investments and increasing the share of the private sector in the total investments. It also emphasized the role of human resources and participation of Omani men and women in the private sector development and diversification process (Ministry of National Economy, 2002)

By 1995, Oman had completed four five-year plans. Taking advantage of its earlier planning and visualizing the changes in the global economy, a new vision of Oman's economic future evolved. "Vision Oman 2020" proposed a policy for the Sultanate's development over twenty-five years (1996 to 2020). It took into account the far-reaching changes in the world economy and the revolution in telecommunications and information technology that has transformed the global system of production and exchange. In fact, "Vision Oman 2020" represents a dividing line between two stages of the Sultanate's economic and social development, marking both the end of initial development up to the country's Silver Jubilee celebrations in 1995 of the accession of His Majesty Sultan Qaboos, and a new journey into the third millennium. The vision stipulated that the contribution of crude oil to GDP is expected to drop to around 9 percent in 2020, compared to 41 percent in 1996. Gas is expected to generate 10 percent of GDP in 2020, compared to less than 1 percent in 1996. The industrial sector is expected to increase its contribution from 7.5 percent in 1996 to 29 percent in 2020 (Ministry of Information, 2003).

Subsequently, the sixth five year plan (2001-2005) emphasized three core goals for this period: a) the development of human resources and basic structures, b) economic diversification, and c) encouraging growth of the private sector.

The key aims of the Sixth Five-year Plan were to:

- guarantee stable personal incomes;
- increase the number of secondary school students enrolling in higher education and technical colleges;
- create more jobs for Omanis;
- adopt sustainable financial policies;
- promote economic diversification ; and

- develop the private sector.

The sixth five-year plan envisioned growing the national economy by an annual average rate of 4 percent and increasing the per capita GDP share at constant prices at average annual rate of about 1.9 percent (Ministry of National Economy, 2002: 67). In fact, the result has been encouraging and the Omani economy grew to a higher level than what was envisioned in the Plan for the year 2001 due to the increased value of the non-oil sectors and higher than the predicted oil prices (Ministry of Information, 2003).

Oman joined the WTO in November 2000 which has provided significant challenge for the country to liberalize its policy without compromising its objective of Omanisation in ownership and employment. It is expected that with joining WTO, the efficiency of certain sectors, especially finance and telecommunication and also the tourism and manufacturing sector, will increase and Oman manufactured products will penetrate into the markets of both developed and developing countries, especially, the exports of petrochemical (Kamoonpuri, 2004:13).

### **Development of Small and Medium Enterprises**

The sixth five-year plan place emphasis on the industrial development of small and medium enterprises (SMEs). The plan also puts emphasis on creating employment opportunities through economically feasible labor intensive production facilities. Though there is no separate policy framework drawn up for the SMEs, the government has adopted certain steps in this regard like the availability of Oman Development Bank loans, incubator facilities, equity funding by the Youth Fund, and micro-business development facilities offered through the SANAD program. The small entrepreneur development facilities offered by Intilaaqah represent contributions by the private sector. These programs aim at promoting the small and medium enterprises in Oman (Kamoonpuri, 2004:13). Michael Porter who has written extensively on competitive advantage is of the view that “Oman could become a role model for the region if the country focuses on certain priorities”. He identifies five important priorities in this direction and is of the view that launching a comprehensive program for entrepreneurship and developing strategy to attract investment and developing a cluster strategy is very important (Times of Oman, Dec. 2, 2004).

### **Creation of Oman Development Bank (ODB)**

The ODB has encouraged young entrepreneurs in establishing their small businesses in the recent past. In fact, ODB plays pivotal role by promoting entrepreneurship among the youth by providing them soft loans (a loan with generous repayment terms) and curtailing bureaucracy. ODB was established as a public joint-stock company in April 1997 by a royal decree with a capital of RO 20 million after a merger took place between the Oman Development Bank and the Oman Agriculture and Fisheries Bank. The main functions of ODB are: to support small and limited cost projects; to encourage would-be and upcoming entrepreneurs; and to finance private sector projects in several fields, including industry, agriculture, fisheries, animal resources, exports, tourism and self-employed and workshop projects, through the making of medium- and long-term loans and capital participation. It also offers technical assistance and consultancy services. ODB is also responsible for the making and recovery of government-backed soft loans, export credit guarantees and distribution of proceeds from the Fisheries Research Fund. By the

end of 2002, the ODB had advanced loans totaling Rial Omani (RO) 45.1 (around USD 115) million with government subsidized annual interest rates of between 2 percent and 6 percent. The ODB's assets stood at RO 64.1 (around USD 166) million at the end of 2002 and its paid-up capital totaled RO 20 (around USD 51) million. ODB enjoys exemption from all taxes, and the government subsidizes the interest rate on the soft loans. (Ministry of Information, 2003)

## **WOMEN ENTREPRENEURSHIP IN OMAN**

There is no separate program or policy to develop women entrepreneurship that exists in Oman but women participation in the small businesses has been encouraging lately. More and more women have come out and ventured into business in the recent past. In Oman, two main programs namely **“Fund for Development of Youth Projects”** and the **“SANAD”** Program have been launched to promote entrepreneurship for both men and women.

### **Fund for Development of Youth Projects**

The Fund for Development of Youth was established in 1999 and it encourages young Omani men and women to start small and medium enterprises. The fund provides financial and management assistance to young people wishing to embark on business in the private sector. In its first year of operation, 15 projects were financed. The fund was established with a grant of RO (Rial Omani) 1 million granted by His Majesty and the fund has accumulated RO 5.36 million as equity from the private companies. The fund's financial involvement is limited to half the capital of each project and the maximum available is RO 50,000 (1 RO= 2.6 US \$). The fund ascertains the economic viability of the project and provides consultants from banks and corporations who give technical and administrative advice voluntarily to get the project started. The beneficiaries are exempted from the company income tax for a period of 10 years that may be extended for a similar period. It also provides exemption from the corporate tax and tax on profits for five years to the fund's industrial and commercial projects. The main emphasis in this project is the viability of the project and the promoter must be an Omani. Since its inception in 1999, 20 projects had been funded by September 2003. The youth fund concentrates more on quality rather than quantity (OER, 2003:26).

The policy by this fund is to invest in the equity of the small and medium sized projects and to render administrative, financial and technical support. The entrepreneur has the flexibility to buy back the equity in his or her enterprise by paying back to the fund after an exit period of 5 years. The idea of the fund was very innovative but it has not been so successful in attracting young entrepreneurs. The entrepreneur feels that their freedom of decision-making and enterprise is limited by the involvement of the fund in the administration of the business.

As far as, the women participation in this fund is considered, it has not been able to attract the numbers of women entrepreneurs as large as the SANAD program. The objective of this fund is also different as it focuses more on a bigger enterprise in comparison to the SANAD program. There is likelihood that the provisions of this program will be revised to attract more entrepreneurs in time. It should also attract women entrepreneurs as a category making special provisions to cut down the bureaucracy. Even the equity idea can be intertwined with the normal funding proposition as adopted by other financial agencies.

## **SANAD Program and Women Entrepreneurship**

SANAD is targeted for the unemployed youths. “SANAD” means support in Arabic that succinctly describes the primary objective of the SANAD as Self-employment And National Autonomous Development (OER, 2003: 23). This program helps in creating business opportunities for Omani men and women. The SANAD program was started in October 2001 under the Ministry of Manpower with an objective to help promote and foster the development of small-scale enterprises in Oman. It encourages and sponsors the individual initiatives and the self-employment projects. The program provides opportunity for men and women job seekers, craftsmen/craftswomen and vocational aspirants to start and run their own business. The age group chosen for this program is 18-40 years and under this program a loan of 5,000 Rial Omani (around \$13,000) is provided as a loan. The period of loan settlement is seven years including one year as a grace period. The Government has created SANAD offices in each governorates and regions that provide technical and administrative support to the beneficiaries.

### **General Objectives of the SANAD Program**

- Supporting the work-seekers (vocational and craftsmen) by establishing individual and family self employment projects and by sharing in finding job opportunities for workers of different educational and vocational levels with those who are interested in investment as business owners.
- Participating in spreading the individual initiatives and enhancing the efforts of self-independence as a condition to achieve the everlasting development.
- Supporting the developmental efforts by establishing productive and serviceable small projects as a main source of the national income.
- Enlarging the base of private sector and businessmen.
- Developing the small projects sector and suggesting the policies and mechanisms for realizing them.
- Participating effectively in the Omanisation plan in the private sector.
- Mobilizing the efforts for deepening the idea of free business and enhancing the initiatives for work and production in the minds of youth and Omani society.

For this program, the targeted categories chosen were the jobseekers (male and female) including the new graduates who were interested in starting small projects managed by them and, craftsmen who were interested in starting new productive or serviceable work for themselves or interested in expanding their existing business. Twenty two sectors were selected as focus areas namely: grocery shops (sale of food stuffs); vegetables and fruit shops; sale and supply of electrical items; sale of watches; masterpieces and gifts; sale of ready-made garments; sale of natural flowers; delivery vehicles; carwash; Internet café; photography shops; sale of fish; butchery shops; poultry shops; home appliances maintenance; sale and repair of tires; electrical

installation; sale and supply of electrical items; repair and maintenance of home cooling appliances; painting of buildings; house furniture upholstery; carpentry shops; iron smithery shop (metal doors and windows); and goldsmithery shops.

In addition to these occupations and businesses, the applicant is free to choose any business of his or her choice. Some of the basic conditions that are stipulated for the approval of the projects are as follows:

- The project should provide a new job opportunity.
- The project should have suitable technical and economical benefits.
- Local raw materials to be used in the project.
- Products of the project should be of good quality and easy to market.
- Modern technology to be used in the project.
- The ability to continue and expand in the future.
- The project should comply with the conditions and requirements of the environment preservation.
- The project should satisfy the need for quality products at competitive prices.
- It should employ 100 percent Omani workforce.

Some other conditions of this project are that the applicant should be able to read and write well, not employed at present, and be fully free for the project. For the loans for sewing and designing clothes, which are the women's domain, a training certificate has to be enclosed. The applicant must have a personal guarantor (father, brother, sister etc.) and have a place for establishing the project (owned or rented). One is also required to present a feasibility study of the project showing the cash flow during the period of the loan and an acknowledgement to employ Omani manpower only (Ministry of Manpower, 2004).

The Oman Development Bank disburses the loan amount after approval and recovers it as per the Fund regulations. The period of the loan settlement is seven years including one year as a grace period starting from the date of granting the loan. The fund charges an interest rate of 2 percent per annum to cover the administrative cost of the loan. The SANAD offices in the governorates and regions provide the technical and administrative support to the beneficiaries by providing advice and consultancy services to the owners of the small projects regarding the activities to be practiced, organizing short courses for training the owners regarding management, accounts, cost and marketing with the cooperation of the concerned parties in the public and private sectors, and follow-up of the projects in order to be assured of quality whether they are goods or services. It also solves the problems and difficulties that may be faced by these projects. It also helps in marketing the products and suggesting the possibilities available inside or outside the Sultanate. More importantly, it also conducts periodical evaluation of the small projects and their effects on the targeted categories of businesses (Ministry of Manpower, 2004).

### **SANAD and Women Entrepreneurs**

The SANAD program has been successful in helping young entrepreneurs and so far it has benefited 8581 entrepreneurs (during 2002-2004). Out of which 37 percent<sup>1</sup> funds have been provided to women. In total, it has created job opportunities for 10,000 Omanis in different

activities like foodstuff outlets, SANAD committee projects, vegetables and fruit outlets, management of school canteens and others (See Table 1). The program has trained 1,921 people who started their own businesses. At present, it is running four incubators, out of which three are targeted for women entrepreneurs for whom training is being imparted in tailoring and fashion designing. There have been 1,117 people trained and almost all of them are women<sup>1</sup> (See Table 2).

---

Table 1 here

---

---

Table 2 here

---

As of the end of 2004, the success rate of this program is 76 percent. The beneficiaries are repaying their loans and running their enterprises successfully. Though there is no separate data available on women entrepreneurs' success rate, it is thought that the success rate is higher in case of women entrepreneurs. This trend is not specific to any particular district rather in all wilayas (districts). Women have emerged as more responsible and serious entrepreneurs. They are diligent and hardworking and they do what is required to make a business successful<sup>2</sup>.

The Omanisation process has been intensified through the SANAD initiative in certain activities and establishment and the foodstuff outlets has been Omanized in 45 wilayas out of a total 59 wilayas of Sultanate. It is planned to achieve 100 percent Omanization in foodstuff outlets by May 2006. The participation of women in this drive is quite encouraging and the total participation of 37 percent of women with high success rate is reflective of the bright future of women micro-entrepreneurs. The recent impetus to the training of women through the SANAD program will surely increase their participation tremendously in coming years.

### **Intilaaqah Program and Women Entrepreneurs**

**“Intilaaqah”** program was started by the Shell Oil Company in Oman in the year 1995. It is part of the Shell group worldwide initiative, LiveWIRE. The Intilaaqah in Arabic means “rapid take-off”. This program helps the young entrepreneurs by providing them the right kind of training, counseling and consultancy services which enables them to start their own businesses. The objective of the training program imparted by the Intilaaqah is to develop the candidate's ability to conceptualize the business environment by enabling him or her to acquire necessary skills to run small businesses professionally. This program targets young men and women who are 18-35 years of age and are unemployed or self-employed. They should have a viable business idea and have approval from a funding institute or have the financial ability to start their businesses ([www.intilaaqah.org](http://www.intilaaqah.org)).

A number of companies sponsor (See the Table 3) the trainees who get a National Vocational Qualification (NVQ) level 2-3 in Business Planning and Ownership to start a micro project or a

small and medium enterprise (SME). The training program duration is three months and the training is imparted in Arabic and covers all aspects of setting up and running a business. It covers issues like market research, preparing cash flow, and financial forecasts, importance of the right location, use of computer and proper filing system. This program also provides counseling support and advice to the beneficiaries. It has a network of voluntary advisers besides after care support to its graduates who have started their enterprises. The program conducts workshop for the young entrepreneurs and it also give awards to the best businesses every year to boost the motivation of the entrepreneurs (OER, 2003: 25).

The initiative taken by Intilaaqah is helping the diversification strategy adopted by the government to move from oil sector to non-oil sector by creating gainful employment and contributing to the GDP. The program which was initiated in Muscat area has been expanded to 18 centers across the Sultanate (OER, 2003: 25). It has trained 680 people so far (upto the end of 2004, since its inception in 1997) out of which 49.2 percent are females. The women participation in training has been more accentuated in last four years. In fact, the women constitute more than men i.e., 53.25 percent in the training imparted to the young entrepreneurs by Intilaaqah in last four years during the period 2001-2004 (See Table 4). The kinds of business which women have started after the Intilaaqah training are: tailoring of ladies dresses; photo and video shooting in wedding parties; sale of readymade garments; beauty saloons; and health clubs.

The success rate of Intilaaqah program is high and only 32.05 percent of trainees who have gone through the three-month training program are unemployed. The percentage of trainees who have joined organizations for gainful employment is 34.26 percent. This shows that the participants get attracted towards good jobs rather than running their own businesses. However, 26.76 percent of trainees are able to start their business and they have created job opportunities for 383 people (See Table 5). Though, the gender-specific data was not available; it was suggested that was an equal percentage of the success rate<sup>3</sup>. As women participation has already been more than half of the total participation in the last 4 years, the role of young Omani women is going to be more important in the near future.

---

Table 3 here

---

---

Table 4 here

---

---

Table 5 here

---

Intilaaqah also gives award to young entrepreneurs for successful running of their businesses. It gives awards in five different categories: the best entrepreneur, the best business in terms of Omanization, the best business idea, best display and best Intilaaqah progressed startup for the

Intilaaqah trainees. In 2004, 13 entries were short-listed for the award and out of which four were women. The 2004 award for the best entrepreneur and the best display award were won by women. The best entrepreneur award was also won by females in the year 2000 and 2002<sup>4</sup>.

### **Role of other Agencies in Promoting Women Entrepreneurship in Oman**

The role of voluntary private organizations is very important in establishing the network of the entrepreneurship programs. The sensitization of the society to the concern of Omanization in terms of employment and ownership is important in this regard and all stakeholders have to play their active role in encouraging and promoting small and medium enterprises to move its reliance from oil sector to non-oil sector. The role of the Omani Women's Association (OWA) has been important in this regard. OWA is attracting more and more women to become its members so that it can help and support women by making them more self reliant and productive. Awareness is the first and foremost affair for women entrepreneurs and it can play a more important role in this regard. OWA organizes seminars and other activities concerning women. It also participates in various seminars and workshops organized by many international women's forums and organizations. The members can participate in such seminars and take an active part in them. They can also take part in the local seminars organized by other organizations concerned for their interests. OWA has plans to expand its activities by inducting more experts who would provide training in the fields like IT and administration. OWA is also helping the young women realize their dreams and it offers courses free of cost to its members in areas like computing, tailoring, and interior designing. Members can project their skills and also sell their products at exhibitions held by OWA or by participating in exhibitions and trade fairs organized by other organizations (Aman Daily News, 2002). These efforts will surely help women in becoming more empowered and visible in the Omani society. The local community development centres (LCDCs) funded by the Ministry of Social Development also help women to improve the quality of life for their families and improve their contributions to the community. The role of both OWA chapters and LCDCs becomes very important in promoting entrepreneurship in women.

In 2004, a new voluntary organization of businesswomen, "Women in Focus" was launched in Oman. The primary goal of this forum is to establish a platform for the Omani women through which they can contribute vigorously to the community. This forum will underline the role of women as partners and leaders in the business and professional sectors. The four areas of concern identified by the forum are: networking; mentoring; training; and research. This forum will encourage networking among women that will help in sharing their learning and experiences. Women who are relatively new to the workplace and who manages the enterprises will have an opportunity to learn from each and other. The role of women as role model and mentor is also important and helps any society in encouraging the women participation in vocations and enterprise (Khaleej Times, 2004).

### **Women Entrepreneurs as Role Model in Oman**

Oman has been known for its trade and businesses for ages. The great Sindbad story and the role of Oman as a prosperous seafaring nation is well known. There have always been a great number of role models in the Omani society. As of today there are also entrepreneurs who are role models for others. One such example is the founder of the Bahwan group, Sheikh Saud who

started his small non-descript shop in Muttrah souq selling Toshiba TVs and Seiko watches and went on to establish one of the most successful business houses in the Gulf region touching an annual turnover of US \$ 1 billion (Kamoonpuri, 2004: 10, 18). There are plenty of such male examples available for the young entrepreneurs in Oman. But women need role models who are women which they can imitate and relate to them. The tradition and cultural background of the society makes it more important to find out the role model who can play important role in encouraging young entrepreneurs.

Recently, the participation of women in all spheres has made such role models available in Oman. Women are visible everywhere. In a documentation of successful entrepreneurs in Oman undertaken by the government-sponsored press (a national daily, Oman Daily Observer), 23 such entrepreneurs were identified with 5 being women. This indicates the achievement of women entrepreneurs in recent time. One such figure in recent time in Oman is Lujaina Mohsin Haider Darwish. She is a woman of multi-faceted personality. She is an academician, entrepreneur, and politician all embedded in one. She was chosen as “Young Entrepreneur of the Year 2001”, an award given by ‘Oman Awards for Excellence’ instituted by the private sector to celebrate the accomplishment of individuals. Lujaina is member of Majlis A’Shura for the second term. She is also an active member of the board of Oman Chamber of Commerce & Industry (OCCI). She is trying to form a committee that will provide women entrepreneurs a platform to create business contacts and additional leadership skills. She feels that the proposed committee will help in building partnership between local communities, society and government to provide access to finance, business mentoring and other kind of support to young women entrepreneurs. She is of the view that the government of Oman is determined to promote policies and programs which remove barriers to growth and ensure the long term viability of women in business (Kamoonpuri, 2004: 95-100).

Sabrah Al-Riyami is another role model. She represents the new breed of entrepreneurs of Oman. She began her career by joining Oman TV as one of the first GCC national woman television journalists. Later, she co-founded a company that provides services for event management, tourism, and filming. She was chosen as the “Young Entrepreneur of the Year 2002”. Her company Darran LLC was the first company in the Middle East to receive the Gold Star Award in 2002 and Diamond Star Award by the Business Initiative Direction, Spain. She feels that the Sultanate recognizes the contribution of women entrepreneurs in the national economy. She is of the view that women are more likely to be interpersonally aware than men. She suggest business women are often more people oriented and less authoritarian and use a participative or interactive management style in running their businesses resulting in forging a lasting relationship with employees and clients (Kamoonpuri, 2004: 143-148).

## **CONCLUSION**

The efforts undertaken by the Government has been fruitful in Oman and women have equipped themselves with appropriate education and motivation in recent times. Oman has a significant number of women entrepreneurs in the male dominated Arab society. The participation of women in SANAD program is 37 percent and this is likely to increase seeing the fresh impetus being given to women training and development. The women participation in public sector employment has also increased significantly from a mere 9 percent in 1993 to 36 percent in

2004. The participation of women in education and employment has been tremendous in recent past. Women constituted 54 percent of students entering the universities in Oman in 2002.

Diversification of the economy of Oman from dependence on oil and gas, non-renewable sources have led to a drive to encourage the employment of Omani nationals instead of relying on a high percentage of expatriates in the labor force. Women who form about half of the population have an important role to play in this regard (Khoury and Moghaadam, 1995: 35)

The most common problem related with the women businesses in Oman are that most of these are concentrated in service sector and run on small size. There is lack of network and forum in Oman where women can share their learning and exchange information, it makes them a disadvantageous group. (McElwee and AlRiyami, 2003: 345). Establishing network, and encouraging women to participate and share their learning and experience is also important. Though, the role of OWA and LCDCs has been important in handling more of the social issues in Oman, it is required that these efforts can be integrated with the economic empowerment of women. There is a need to create and organize more networking agencies which can provide a platform to women entrepreneurs and its approach should be pervasive involving all regions and all size of enterprise in Oman.

The existing programs like SANAD, Youth Fund and Intilaaqah needs to be reevaluated. The SANAD program that is being run under the Ministry of Manpower should be equipped with more resources and infrastructure to deal with the Herculean task given to it. It needs to provide more training by establishing incubators and training centres. The Youth Fund also needs appraisal to involve more and more women entrepreneurs and to widen its coverage. It can broaden its base by providing support and fund without holding equity and involving smaller enterprises. The size of the Intilaaqah program is also small seeing the number of job seekers in Oman and those interested in establishing their businesses. It needs to train more and more women entrepreneurs to widen its coverage. In fact, such training should be available to all those who wish to start their businesses. Sensitization of youth by media and providing awareness to them is a must for encouraging entrepreneurship for men and women. Including a chapter on the SANAD program in high school textbook and showing concern by the government is a welcome step in this regard. These steps will surely help women entrepreneurs to equip themselves with proper skill, competency, support and motivation to contribute to the process of diversification of the national economy and their social and economic empowerment.

## ENDNOTES

1. No segregated data is available for men and women. This data was provided by Mr. Salem AlNabhani, Executive Director, SANAD program in an interview conducted by one of the authors on March 6, 2005.
2. This view was expressed by the Executive Director, SANAD Program.
3. This information was provided by Mr. Al-Mutassim, Intilaaqah program.
4. Information provided by the Intilaaqah office, Muscat.

# **RURAL ENTREPRENEURSHIP IN KENYA: PERCEPTION OF WOMEN ON ENTREPRENEURSHIP**

**Peter B. Kibas, Director The KIM School of Management, Nairobi**

## **Abstract**

This study aimed at determining the perception of village women on entrepreneurship success, opportunities and challenges. Women being the backbone of rural economies in developing countries and specifically in Africa, play a significant role to ensure their families' well being. This is seen in terms of providing food, shelter, health and education for the children. Being the majority (55%) of the rural population, their role is crucial in bringing about change in their communities. Most (95%) are engaged in providing for their families through subsistence farming and other agricultural activities supplemented by micro enterprises. Majority (90%) of these women are engaged in these activities out of necessity given that they have limited choices outside their traditional roles. The other reason was the need for financial independence.

The case study methodology was the key approach in this research. The researcher identified and conducted face-to-face interviews and Focus Group Discussions with the women leaders and representatives. The study focused on 50 women groups spread across Mt. Elgon and Bungoma Districts of Western Kenya. They represented Self-help groups operating at the grassroots level and engaged in various income generating activities. A total of 50 women participated in the study. The key research questions for the study examined the perception of the respondents on the following: reasons for engaging in business, success factors, opportunities available for starting micro-enterprises, and the challenges facing women micro-entrepreneurs.

## **Introduction**

Rural entrepreneurship has become more of a way of life and an 'engine' for economic transformation among the rural poor. It is offering hope for the disadvantaged members of society, the majority of whom are women. As they engage in micro enterprises, they operate under what has come to be known as the Informal Sector; a sector with near nil government regulations and policies. Studies however, have shown that women owned and operated enterprises have tended to remain micro with little growth if any. Here in Kenya for instance, it is fairly evident that the woman especially in the rural areas, appear to be marginalised especially with regard to main stream entrepreneurship interventions. The cultural believe that women belong to the kitchen is still strong among most rural people; and anyone who goes against this norm is viewed as an 'outcast' and may be married off as a second wife or may never be married at all.

Apparently, from anecdotal evidence, it has not always been easy for rural women to find suitable jobs that will allow them to balance family responsibilities and employer requirements. Education, training and relevant experience also appear to have been impediments to employment in addition to family expectations. Hence many women are attracted by the idea of self-employment which allows them flexible hours to take care of both the home and business fronts. Micro and small-scale enterprises represent an important means of earning income for the rural women in Kenya (GOK, 1992). They provide a means of livelihood, employment and income to alleviate poverty conditions.

The number of women in entrepreneurial roles has increased significantly over the last three decades. In the 1990's for instance, their overall share of Micro and Small-scale Enterprise Sector in Kenya grew over 70 percent (GOK, 1999); and women being the majority beneficiaries and implementers. These entrepreneurial women however, appear to still lag behind their male counterparts in terms of enterprise growth, income and in general competitiveness. For most women entrepreneurs, going into business was to get a steady source of income and to fend for their families (Karanja, 1996). These women were mainly housewives whose lifestyles have been largely focused on household chores. Many women entrepreneurs were either pushed into business by their spouses or are victims of circumstances such as losing key bread winners in the family. Hence for most of them, business is a necessity rather than an opportunity. This study aimed at determining the woman entrepreneurs perception on entrepreneurship success, opportunities and challenges.

Despite the hurdles faced in operating enterprises, especially in the rural areas, women appear to have managed to pull through and provide basic (sometimes secondary) necessities for their families. Indeed a few of those successful rural women entrepreneurs are seen as role models in the community for their hard work and perseverance. As a result some of them have been invited to give public talks/lectures in the schools and in special gathering in the community. They have also made great efforts in the development process through the formation of self-help and income-generating groups. Studies have shown that success of these women depends largely on the existence of an enabling environment and also on the social and economic factors prevailing at the time (Otunga, et al. 2001). The level of education, training, age and access to means of production also play a major role.

There are a number of financial and non-financial interventions currently in place to support these entrepreneurs (Manen and Koimburi, 2004). They include: micro-loans, business development services, marketing services, and government policies and regulations (GOK, 1996). Most of these interventions however, are only common in urban areas and have not had much impact in most of rural Kenya.

Keino and Ngau (1993) pointed out the changing societal norms and economic environment as some of the reasons for the emerging roles of women. They argued that the traditional gender division of labor has drastically changed and that today women have to work to provide for their households. Food has been identified as the immediate need of most rural households in Kenya. While searching and engaging in activities such as micro-enterprise and other income generation activities to fill this gap, rural women have largely to contend with social, economic and environmental challenges often with scarce resources. Kibas (2001) in the study on the impact of women operated enterprises found that women are now emerging as key players in the economic transformation of their homes. As regards their characteristics, most have hardly gone beyond primary education and have no or very limited training. As regards marital status, 80% are married and have families. A number of these women have absentee husbands, who often work far away from their homes; the rest of the women population are either single mothers, separated or widows.

In a study conducted in Western Kenya, it was evident that these women have only their basic necessities in mind when starting a venture; however, other additional reasons emerge as the business progresses. The purpose of this study was to determine the perception of rural women on entrepreneurship success, opportunities and challenges. Specifically, the study sought answers to the following questions: why are women engaged in business? What are the success factors and opportunities? And what are the challenges in operating micro

enterprises in rural settings? The rural setting was selected because of the size of the Kenyan population which lives outside urban settings; it is estimated to be over 65% of the total population. The significance of the findings of this study is that the government and other key players in development, can now package appropriate interventions specifically aimed at the issues raised by the rural women entrepreneurs.

### **Methodology**

The case study was the primary method of study. Through the case study and blended with descriptive approaches, the researcher gained a rich understanding of the context of rural entrepreneurship. Village self-help groups, which are largely composed of women (90%), were seen as 'cases' that represented a wider population of individuals engaged in micro enterprise to bridge an economic and social gap. The descriptive methodology enabled the researcher to capture a clear picture of how women in the rural environment perceived and engaged in entrepreneurial activities. As noted in Saunders et al (2000), these methodologies are seen as being appropriate for this type of study where the researcher needs to capture an accurate picture of the events as they occur.

The population of interest consisted of all women groups operating in rural areas of Mt. Elgon and Bungoma Districts of Western Kenya. The total population of these organizations in the area of interest was approximated to be over 200 registered and active self-help groups and Community Based Organization (CBOs) in the area of interest. Most (over 95%) of the rural women are engaged in providing for their families through subsistence farming and other agricultural activities supplemented by petty trade or micro enterprises. Agriculture, which is practiced mainly for home consumption, takes various forms such as; keeping chicken, growing vegetables, and tending the family gardens among others. They are also engaged in small-scale horticulture for the market place. A few women keep livestock as part of the family assets as well as savings. Most have hardly gone beyond primary education and have none or very limited training. As regards marital status, 80% of women are married and have families. A number of these women have absentee husbands, who often work far away from their homes; the rest of the women population are either single mothers, separated or widows.

A multi-stage sampling process was used to select the 50 respondents for the study. Through purposive sampling and using a list provided by the Non Government Organizations (NGOs) serving in the region, 50 (25%) women groups were identified to participate in the study. The groups sampled came from different parts of the two districts of interest and covered all the sectors of the economy, which included farming, livestock, chicken rearing, trade and cottage manufacturing. Prior to the sampling, a survey was done with the respective NGOs in the region in order to get a picture of the status of rural entrepreneurship in the area. Preliminary discussions were also made with some of the leaders of the groups before holding in depth Focus Group Discussions with the representatives of the sampled groups.

The researcher conducted face-to-face interviews and Focus Group Discussions with the sampled women group leaders and representatives from the 50 selected self-help groups. The key research questions for the study examined the perception of the respondents on the following aspects: reasons for engaging in business and success factors, opportunities available for starting micro-enterprises and the challenges facing women micro-entrepreneurs. Data was analyzed using qualitative methodologies. This was mainly content analysis. The aim was to establish the patterns, trends and relationships of gathered data on

the perception of rural/village women on entrepreneurship success, opportunities and challenges (Mugenda and Mugenda, 1999). The objective was to understand the women's interpretation and perception of the role of engaging in entrepreneurship activities.

### **Why engage in business and entrepreneurial activities?**

The study found that the key reasons why most women venture into income generation activities such as operating micro and small businesses include: the need to provide items such as food, clothing, education and health care for the family, and to help in the development of the community, among others. Most women also stated that they were engaged in entrepreneurial activities because they wanted to be self-reliant; being self-employed so as to be kept busy and gainfully occupied. They wanted to rely less on their spouses for financial support and up-keep. Studies have also shown that women tend to be more considerate and committed to providing for their families even when it means "toiling like beasts of burden" in fetching firewood, digging, drawing water and cooking, while the husbands do little with no regard to what the family will eat.

Table 1 gives a summary of the reasons provided by the respondents as regards why they were engaged in entrepreneurial activities. Leading among the reasons was, Family Welfare with 20 (45.5%) respondents. This reason included the ability to provide for the family adequately – good shelter, secure home, and education for the children. This reason was followed by the need to be self-employed as indicated by 12 (27.27%) respondents. Self-employment was expected to create some autonomy, generate income, and hence alleviate poverty.

Table 1 about here

From these findings, a pattern seems to emerge. Three key reasons are given why a woman would engage in business or income generation activities. On top of the minds of the rural women, is survival of the family, being occupied by engaging in self-employment and the need to develop the community and the economy. Profit motive did not feature much – only one respondent indicated it as a reason for going into business.

This study found that most entrepreneurial activities operated by the women in the rural area included: operating small retail outlets (often in temporary locations), selling of second hand clothes (*mitumba*) and the marketing of surplus food crops. Few were engaged in farming as a business. This rotated around the practice of agriculture on subsistence. The surplus was then sold to generate income for the family.

### **Success Factors**

Several factors were perceived to be contributing to the success of micro-enterprises in rural Kenya. These include: availability of capital, market opportunities, suppliers of inputs, availability of other resources and good planning. Table 2 provides an analysis of the success factors that would contribute to starting and managing an income generating project as stated by the respondents.

Table 2 about here

## *Capital*

Availability and accessibility of capital for both business start-up and business growth was most common with 6 (27.27%) respondents. It is worth noting that capital requirement for most women operated businesses was fairly low at the micro-enterprise level. It was also ranked first as a critical factor since few women in rural areas can access bank loans. Commercial banks have conditionalities that have often been found to be discouraging; for example the requirement of collateral as security for the bank loans. Most women operating micro-enterprises may not easily acquire loans from commercial banks due this requirement unless their spouses or parents act as sureties. The Co-operative bank and the 'village' banks have however, been in the forefront in innovative micro financing, which has assisted these entrepreneurs.

An emerging type of association has developed in many rural areas, known as the "Merry-go-round" or Rotating Savings and Credit (ROSCAs) Associations. These are usually informal groups that have emerged mostly among the women to fill the void of lack of capital and related social support (Alila, 1996). A group of women often ranging between 10 and 30 organize themselves to contribute money to each other in turns, with the aim of improving their welfare. Most of the money received from these associations usually ends up in the purchasing of household goods, paying school fees/tuition for the children, and in meeting other obligations. A number of respondents who belong to some of these groups stated that they had successfully invested the money in their micro-enterprises. Profits they earned were then largely used to pay off the 'soft loan' from the members.

Most of these women entrepreneurs used their personal savings for initial business start up. This came from previous savings for those who were employed. They also received support both in cash and in kind from their families including spouses, parents, and siblings to invest in the business. Some of the respondents indicated that they obtained their start-up capital from farm produce such as surplus crops, milk, poultry and cattle. A very low ( 2%) percentage of these women however, obtained their working capital from the co-operative bank in form of loans and advances. This low utilization of loans is either because of ignorance, lack of information about loan payments and repayments or because the cooperative banks were not available in some of the locations covered by the study.

## *Planning*

Surprisingly (knowing that these are rural women with limited knowledge) a number, 6 (27.27%), of respondents indicated good planning as one of the key success factors. Planning prior to and subsequently after the business start-up stage was stated as a success factor. Most of the respondents indicated that they had learned from others how to manage the resources in the micro-enterprise effectively. This covered setting objectives and standards, customer care, retention and motivation of staff. Planning to most of them involved preparing for a "rainy day" when it is too wet to do anything.

## *Availability of markets and other resources*

Markets and effective demand for the products and services offered were perceived to be important for the success of the enterprise. Markets were said to be crucial in the survival and take-off stages of the enterprise. Effective demand and good positioning of the products and services offered played a key role in the growth of the enterprise as stated by 5 (22.73%)

respondents. Availability of resources and suppliers were also ranked as important by a similar number of respondents.

### **Challenges facing Women Entrepreneurship**

Asked about the challenges facing rural entrepreneurs, the respondents gave various factors that were said to be posing challenges and impacting on the woman entrepreneur. They included: competition from well established male-dominated enterprises, lack of accurate information on markets, inadequate support mechanisms, finance for expansion, lack of risk-taking behaviour, domestic commitments, and stereotyping among others. Table 3 gives a summary of key challenges as perceived by the women entrepreneurs to be major hindrances to business growth and expansion.

Table 3 about here

Foremost were competition (markets) and information related factors, which were said to be major challenges as stated by 12(32.43%) and 11(29.73%) respondents respectively. Competition was seen in form of the size of the market share in the rural setting – most of these markets were not expanding and new competitors were also emerging; including mini-super markets with wide varieties of products for those who were engaged in selling household products.

Lack of information on the new markets and market segments, and the ever increasing demands by clients for variety also posed challenges to the rural entrepreneur; local entrepreneurs did not have adequate information on markets in which they were supplying their products. Inavailability of accurate information and lack of knowledge about business management were ranked 1<sup>st</sup> as key challenges. Information about the government procedures on micro and small enterprises were not easily available to the respondents. Inadequate resources and support mechanisms from spouses and others ranked 3<sup>rd</sup> with 4 (10.81%) respondents indicating that these were limitations.

The other challenges from the Focus Group Discussions that were seen to be affecting the success of rural micro-enterprises include: need for effective communication so as to negotiate/bargain favourably; management and effective control of debtors and proper record keeping; lack of appropriate skills, and family demands. Issues to do with domestic matters such as balancing a woman's role in the home and the enterprise expectations also featured as major challenges facing women.

In a number of cases, for those women entrepreneurs who sought trading licenses, they found the procedures rather bureaucratic and time consuming. Licenses were only available at the trade offices at the district headquarters. These offices are often far away, in some cases over 30 kilometers from the business location. This was also complicated by poor and unreliable public transportation system which often resulted in one wasting time traveling and waiting for the license to be processed.

The poor infrastructure, which covers the road networks and communication services in a large portion of the rural area of study, was a major obstacle for enterprise growth. It was reported that transportation became ineffective and inefficient due to impassable roads

(especially in wet seasons); hence most fresh produce from the farms often deteriorated before reaching the market – leading to heavy losses every season.

Entrepreneurship always involve some level of risk taking. For women in the area under study, gender stereotyped perception of self, lack of confidence and assertiveness appeared to have been major barriers. Most of the respondents in the Focus Group Discussions concurred that risk taking was a big hindrance and that engaging in the non-traditional and outside home activities were still being frowned at in the village. This was coupled with heavy domestic commitments, and resistance of social structure to change. Family resistance to change so as to allow the women to make major decisions and engage in business is a real obstacle and disincentive to business start-up and growth. The status of women in a patriarchal social structure, of which the area of study seemed to subscribe heavily to the norm, makes women dependent on males in their lives –husbands or fathers. It was also noted that other close male family members often made decisions for women; this usually tended to go against the independent spirit of entrepreneurship.

Lack of sufficient education and training for women was reported to be another impediment to micro-enterprise success. Culturally, and especially in the rural setting, the girl child was not given equal opportunity to study like the boys; hence they had limited education and training (if any) which tended to affect effective performance in later life. One respondent stated thus,

*“ We as women are more isolated socially; we lack previous work experience, and access to enterprise information and marketing facilities which the men entrepreneurs acquire. The excessive demand on our time as wives, mothers and ‘managers’ of the home front due to our chores, make it nearly impossible to successfully operate an enterprise. It is only by God’s grace that we manage to survive. This is besides our position in the family and the structure of power relation; where women are treated as children with no much voice. One who ventures out there to follow the entrepreneurial spirit, often does so at the expense of her family.”*

One other challenge that was cited a number of times, was the responsibility of the entrepreneur to provide for the extended family members and relatives. Most micro-enterprise resources are not usually separated from personal finances and hence these family obligations are met from resources earned in the business. Enterprise income was often diverted to pay tuition, medical expenses services and other expenses on behalf of the members in the extended family. Their demands tended to drain the savings and income made by the business; since such finances would otherwise have been used in the enterprise for expansion and growth. Though some of them do assist in providing services in the enterprise (or in the family), the financial obligations in supporting them usually exceeds the services they provide.

## **Conclusion**

The study sought out answers to the following questions: Why are women in rural setting engaged in business? What are the success factors and opportunities? What are the challenges in operating a micro-enterprise in rural settings? Based on the findings of this study, the following conclusions can be drawn:

1. Women are less concerned with making money. They see entrepreneurship as a means of simultaneously meeting career needs and providing for the family. What they earn is mostly spent for the benefit of the entire family. Another key motivating force for women was to be self-supporting and somehow 'independent' from depending so much on the spouse.
2. Among the key success factors were that generally, women entrepreneurs in rural areas receive substantial family support at start-up and in the course of running their business. Such support is however, based mainly on social rather than economic consideration. Other factors include good planning, availability of markets and resources and suppliers.
3. A number of challenges face rural women entrepreneurs. They include: lack of information on the markets and sources of finance, competition, inadequate management skills, debtors management, domestic issues and cultural practices among others.

From the findings of the study, many rural women are unaware of credit sources and other business support services. They are therefore disadvantaged compared to their urban entrepreneurs.

### **Implications of the study**

The overall implication of this study is that since rural women entrepreneurs appear to be playing a major role in the economy, besides up-lifting the lives of their families, special effort is needed to develop rural entrepreneurship. Hence appropriate and sustained interventions targeted to the rural women entrepreneurs need to be developed and implemented. All the stakeholders, who include the Government, Non-Governmental Organizations, private/corporate sector firms, donor agencies and all the intermediary community-based organizations should be involved. The women entrepreneurs themselves will be expected to more specifically identify the areas of critical support and be involved in the development of suitable programs.

Specifically the following need to be addressed:

1. *Capacity building:* Women need training in functional areas such as finance, marketing, production and managerial skills. This assumes numeracy and literacy skills. Women's involvement in co-operatives requires literacy and education. Illiterate women are shy to join organizations. To become entrepreneurs in single or cooperative firms women first need to understand their own capabilities.
2. *Family Support:* A major strategy should be to promote the social and economic empowerment of women, as they constitute a vulnerable social category that is critical in sustainable development endeavors. Married women should be given support by their spouses in respect of finances, motivation, encouragement, advice and actual involvement in the running of business.
3. *Financial support:* Access to credit by women entrepreneurs at the level of small-scale enterprises, should be facilitated through programs and alternatives that go beyond the conventional collateral dominated credit security systems. The public sector and credit organizations should be sensitized on the value of gender-balanced participation in the informal sector enterprise.
4. *Policy and Regulations:* The government's role in enacting and implementing rural-entrepreneur friendly policies as regards licensing ( for example, having a one-stop shop

office closer to the communities), and security and respect of private property. Gender specific policies sensitive to women entrepreneurs needs need to be developed and implemented.

5. *Infrastructure:* The government together with the private sector and other stakeholders should be involved in improving and providing the road network, communication facilities and the needed utilities such as water, electricity and postal services.
6. *Further Research:* There is need for further social research in the area of culture and women entrepreneurship.

## APPENDIX: TABLES

**Table 1: Reasons for engaging in Business**

| <b>Reason why in business</b> | <b>Frequency</b> | <b>Percentage</b> |
|-------------------------------|------------------|-------------------|
| Family Well being             | 20               | 45.45             |
| Self employment               | 12               | 27.27             |
| Develop the economy           | 9                | 20.45             |
| To be responsible             | 2                | 4.54              |
| To earn Profits               | 1                | 2.27              |
| <b>Total</b>                  | <b>44</b>        | <b>100</b>        |

**Table 2: Success Factors**

| <b>Success Factors</b>                  | <b>Frequency</b> | <b>Percentage</b> |
|---|------------------|-------------------|
| Capital                                 | 6                | 27.27             |

**ABSTRACT**

Family resource management practices of business owning families in Canada, Korea, and The United States are compared. U.S. respondents are 759 family managers in the 1997 National Family Business Survey. Canadian respondents are 65 family managers from Manitoba in the 1997 Canadian Family Business Survey. Korean respondents are 105 family managers interviewed in 2000 as part of a survey of owners of small to medium enterprises in Seoul. Chi squared statistics indicated country differences on each of the ten management practices. Mean responses on eight of the practices were significantly different between countries. Korean and U.S. means were different on all eight; Canada and Korea were different on four of the practices. Factor analysis of the management scale items yielded different patterns for Canada, Korea, and the United States. Both the number of managerial strategies and the types of strategies used varied in the three countries.

Key words: family resource management, business-owning families, family business, cross-cultural comparisons

## INTRODUCTION

While there is universal agreement that the ecosystems approach to family resource management is the most influential currently, questions have arisen about the broad applicability of the Deacon & Firebaugh (1988) ecosystems framework. Engberg (1996) has characterized the dominant approach in family resource management as technical and argued that a technical approach substantially restricts feasible actions in much of the world and should not be used in ethical practice. Zuiker, Stafford, Heck & Winter (1995) have questioned whether the Deacon & Firebaugh (1988) framework is better suited to employment management than to family management or to men's management rather than women's management. To the extent gender roles are more clearly defined and distinguished in less developed countries and nonwestern cultures, the questions raised by Zuiker *et al.* (1995) would, by implication, also raise questions about the application of the Deacon & Firebaugh (1988) framework to the situations in less developed countries. The purpose of the present paper is to compare the family resource management practices of business owning families in Canada, Korea, and the United States as measured by a scale based on the Deacon & Firebaugh (1988) framework. Such a comparison is an essential step in the assessment of the generalizability and usefulness of the Deacon and Firebaugh framework, in particular, and the ecosystems framework, more generally.

## REVIEW OF LITERATURE

Empirical research on family resource management in Canada, Korea and The United States provides little basis for making cross-cultural comparisons or drawing inferences about the applicability of the Deacon & Firebaugh (1988) framework to nonwestern cultures. At most we can compare results across two countries. The effects of resources on family resource management have been studied only in Korea.

The effects of gender have been studied only in The United States and Canada. In Canada, Duncan (2000) found that men and women spent different amounts of time on household management. In the United States, Zuiker *et al.* (1995) found that men and women managed families differently. Korean interviews on family resource management have been with women.

The effects of domain have been studied in Canada and the United States, and in both countries the effect of domain was tied closely to the effects of gender. In the United States women managed family and paid work differently, but men did not. In Canada the evidence for a domain effect on management was less direct. Women used home-based work and self employment to balance the demands of employment and family, but men did not, and women who had home-based employment spent more time in management than women who did not.

The effects of number of demands on family resource management have been studied in all three countries, but the same indicator variables have been used only in two countries. Results for number of demands were inconsistent between Korea and the United States and within Korea. In Korea, number of children had a negative relationship with family resource management, but in the United States number of children had a positive effect. In Korea, while number of children had a negative effect, wife's employment had a positive relationship with management. In the United States, number of demands had a consistent, positive relationship with family resource management. Number of children had a positive effect. So did being the family manager and the business manager rather than only the family manager. In Canada, number of demands was indicated by whether employment was home-based or office-based. Time spent in management increased with home-based employment for women.

The relationship between family resource management and satisfaction was researched in Korea and the United States. Again, the results are not comparable. In Korea style of management was related to satisfaction, but in the United States there was no relationship between the quantity or frequency of management and satisfaction. In Korea, morphostatic managers reported the highest levels of satisfaction with family life. In the United States, family resource management behavior did not have a significant effect on either satisfaction with how well children were doing or overall satisfaction with life.

No studies have used the same means of measuring management in more than one country. The current study does. The current study also has the advantage of being based on an internationally respected management framework. Consequently, the results of the current study will enlighten both the subject of cross-cultural differences in management and the subject of the cross cultural applicability of the framework used as the basis for the study.

## **METHOD**

### **The Family Resource Management Scale**

The current study uses the 1997 Family Management Scale, which is based on the Deacon & Firebaugh (1988) model. The 1997 scale is an updated version of the 1992 Household Work Scale (Heck, Winter, & Stafford, 1992) first developed as a summary measure of the practices described in the Deacon & Firebaugh (1988) model. The 1992 scale was developed as a summary measure of the entire set of behaviors covered by the term "family resource management" that could be administered via telephone interviews and used in causal analyses. As such the scale could not contain numerous items and had to be readily understood. The 1997 modifications were prompted by previous results that suggested the words used to operationalize the managerial behavior did not have the same meaning for women as they did for men. Other research suggested that the statement, "Each week you decide some way you can improve your life" in the 1992 scale was not satisfactory in operationalizing the concept of goal setting. Therefore, in the 1997 scale the wording of this item was changed to "Each week you decide something specific you can do for your

family.” The specific wording of the scale items and the managerial concepts they represent are presented in Figure 1. For each item, the leading statement was “These next items are about how you manage your household. Think of a scale from 1 to 5, where 1 means the statement is not at all like you, and 5 means it is exactly like you.” In pretests conducted by the Iowa Statistics Laboratory, a random sample of respondents did not have difficulty rapidly understanding and evaluating the family resource management scale items.

Scores on each of the 10 scale items were summed to give a total management score, which could range from 10 to 50. Higher scores on individual scale items denote more frequent use of the practice that conforms to the Deacon & Firebaugh (1988) model of family resource management and, therefore, are assumed to be associated with more effective management. It was assumed that the higher the score on the household management scale, the more extensive the management practiced by the respondent.

[Figure 1 about here]

## **Data**

The data for the United States are from the 1997 National Family Business Survey (NFBS). The NFBS contains data from both the family manager and the business manager from a nationally representative sample of business-owning families. To be eligible for inclusion, a household had to consist of two or more persons related by blood, marriage or adoption, at least one of who owned or managed a family business. The business owner had to work in the business at least 300 hours a year and have been in business for at least a year. Detailed information on prevalence rates can be found in Heck & Trent (1999). Detailed information on data collection methods and procedures can be found in Winter, Fitzgerald, Heck, Haynes & Danes (1998).

Data for Canada were obtained from a representative sample of 65 business-owning families in the province of Manitoba. Data were collected in 1997 simultaneously with the NFBS in the United States using the same definitions of business ownership and household as criteria for inclusion in the sample. The same interview schedule and procedures were used for the Canadian and the American samples. Both data sets were collected by the Iowa Statistics Laboratory.

Data for Korea were obtained from a representative sample of business owning families in the city of Seoul. Whereas, data from Canada and the U.S. were collected by telephone interviews, data from Korea were collected via face- to- face interviews in January, 2000. Only the family managers of business owning families were interviewed in Korea. They answered questions about both the family and the business. Korean respondents were selected from the small business directory published by the Korean Small Business Association. The 1997 NFBS served as the foundation for the interview schedule used in the 2000 Korean Family Business Survey. Questions from the NFBS were translated into Korean, administered in Korean. After the data were coded, both the interview schedule and the coded data set were translated back into English.

### *Samples*

The sample for the United States is 759 families who completed the family manager interview. Of those 259 were dual managers, managing both their families and a business. The remaining 500 were single role managers. In Canada 61 family managers completed the family interview. Of those, 17 were dual role managers and the remaining were single role managers. All 105 of the family managers in Korea had a dual role, also working in the family business with their spouses.

Several descriptive characteristics of the business-owning families ( $n = 925$ ) are shown in Table 2. The average age of the household manager was 45. The mean of educational level for the household manager was 14 years. Over half of the business-owning families owned home-based businesses (51%), they have resided in the community for 19 (19.3) years, and about 55% lived in a rural location (towns of 10,000 or less). Most of respondents (89%) owned their home.

On average, the number of children in the household was 1.40, the number of children present aged 0-5 in the household was .23, and the number of children present aged 6-17 in the household was .85, number of total children under 18 years old was 1.04. The average total family income was \$ 68,419, income from the family business was \$ 31,351, and family income from other sources was \$ 37,203. On average, the number of working persons in a household was 2.02. For the large majority (71.8%), the business was owned and managed by the first generation.

[Table 1 about here]

### **Analysis**

Frequency of responses for the 10 statements comprising the 1997 Family Management Scale were tested for independence using the chi square statistic. Also for each statement in the scale and the total management score the mean response was calculated. An F-test for difference in means for each item and the total management score was used to discover whether the three groups of managers differed significantly in their managerial activities. Pair-wise differences in means were tested for significance using the Scheffe and Bonferroni tests. Cronbach's alpha and a standardized item alpha were used to assess the reliability of the 1997 Family Management Scale for each of the three countries. Finally, factor analysis of the Family Resource Management was conducted separately for Canada, Korea, and the United States. While tests for independence and difference in means identified intercountry differences for each item and the total management score, principle components factor analysis with varimax rotation was used to discover underlying relationships among the items in the management scale and differences or similarities in the underlying relationships among the three countries.

## RESULTS

### Differences in Management Practice by Country

The results of tests for independence indicated systematic differences in response to the management items by country. The Chi Squared statistic for each item was significant at the .05 level or greater. Canadian home managers were as likely to reply with a four as with a five. Korean home managers were more likely to reply with a three or five rating rather than with a four. Americans were most likely to reply with a rating of five, and were more likely to reply with a four than with a three. According to the F tests, mean responses were significantly different for eight of the ten items in the management scale. Only the mean responses for demand clarification and resource assessment were not significantly different. According to the Scheffe and Bonferroni tests, mean responses for all eight of the other items were significantly different between Korea and the United States. There were fewer significant differences in responses between Canada and Korea. Canada and Korea had significantly different mean responses to the items for sequencing, standard setting, adjusting and demand responses. Mean responses were not significantly different between Canada and the United States.

[Tables 2 & 3 about here]

### Factor Analyses of the Household Management Scale

Factor analysis of the management scale items yielded different patterns for Canada, Korea, and the United States. Both the number of managerial strategies and the types of strategies used varied in the three countries.

#### Canada

Four identifiable factors resulted from the analysis of the Canadian data. Canadian household managers are plan oriented, goal oriented, action oriented or outcome oriented. Standard setting, demand clarification, resource assessment and checking comprised the planning orientation. Plan oriented managers know how they will judge the outcome of their managerial activities before they begin, they ensure that their goals are clear, and they know how much of their resources can be devoted to their goals. These managers also associate checking with these planning activities; checking appears to be focused on ensuring that goals are clear and resources are adequate.

Goal oriented managers emphasize goal setting, adjusting, and demand responses. These managers set goals and associate goals with how well they like the results. That is, how people feel about achievement of goals is important to these managers and adjusting – finding another way to accomplish the goal when plans are not progressing well – is the link between initially setting the goal and achieving satisfactory results. Resource issues do not appear to be a primary concern for these managers.

Action sequencing and actuating load together for action oriented managers. These managers emphasize getting things done. Their managerial activities are focused not on setting goals or monitoring resources and outcomes but on the actions themselves. Planning when to take action and taking action are the key strategies for these managers. Finally, monitoring resource changes is the only managerial activity to load on the factor that describes action-oriented managers. For these managers, the primary focus is on the effectiveness of their managerial activities. Unlike their goal-oriented counterparts, these managers do not appear to focus on satisfaction with goal achievement as much as efficiency of goal achievement.

## **Korea**

Three factors resulted from analysis of the managerial practices of Korean household managers. Korean managerial styles were identified as classic, goal oriented, or action oriented, but the goal oriented and action-oriented styles differ from those of their Canadian counterparts.

Classic managers use the planning activities of demand clarification, and resource assessment; the implementing activities of checking and adjusting; and the output activities of demand responses and resource changes to manage family life. Setting goals is not an emphasis for these managers; rather, it appears that the goals are already known and the focus instead is on being sure that the goals are clear and that resources are sufficient to meet goals.

Plans are checked and adjusted as necessary as they progress in order to achieve satisfactory outcomes. Satisfaction with both the extent to which goals are met and resource use in achieving goals are important to these managers.

The second managerial style evident among the Korean managers is a goal-oriented approach. Unlike Canadian goal oriented managers who associated goal setting with adjusting and demand responses, Korean goal-oriented managers pair goal setting and standard setting. For these managers, deciding which goals to pursue and how to judge if the goals are met drive management.

Finally, action-oriented managers focus on the managerial strategy of actuating. Korean action-oriented managers focus simply on taking action, whereas the Canadian action oriented managers paired putting actions in sequential order with taking action. For Korean action-oriented managers, it is the actions themselves that predominate.

## **The United States**

Analysis of the US sample yielded two identifiable factors. U.S. household managers can be described as process managers and technical managers. Process managers are focused on satisfaction with the outcome of managerial activities. These managers see close associations among the components of planning, standard setting and action sequencing; the implementing activities of checking and adjusting; and the output of demand responses. For these managers, satisfaction with the results is crucial, so standard setting, that is, having a good idea about how to judge the outcome of their managerial processes, is an important activity. Like the classic managers in Korea, these managers check their plans to see if everything is all right and make adjustments if necessary in order to achieve a satisfactory outcome.

In contrast, production managers monitor resource changes, not demand responses. These managers are concerned with the effective use of resources, not feelings of satisfaction with the output. Production managers associate goal setting, goal clarification, resource assessment and actuating with resource changes. They think plans through so that goals are clear and required resources are identified. Taking action is associated with these activities as well. Production managers have a clear focus on resources.

[Table 4 about here]

## **DISCUSSION**

Consistent differences between pairs of countries were found. There were differences in frequencies, means and factor loadings. Before discussing cultural differences in family resource management, it is necessary to acknowledge the possibility of other explanations for the differences among countries reported in this article. In particular, sample characteristics and measurement error may partially explain differences in results. In the middle section the meaning of cultural differences in management will be discussed. Finally, implications for future research will be discussed.

Several differences in sample characteristics may be related to the differences in means between countries. The Korean families were all dual earner; in fact, both spouses worked in the family business. Only Korean women were interviewed; both family information and business information were provided by women who managed the family and worked in the business. In the United States only 25 or 34 percent of the sample were dual role holders. In Canada, 17 or 28 percent were dual role holders. Previous studies of family management by business owning families in the United States found that dual role holding by the family managers was associated with more extensive management. In the absence of cultural differences, the larger proportion of dual role managers in the Korean sample would have explained higher management scores for the Korean sample. However, most often Korea had the lowest score not the highest. A potential explanation for this result will be discussed under measurement error.

The Korean respondents were all urban; the sample was drawn only from Seoul. The United States and Canada had large proportions of the samples drawn from rural locations. The greater distances between houses in rural areas may be associated with more extensive management. However, rural incomes are lower than urban incomes in the United States, and lower income may lead to substitution of labor for capital in the form of more extensive management. Therefore, differences in the urban/rural composition of the samples may be responsible for some of the observed differences in mean scores.

Finally, the Korean respondents all owned first-generation family businesses and all were very small businesses. In the United States most, but not all, of the businesses were very small. In Korea, only 13.3% of the respondents owned a home-based business. In the United States and Canada the proportion was much larger. In the United States 55.9% of the respondents and in Canada 61.8% owned home-based businesses. The managers of families with home-based employment in the (Heck, Winter & Stafford, 1992) reported lower management scores, whether dual or single role holders, than the managers of business owning families in the 1997 NFBS, whether dual or single role holders (Duncan, Zuiker & Heck, 2000). In the absence of cultural differences, these previous results would imply higher management scores for Korea rather than lower scores.

One other possible explanation for the differences in results between Korea and The United States and Canada is measurement error. In both the United States and Korea there is evidence of response bias, a tendency to give the same response to the next question as given to the last questions. Interestingly, there may be a cultural difference in the preferred answer rather than the extent of the bias. Koreans most frequently responded with a neutral three; whereas, Americans most frequently responded with a five, exactly like me. The preponderance of neutral responses is found in other Korean survey results. To some extent, the bias toward a neutral response may be mitigated in this study by the use of a Korean interviewer who interviewed the respondents in Korean. The difference in preferred response may be cultural. Americans may be more likely to think they are supposed to say they manage. The question that needs to be asked is whether the observed differences are cultural differences in management practice or cultural difference in perception of the desirability of managing a family.

The remaining explanation for differences between countries is culture. Assuming the observed differences are real and attributable to culture rather than sample characteristics, is the Deacon and Firebaugh systems model of family resource management more applicable to Western cultures than to Eastern cultures? Possibly the answer is yes. The model was developed in a Western culture, and is an outgrowth of empirical studies of management practices of Ohio family managers thought to be managing well by their friends and neighbors. Other cultures were not included in the development of the model. On the other hand, the perennial, persistent problems of families are universal and techniques that make the work of families more efficient should be applicable across cultures. The environment and amount of change the families encounter may be very different from one country to another. Consequently, the prevalent management practices and routines may be different from place to place.

Taken together, these results strongly suggest that further international comparisons of the managerial practices of business owning families are warranted. Relational analyses that control for sample characteristics would help determine to what extent cultural and sample characteristics are responsible for the observed differences in managerial behavior. It is also important to control for the environments of these families in future research. It would also be valuable to identify attributes of the cultures that explained differences in management practice, assuming the differences are found in the future to be attributable to culture.

Another direction for future research suggested by these results is use of different model of family resource management. Stafford & Avery (1991) suggested a family resource management model that would be more broadly applicable than the Deacon & Firebaugh (1988) model yet was consistent with the family systems model on which Deacon & Firebaugh (1988) based their model. To date this model has not been used in empirical research. Perhaps use of their model to guide measurement of managerial behavior patterns would facilitate cross- cultural research. More consistent results might lead to less controversy about the relevance and applicability of western management techniques to nonwestern cultures and the techniques used in developed economies to less developed economies.

FIGURE 1

Family Resource Management Concepts <sup>a</sup> and Corresponding Questionnaire Items

| Management concepts  | Questionnaire Items <sup>b</sup>   |
|----------------------|--|
| <b>Input</b>         |  |
| Demands              |  |
| Goal setting         | Each week you decide something specific you can do.  |
| <i>Events</i>        |  |
| <b>Resources</b>     |  |
| Throughput           |  |
| Planning             |  |
| Standard setting     | Before starting a complex task, you have a firm idea about how to judge the outcome.   |
| Demand clarification | When planning a task, you think the plan through so that your goal is clear before you begin doing the task.                 |
| Resource assessment  | Before you begin a job, you figure out how much of your time, money, and energy that you can devote to this particular task. |
| Action sequencing    | You think about when to do a task, and not just how much time it will take.  |
| Implementing         |  |
| Actuating            | When there is a task to be done at home, you wait until the last minute to do it. <sup>c</sup>                               |
| Controlling          |  |
| Checking             | As you work, you check whether things are going as you want them to.   |
| Adjusting            | When things are not going well, you figure out another way to do it.   |
| <b>Output</b>        |  |
| Demand responses     | When a task is done, you think about how well you like the results.  |
| Resource changes     | You are pleased if the work just gets done; you do not spend time thinking about how effectively it was done. <sup>c</sup>   |
|                      | You are pleased if the work just gets done; you do spend time thinking about how effectively it was done. <sup>d</sup>       |

<sup>a</sup> Management concepts refer to definitions used in Family Management: Principles and Applications, by Ruth E. Deacon and Francille M. Firebauth, Boston: Allyn and Bacon, 1988.

<sup>b</sup> Actual items are listed. The leading statement was: These next items are about how you manage your household. Think of a scale from 1 to 5, where 1 means the statement is not at all like you and 5 means it is exactly like you. Items were not asked in the order listed.

<sup>c</sup> This item was reverse coded in descriptive statistics and the factor analysis results.

<sup>d</sup> This item of Korean data was not reverse coded in descriptive statistics and the factor analysis results.

**Abstract**

This paper explores business planning by small and medium enterprises (SMEs) owners dedicated to management development in Australia. Planning in large organizations has been studied extensively but with little applied to SMEs. Research has shown that planning pays and there is a renewed focus on planning by SMEs. The success and growth of SMEs is of utmost importance to world economies. Business planning has been considered as a management undertaking that can lead to success and growth. This research investigates types of business plans that are important for SMEs and factors that influence planning and the key issues and concerns of management in planning. In undertaking the study it was expected that those who do engage in formal management processes would be more of planners than those who do not engage in the same. A total of 350 structured questionnaires were sent to the respondents by mail and 156 usable responses were received indicating a response rate of 44.6%. Results from this study indicated that some key management issues are more relevant to SMEs and therefore would be helpful to entrepreneurs and SME managers to undertake them as opposed to others in their business planning. The results also indicated that not all entrepreneurs view business planning as being important. The size of an enterprise, level of education of the entrepreneur and type of industry an enterprise is in was found to greatly influence the level of planning while age of an enterprise did not have an influence on planning.

## INTRODUCTION

Small and medium enterprises (SMEs) form significant sectors in most world economies and therefore their development is regarded as an important issue for most governments. The significance of the sector is due to the contribution made to job and wealth creation in the world economies (Hodgetts & Kuratko, 2001). According to the International Labour Organization the sector accounts for over 40 percent of private sector employment. In Australia, SMEs produce about one-third of total Gross Domestic Product of the economy (Meredith, 2000) and represent about 85.5% of all Australian enterprises including public trading and general government organizations (Office of Small Business, 1999). In the United States of America, small enterprises employ 57 percent of the private sector workforce and produce approximately 45 percent of the nation's gross national product (Helms & Renfrow, 1994). Contributions to world economies by SMEs include provision of opportunities for innovation and breeding grounds for new business ventures (Meredith, 1988), producing national output and exports and reducing rural-urban migration through decentralization and employment generation (Kiriri, 2002).

Although SMEs are a vital part of most economies, there has been much concern about the high failure rate of SMEs mostly attributed to management issues. This has led researchers to examine causes of the high SME mortality and suggest possible solutions to success. For the success of any attempt to prescribe a diagnosis to SME problems there is a need for researchers to understand the pertinent activities engaged by entrepreneurs and contrast them with those that ideally would contribute to the success of SMEs. Business planning has been identified as one factor that would contribute to good management practices and thus lead to success of SMEs.

## LITERATURE REVIEW

Most studies on planning have focused research on larger organizations and as such, have assumed SME owners automatically work with planning models and theories which are not based upon or formulated specifically for SMEs (Shuman, Shaw & Sussman, 1985). However, researchers who have studied SMEs business planning have characterized SME planning behavior as unstructured, irregular, and comprehensive, and as incremental, sporadic, and reactive (Sexton & Auken, 1985). SME knowledge on strategic planning has been argued to be inadequate and not popular amongst owners/managers because SMEs have neither the time, nor staff to invest in planning (Robinson & Pearce, 1984). Primary objective of most SME planning has been found to be related to financial obligations either debt financing, refinancing of current debt or to obtain venture capital (Singhvi, 2000). In his survey of SMEs in UK Singhvi found that 70% of the surveyed companies prepared a business plan primarily for financing needs. Other reasons that he found out were when seeking expansion of current business and developing exit strategies. This is contrary to the expectation that planning would be used to assist in operations and management of an enterprise.

SME planning is influenced by various factors including enterprises' size, age, industry type and education level of entrepreneur or key managers. Over the years researchers have noted a firm's size as a primary influence of business planning. From a meta-analysis conducted by Schwenk and Shrader (1993), it was observed that firm size and stage of development were critical factors in planning. As firms grow and diversify, it becomes progressively more difficult for management to maintain intimate knowledge of industry and business conditions and to exercise control through informal procedures and hence the need for more structured decision making

frameworks incorporating planning (Chae & Hill, 2000). Small firms and those at the earlier stages of growth differ in planning with large firms in later growth stages as a result of difference in resources, specialist expertise and impacts on the market place (Gibson & Cassar 2002). Firm size is measured using several dimensions, which include number of employees, sales turnover (Berman, Gordon and Sussman, 1997) and asset value. Of these the most commonly used and easier for researchers to obtain and validate is the number of employees (McMahon, 2000; Kiriri, 2002). However, it is advisable to use sales turnover as a second measure as it would help overcome misleading employee related size measures as a result of use of independent contractors and part time staff (Gibson & Cassar, 2002).

A firm's age or the length of time the business has been in operation has also been found to influence planning. Risseeuw and Masurel (1994) reported that planning intensity decreases slightly with increasing firm age suggesting that firms that are in the early life cycle stages may show high planning intensity as a result of uncertainty of the future and in an effort to secure financing for the start up phase. Previous research has also found differences in planning behaviors among various industries (Berman, Gordon & Sussman, 1997; Glen & Weerawardena, 1996) suggesting that firms in some industries would include more planners than in others. Gibson and Cassar (2002) found support for this though a weak one in that retail, accommodation and cafes industry appeared less likely to have a business plan. The decision-makers level of education has also been found to greatly influence the levels and incidence of planning. Research by Lowe and Clemens (1991) in Australia found that the incidence of planning was greater when the major decision-makers' education level was high. This is supported by Lee and Matthews (1999) who argue that education is positively related to business

planning. Recent research by Kiriri (2002) and Gibson and Cassar (2002) in Australia give more credence to this. Both studies found that decision-makers with a tertiary qualification were more inclined to be planners than the others. Of interest, Gibson and Cassar (2002) observed that of those with tertiary degree, the likelihood of planning was higher if the qualification was business related.

While some researchers have hailed planning as important to the success of any enterprise, others have argued against it especially long term planning. Planning has been accused of stifling creativity and eliminating true vision and synthesis from the process of change and yielding to too much rigidity. Management theorists such as Henry Mintzberg argue that planning by its nature is prone to devolving into an overly rigid focus on analysis and quantification becoming innately inflexible and incapable of predicting crucial market shifts or encouraging adaptation to current market conditions (Mintzberg, 1994). While some researchers have called the planning-performance relationship tenuous, others have concluded that planning may not be necessary at all while others have argued that planning may actually hinder firm performance (Lumpkin, Shrader & Hills, 1998).

Researchers who have undertaken studies on SME planning formality have drawn conflicting conclusions with some claiming that formal planning provides structures for decision making, helping SME managers take a long-view that benefits their firms. Others conclude that formal planning has no potential pay-off for SMEs because it is a heady, high-level, conceptual activity suited solely to large firms and therefore has no benefits for financial performance of SMEs (Schwenk & Shrader, 1993). Informal planning is prevalent in most SMEs but for most firms,

growth brings with it increasing pressures to formalize the planning process (Chae & Hill 2000). In order to address growth pains brought about by evolution and revolution crises in firm's growth stages, formal planning becomes cardinal.

Empirical support for the usefulness of planning has been mixed. Berman, Gordon and Sussman (1997) found a positive relationship between formal planning and financial performance of firms and concluded that firms that plan produce better financial results than firms that do not plan. As generally agreed planning is a good management practice and firms that don't plan are not as effectively managed, as they could be (Gibson & Cassar 2002). Nevertheless, other studies have found no relationship between planning and performance in small firms arguing that due to limited resources, firms in the early stages of growth are more likely to enhance performance through informal application of strategic decision-making practices than through formal business planning (Schwenk & Shrader, 1993; Lumpkin, Shrader & Hills, 1998). There is however some reported increased interest in planning among SMEs (Kuratko & Hodgetts, 1998).

### **SME BUSINESS PLANNING IN AUSTRALIA**

Planning practices by SMEs in Australia has tended to be similar to other developed economies of America, Canada, and Japan. According to a survey conducted in Australia by Goodwin and Hodgett (1991), it was found that 82 percent of all SMEs responding stated that they do prepare a plan. According to Goodwin & Hodgett (1991) planning in most SMEs in Australia is not influenced or dependent on the number of employees. Most SMEs in Australia that plan are found in the service sector where education levels may be higher and where the industry is rapidly changing to a greater extent than in the other sectors of the economy (Lowe & Clemens,

1991). A study by Kelmar (1996) found that majority of the firms surveyed were undertaking strategic planning activities though most performed these activities on an informal *ad hoc* basis. Kotey (1995) also found that the planning process in small firms as intuitive and informal, involving very little documentation of details of operations.

Most small business owners in Australia believed that undertaking business planning activities benefited their businesses through an increase in sales (Kelmar, 1996). However, Kotey (1995) in studying planning, enterprise performance and owner/manager personal values, concluded that owners/managers placed little emphasis on planning and where planning was undertaken, attention was focused on issues affecting the immediate survival of the business. In a study of planning performance versus planning comprehensiveness of small firms in Australia, Devenish and Fisher (1994) found that firms that undertook strategic planning tended to be larger than those that did not.

### **TYPES OF SME BUSINESS PLANS**

Different authors have suggested different types of plans for SMEs. English (1998) classifies business plans for SMEs as *strategic plans* concerned with creating a strong competitive advantage, meeting the demands for change and constructing a business strategy; *operating plans* concerned with day to day processes, procedures, workflow and efficiency; and *financial plans* representing the dollar quantification of strategic and operational plans. Stoner & Fry (1985) suggest two basic classifications of business plans for SMEs. *Working plans* designed to guide and control actual business operations which include strategic plans; tactical or operating plans and functional plans such as marketing, finance, manufacturing or personnel and *investments/financial plans* designed for the sole purpose of obtaining financing from banks,

government agencies, creditors and other sources of financing. Other researchers refer to specific plans based on *functional* areas of management for a planning enterprise. The business plans, which will be a focus of this study, include marketing/sales plan, organizational plans, human resource/people plans, succession plans, external financial plans, internal financial plans, feasibility plans and strategic plans.

## METHODOLOGY

Data for the analysis were collected from SMEs registered with Business Enterprise Centres (BECs) in Northern New South Wales, Australia. These are government-established agencies to assist in the start up and growth process of SMEs in New South Wales. Convenient non-sampling method was used to select the samples for the study as this allowed selection of respondent based on personal judgment. Use of convenient sampling allowed the inclusion of potential business firms and also allowed the inclusion of those who had been in business for a long period of time. Another consideration was the need to have a sample drawn from a cross-section of businesses in diverse industries. BEC managers in the region of study were allowed to select at least 30% of their members to participate including those who had attended business start up courses in readiness to launch their own businesses. A sample of 350 SMEs was selected from 10 BECs. In selecting the businesses from the region to include in the survey, the respondent firms had to fit into the definition of SMEs of the Australian Bureau of Statistics (ABS, 1999) as:

***Small business:*** Those businesses, which are not subsidiaries of another company and are neither public company, unincorporated cooperatives nor incorporated associations and employ *less than* 20 Full Time Equivalent (FTE) persons. ***Micro business:*** Consists of those small businesses

employing *fewer than 5* Full Time Equivalent (FTE) persons. **Medium business:** Consists of those businesses that are not small businesses, but employ *less than 200* people.

A pre-tested questionnaire was sent by mail. Evidence suggests that a mail survey compared to other methods, is relatively cheap, much information can be obtained very quickly without the problems of interviewer bias and variability inherent in face-to-face techniques, degree of respondent anonymity is assured and sensitive information can be easily gathered in this way, where specific data are requested and records and other sources can be sought for verification (Forsgren, 1989). The questionnaire contained two sections. The first section contained demographic information on the respondents and their enterprises while the second section included questions related to business planning practices. Respondents were asked to indicate:

1. Whether they engaged in planning or not.
2. For those who did plan a list of 8 business plans derived from a literature review on plans for SMEs was provided and the respondents had to select plans that they undertook.
3. All respondents were required to rate the importance of various business plans on a scale of 1-7.
4. A list of 17 business activities derived after a literature review were presented and the respondents were required to indicate how important the various key management concerns were for their businesses on a scale of 1 – 7 (from ‘not important’ to ‘extremely important’).

A total of 156 questionnaires were returned providing an overall response rate of 44.6%.

Descriptive analysis and multivariate tests were used in this study. Descriptive analysis provides means and percentages for the various computations. Multivariate analysis of variance is used to

test whether there is any significant difference between the ratings on importance of plans and factors influencing planning. Univariate tests are further used to show the significant difference between various types of plans and influencing factors.

## **RESULTS**

### **Characteristics of sample members and their enterprises**

The demographic profile of the 156 responding SMEs indicates that a wide variety of businesses participated in the study. The distribution of businesses and their owners' demographics represented a good cross-section of Australian SMEs as evidenced from studies conducted by the Australian Bureau of Statistics (ABS). There is no much difference in representation between this study conducted in the northern part of NSW and data representing the whole of NSW as conducted by the Australian Bureau of Statistics (ABS) in June 2001 (ABS, 2001).

In general respondents were well distributed across age and education. There is a noted male over representation (73.1 percent) compared to females (25.6 percent). This does not differ significantly with ABS data where male were 69.1 percent and female 30.9 percent of the respondents. The survey sample indicated that majority of the business owners/managers were mature aged with very few SME owners under 29 years (4.5 percent versus ABS 11.8 percent) while those between 30 – 50 and over 50 years were the majority with 60.9 percent and 32.7 percent respectively (57 percent and 31.2 percent for ABS data). Most of the respondents attained a high school level of education (44.2 percent against 39.3 percent from ABS data). However, those who had some college training either at TAFE or university were 54.5 percent of the total sample (60.7 for ABS data). Of the 156 respondents 78.2 percent were either business owners or partners while 19.2 percent were managers. It was a requirement that either a business

owner, partner or key manager involved in decision making in the business answer the questionnaire.

Most of the SMEs in the study were limited liability companies (40.4 percent), while partnership and sole proprietorship represented 32.1 percent and 22.4 percent. Most of the enterprises had been in business for more than 5 years (75.6 percent). The industry breakdown indicates an emphasis towards wholesale/retail business at 45.5 percent, with service enterprises representing 30.1 percent and manufacturing and construction enterprises at 14.1 percent and 5.8 percent respectively. Approximately 81.4 percent of the enterprises had less than 10 employees. Annual sales turnover levels were fairly evenly distributed with 17.3 percent having less than A\$ 100,000; 19.2 percent having between A\$100,000 and A\$ 300,000; 18.6 percent having between A\$300,000 and A\$ 500,000; and 39.7 percent with over A\$500,000.

### **Business Planning Status**

In determining respondents who had business plans and those without, a descriptive frequency analysis was performed. The results indicated that 116 enterprises (74.4%) undertook some business planning while 40 (25.6%) did not produce any business plans. In considering the actual business plans undertaken, an analysis of the survey responses as presented in Table 1 shows that 53.8% of the respondents undertook internal financial plans and 54.5% marketing/sales plans. About one-third prepared organizational, staffing and strategic plans. At the other end of the scale, only 13.5% engaged in succession plans, 20.5% in feasibility plans and 22.4% in external financial plans.

---

Table 1 about here

---

### **Importance of Various Business Plans**

Respondents were asked to rate importance of the 8 business plans on a scale of 1 – 7 (from ‘not important’ to ‘extremely important’) regardless of whether they engaged in planning or not. As presented in Table 2, majority of the respondents had the opinion that marketing/sales plan and internal financial plans were the most important of the eight alternatives. The respondents viewed succession plans and organizational plans as the least important.

---

Table 2 about here

---

### **Factors Influencing Planning**

A multivariate analysis of variance was performed to investigate influences on planning. The eight business plans were used as dependent variables while enterprise owner’s education level, industry, enterprise size and age were used as the independent variables. Preliminary testing conducted to check for multivariate assumptions noted no serious violations. The results indicated an overall significant difference between the importance of business plans and education level ( $p=.014$ ), industry type ( $p=.006$ ) and enterprise size ( $p=.001$ ). There was no significant difference in ratings the importance of business plans and age of the enterprise. Further, in order to investigate ratings on importance of specific business plans, a one-way analysis of variance (ANOVA) was undertaken. As evidenced in Table 3, the level of education attained significant differences with ratings of five business plans while type of industry and enterprise size each had two.

---

Table 3 about here

---

## **KEY MANAGEMENT CONCERNS (KMCs)**

In planning, various business activities are undertaken. In total, 17 key management concerns (Table 4) involved in planning were presented to the respondents who were required to indicate how important various key management concerns (KMCs) were for their businesses on a scale of 1 – 7 (from ‘not important’ to ‘extremely important’). The reliability of the scale was tested using the Cronbach alpha test and was found to be reliable with an alpha of .9394 (Hair et al. 1995). The responses on KMCs were subjected to a means analysis. The mean of each of the KMC was computed and ranked. Table 4 presents the key management concerns and responses on the importance of KMCs to their businesses ranking based on the highest means. The five most important KMCs ranked on means revealed that marketing, sales issues and financial issues were KMCs for most of the respondents. On the other hand, the least important activities included organisational structure, succession issues, market feasibility studies, manpower planning and outlining lines of authority and delegation.

---

Table 4 about here

---

### **Key Management Concerns – Factor Analysis**

The 17 KMCs variables were subjected to principal component analysis. The aim of conducting factor analysis was to summarize the 17 variables into a smaller number of factors for use in further multivariate analysis (Hair et al. 1995). Principal component analysis revealed the presence of three components with eigenvalues exceeding 1, explaining 52.1%, 8.3% and 6.8% respectively accounting for a cumulative variance of 67.2%. An inspection of the scree plot revealed a break and leveling of the plotting after the third component. By using Catell’s (1966) scree test three components were extracted and retained for further investigation.

To aid in the interpretation of the three components, a Varimax rotation was performed. Table 5 presents the rotated solution. The rotated solution revealed the presence of a simple structure with the three components showing a number of strong loadings, and all variables loading substantially on only one component. An examination of the components reveals some relationships between the variables.

---

Table 5 about here

---

Factor 1 loads heavily with activities related to finances and the future of the business. This factor can be seen to be a **financial and strategic construct**. Factor 2 loads heavily with activities related to personnel issues and organisational issues. This factor then is related to organisational of human resources and can be interpreted as a **human resource construct**. Finally, the 4 activities that loaded on factor 3 related to pricing, products, promotion, market research and competition, which are issues of concern in the marketplace. This factor can be seen to be more of a **marketing construct**. The three constructs were tested for reliability using Cronbach alpha coefficient. All the components were reliable as they attained the required alpha levels of above .5 with Coefficients ranging from .78 to .91 reinforcing the reliability of the constructs (Nunnally 1970).

### **Key Management Concerns Constructs and Planning Status.**

The three constructs derived from the principal factor analysis were subjected to a further multivariate analysis of variance (MANOVA) with the planning status variable (those with plans and those without). The essence of the MANOVA analysis was to assess whether there was any significant differences in means between those who plan and those who do not on the three key management concerns factor composites.

The MANOVA results revealed that **overall** there were significant differences ( $F= 9.420$ ,  $P=.000$ ) in means ratings on the 3 constructs between those who plan and those who do not plan. An investigation on the individual components revealed that all three constructs had significant differences in means between those who plan and those who do not (Table 6). Those who plan rated highly the business activities engaged in planning than those who do not plan and therefore the significant differences in their means. This implies that those who plan rated highly the constructs indicating planning as more important to their businesses than those who do not plan.

## DISCUSSION

As noted earlier 74.4% of the total respondents engaged in business planning. This is a high percentage but consistent with other previous studies on planning by SMEs in Australia.

Goodwin and Hodgett (1991) found that 82% of their total sample engaged in business planning. The high rate of planning can be attributed to the high education levels of the respondents (54.5% had at least a college education). In a study on planning by small firms in Australia, Lowe and Clemens (1991) found that education levels greatly influenced the levels of planning. From the analysis, the majority of the respondents engaged in marketing/sales plans (54.5%) and internal financial planning (53.8%). This could be attributed to the role played by these plans in the operations and survival of the enterprise.

Marketing/sales plans define enterprise customers and possible strategies to the achievement of set goals. In order to operate profitably and track down performance, internal financial plans are

widely undertaken by most enterprises as through them an entrepreneur can get information and guidance for making operational decisions about the business (Stoner & Fry, 1985). A study conducted in the United States of America by Shuman, Shaw and Sussman (1985) found that the areas in which most plans were prepared were marketing/sales 67.3 percent, operations 22.9 percent, finance (external) 4.2 percent and engineering 3.7 percent. Kiriri (2002) in a study on business planning found that activities related to marketing and financial operations and planning were rated as the most important key business activity entrepreneurs undertook. This gives credence to the finding that most entrepreneurs view marketing/sales plans and internal financial plans as the most important plans.

Due to the size and operations of most SMEs organizational plans are generally not viewed as important since they determine type and designs of organizational arrangements required in implementing other plans (Van de Ven, 1981), which may not be a priority to most SMEs. People/staffing plans were averagely rated which indicates that most SMEs find them of some importance. The least popular plans with the respondents were external financial plans (22.4%), feasibility plans (20.5%) and succession plans (13.5%). The reason could be that these plans are prepared at certain times/periods in the life of an enterprise. External financial plans are mostly prepared for the sole purpose of obtaining funds and presenting to shareholders and other stakeholders however, this is an exception for most SMEs. Potential entrepreneurs would ideally prepare feasibility plans before they begin business operations as well as existing entrepreneurs to evaluate the viability of a new enterprise, product or project. This would rarely occur during the lifetime of an enterprise. Succession plans are required for the succession of the business yet

most businesses do not plan for succession, which may lead to failure (Brown & Coverley, 1999; Hodgetts & Kuratko, 2001).

Consistent with previous research and as mentioned earlier, education levels are deemed to have influence on planning. Those who have a high level of education are therefore expected to be planners in contrast to those with a lower level of education. This can be inferred from the fact that most SME owners fear the formality of planning and do not think there are benefits to accrue from planning. Size of an enterprise also has influence on planning. It would be expected that the larger the enterprise, the more the resources to plan and increased situations that demand planning as a management tool. It would also be expected that smaller firms due to their size do not have time, staff, and expertise to undertake planning. The small enterprises may not recognize benefits accruing from planning and in most cases are a 'one man show'. Enterprise age on the other hand did not attain a significant level. Age is therefore not seen as a key influencer on planning. However, it would be expected that as a result of the learning/experience curve effects, older enterprises would be more of planners than the young.

An analysis of the key management concerns shows some relationship with the ranking of the most popular plans. Activities pertaining to marketing and finance were highly ranked by all the respondents. From the factor analysis of the key management concerns it was evident that those who plan attained a significant difference as opposed to the non-planners, which clearly delineates the key activities undertaken by planner's vis-à-vis non-planners.

The results from this research should form a background for further research on SME business planning. The fact that the respondents rated various business plans as important does not show or indicate what they meant by 'importance'. It should therefore be investigated further as to the value that the various business plans add to enterprises. Previous research has shown that business planning does pay and largely contributes to the success of SMEs but falls short of indicating what plans are ideal or important and contribute to the success of an enterprise. SMEs would have different planning needs depending on their stage of development/growth. Further research is also required to indicate what types of plans would be ideal to any planning enterprises at their different life cycle stages.

## **Small business policy and entrepreneurship promotion – a comparison of the contextual framework in three European countries**

Rita Klapper, Associate Professor, ESC Rouen, Bd Andre Siegfried, 76130 Mont St. Aignan, France, Tel. 0033232825838 Fax. 0033 232825833

Across the European Union there has been an increase in the number of programmes and initiatives aiming to promote small business and entrepreneurship (for a discussion of programmes and initiatives see Commission Européenne (1998), Commission of European Communities 01.03.2001). In line with this general trend, small business and enterprise creation are increasingly recognised as vital for European economies such as Germany, the United Kingdom and France and programmes and initiatives have been tailored to promote these issues in both national and regional economies.

To date, little research has focused on the framework conditions for small business and entrepreneurship and even fewer studies are of a comparative nature. This paper aims to fill this gap in the literature by drawing on the experience from international research into small business and entrepreneurship in the UK, Germany and France. The paper intends to kick off with a short exploration of the theoretical background to small business and entrepreneurship, followed by an account of the development of these related concepts in the three countries and a subsequent analysis of the key determinants that seem to impact upon the development of small business and entrepreneurship.

Little research has given consideration to the national differences in the socio-economic and political framework in which small business and entrepreneurship exist. The research reported upon has highlighted a number of key determinants which are responsible for the development, or rather the lack of development, of both the small business sector and entrepreneurship in the countries under question. Some of these factors may be rooted in the type of economy promoted by the individual countries, some of which may relate to the education system, some of which may relate to the role of the government. In the case of Germany we can see for instance that the social market economy laid the foundations for an active 'Mittelstandspolitik' which was adopted by the end of the 1950s (Lane 1995). In fact, the intellectual heritage of the social market economy in Germany can be traced to the Freiburg school of neoliberalism, a group of liberal economists who as early as the 1930s began to look for alternatives to the increasing market intervention of the Third Reich

(Smyser 1992, Willgerodt & Peacock 1989). In the post world war II period, economists such as Walter Eucken, Alfred Müller Armack and Ludwig Erhard thought neoliberalism to be a better solution to Germany's problems than the planned economies of the East and their views strongly influenced government policy makers (Peacock & Willgerodt 1989, Pickersgill & Pickersgill 1985, Sauer 1984, Wiseman 1989). Whilst steady growth, employment, high productivity and high incomes were important considerations, it was competition which became the focal point of his policies aiming at the promotion of small business and the development of an entrepreneurial spirit in the German economy (Sauer 1984).

Whereas in Germany the support framework for SMEs has developed against the backdrop of a relatively young social market economy, in the UK support for small business emerged as a response to the publication of the Bolton Report in 1971 and the framework of an enterprise culture as promoted under the Mrs Thatcher's administrations from 1979 onwards (Bannock & Albach 1991). Crucial to an understanding of the development of the enterprise culture in the UK is the recognition of the role of the Conservative administrations, in particular those led by Margaret Thatcher in the 1980s (Peck & Tickell 1992, Westhead & Moyes 1992). Stone (1991) and Wilson (1990) have noted that it was the Thatcherite governments that sought to change almost every facet of the post world war II economy and its management. The driving force was the strong belief that a thorough-going restructuring of the economy and revived economic growth could only be achieved by exposing the nation's industries, workers and social institutions to the full rigour of unfettered market forces (Martin 1989). This presented a significant departure from the philosophies of earlier years. In order to 'de-rigidify' the economic structures, government policies aimed to privatise public industries and services, curb trade union power, de-regulate markets, and promote individualism and self-reliance. In particular, the latter characteristics became extremely important for the development of an 'enterprise economy' which aimed to place explicit emphasis on the rejuvenation of small business (Burrows 1991a, Goss 1991). As Abercombie & Keat (1991) argue there were two pillars to Thatcherite economic ideology; the promotion of large multinational financial institutions and the small firm sector that epitomises individual entrepreneurship and innovation.

The trend to promote small business growth and entrepreneurship has also been continued during the second term of the UK government under Tony Blair and Harding (2003) argues

that entrepreneurship and innovation have become synonymous with the present UK governments policies towards productivity, regeneration and growth.

In comparison, the emphasis on small business and entrepreneurship is still a relatively recent domain in France and the research in this field has to date failed to mobilise the French scientific community (Fayolle 2000). In fact, interest in small business and entrepreneurship is underdeveloped in France (Girard 2002). In particular enterprise creation by Higher Education graduates is a very marginal phenomenon in France compared with countries such as the United States as highlighted by Fayolle (1999a,b) and Bechard (1994). According to the 'Observatoire des Pratiques Pédagogiques en Entrepreneuriat' (Observatory for pedagogical practices in entrepreneurship (OPPE)), there were only 60,000 people who were younger than 30 years old and had created their own company in 2001 (Lecherbonnier 2002). However, building upon the recent interest in entrepreneurship the new French government under Jacques Chirac and its Prime Minister (Premier Ministre), Jean-Pierre Raffarin, (former Minister for SMEs) aims to encourage interest in entrepreneurship and business start up in French society (Girard 2002), with the underlying aim being the optimistic intention to create one million enterprises over the next five years.

The research has shown that in all three countries certain key factors seem to have influenced the development of small business and entrepreneurship. In Germany the social market economy, the federalist system, a public-private partnership approach and the promotion of technology due to a strong engineering culture have certainly favoured the promotion of small business and entrepreneurship. In addition, there is the pressing need to find solutions to the economic problems of the Eastern part of Germany and a recession that has hit both East and West Germany that have added urgency to the promotion of small business and entrepreneurship. Conversely in the UK a laissez faire approach favouring an enterprise culture as well as a predominantly top-down approach to policy making with some input from the regions, as well as a focus on voluntarism, self-help and managerial solutions seem to have worked in favour of small business and entrepreneurship.

Examining the key determinants for the low interest in small business and enterprise creation in France the research has identified the role of the state in promoting large corporations as well as the nature of the education system which has aimed to train senior managers needed for the large state-run conglomerates as actual barriers. In addition, an attitude generally in

favour of public sector employment and a cultural background which seems to be anti-entrepreneurial seem to discourage small business and enterprise creation.

# **FINANCING STRATEGIES OF WOMEN SMALL BUSINESS OWNERS**

Deborah Knowles

Westminster Business School, University of Westminster, UK  
d.s.knowles@westminster.ac.uk

## **Abstract**

Financing is a vital aspect of business start-up. Women small business owners may find this a particularly challenging task for a number of reasons. The literature categorises funding as external – in the form of loans, grants and venture capital funds and business angels - and internal from, for example, personal savings. Of these two types, external funding receives the greater research attention. A contested issue in the area of the financing of women's businesses is that of discrimination on the part of banks.

A great deal of the research on the financing strategies of women entrepreneurs uses a quantitative paradigm which demonstrates the prevalence of women's use of the various types of financing opportunities. This "reduced length paper" introduces data from a qualitative study of women entrepreneurs which shows not only the types of business financing chosen by women entrepreneurs but also attempts to provide an understanding of these choices with the use of their own explanations for this behaviour.

It is found that many of the women used varying types of personal funds, not because they experience discrimination in the loan application process but because they prefer to avoid debt. Use was made of the Government Enterprise Allowance Scheme. Loans were often from sources other than banks, and although banks were used by some, despite a very small amount of reported discrimination, this was a source about which dissatisfaction was expressed.

It is recommended that funding institutions create innovative funding solutions to accommodate women's preferences.

## **Introduction**

Business financing, particularly at the start-up phase, is an activity which is often cited as presenting particular challenges to women (Carter & Cannon, 1992; Carter. et al, 2003; Fay & Williams, 1993; Greene et al, 2001; Still & Guerin, 1991, Turner, 1993). The small number of previous studies which consider the demand side of the financing of women's businesses compare women entrepreneurs' financing choices with their human and social capital (Carter et al, 2003; Greene et al, 1997) or with the choices made by men (Johnson & Storey, 1993, Rosa et al, 1994).

A number of perspectives seek to explain why women-owned businesses may be unlikely to make use particularly of debt financing opportunities. The financing strategies of women starting up businesses are determined firstly by the amount of funding needed and secondly by the availability - or rather perceived availability - of different types of funding.

Discrimination against women in the financing of their businesses is well-documented in the case of the granting of business loans (Fay & Williams, 1993; Koper, 1993; Still & Guerin, 1991) and may restrict women's choice in this area. Thirdly, funding sources are chosen according to the preferences of the entrepreneurs themselves, which are established by learning including that from previous experience and upbringing (Coleman, 2000).

This "reduced length paper" draws on a wide-ranging, partly longitudinal, qualitative British study of women's entrepreneurship behaviour to introduce data on these choices and

their background in terms of the types of funding used, the reasons for these choices and the women's own preferences.

## **Background**

Research interest in women's entrepreneurship is increasing with the growth in women's entrepreneurship itself (Greene et al, 2001). In the UK currently approximately 26% of self-employed people are women and their businesses generate approximately £130 billion (\$250 billion) turnover (Smith, 2004). However, much of this academic interest has until recently been focused on women's circumstances and their motivations for starting up businesses, rather than *how* they go about this. Studies of the types of funding that may be used by women has generally viewed this activity from the supply side, that of the financial institutions, rather than the demand side of the women entrepreneurs themselves (Greene et al, 2001).

Business owners use a range of financing methods. These may be categorised as those from external sources such as loans from banks, other public institutions including government schemes, or individuals; grants from business start-up programmes established by government or large corporations; venture capital funds; business angels and trade credit and those from internally raised funds such as personal savings (Carter et al, 2003; Hooks, 2003). Of these two types, the external funding sources receive greater research attention, possibly due to their more visible and transparent nature and because there are two parties involved in the transaction. Carter et al describe a hierarchy of entrepreneurial financial strategies. At the bottom of this scale entrepreneurs fund their new businesses with personal savings, bank loans or government schemes (either singly or in combination). On the next rung as businesses grow they use a bootstrapping approach. Bootstrapping techniques involve using personal or internally generated funds, controlling costs and delaying capital expenditure and make use of, for example, retained earnings, leasing of equipment, advances from customers and second mortgages. These measures are taken in order to build the business to increase its attractiveness to external equity investors (Carter et al, 2003). The use of the hierarchical image suggests that there may be greater merit in the rungs above the bottom since capital is an important element in business success (Coleman, 2000).

Studies which compare male and female business owners vary as to whether women entrepreneurs feel discriminated against by lenders (Carter et al, 2003). This discrimination may be due to institutional perceptions that women lack the necessary motivation and ambition to succeed in business. Bank managers, who are usually men, are found to have 'little confidence' in women business owners and even when they do grant them loans often require a husband's formal agreement (Kaur & Hayden, 1993:103). Johnson and Storey (1993) point out that a finding that women do not suffer from discrimination at the hands of banks merely serves to illustrate that women who have been successful in starting up businesses do not seem to have suffered such discrimination. However, a study comparing bank debt according to firm size finds that small firms are the lowest users of this type of financing for reasons relating to a lack of established reputation – as these businesses are also by far the newest in the sample - which may lead to rejection in the loan application process due to a low credit rating (Hooks, 2003). As women's businesses tend to be smaller than those owned by men, they are more likely to suffer this form of discrimination (Coleman, 2000; Greene et al, 2001). Women have also been found to start businesses with less initial capital funding than men (Rosa et al, 1994, Greene et al, 2001).

Haines et al's (1999) conclusion from their comparison of a number of characteristics of men and women who have been successful in business loan applications is that there was no bias against women. They attribute earlier research findings that banks discriminate against women to faulty research design.

Whereas claims of bias on the part of banks usually depend on accounts related after the event, Fay and Williams (1993) report an experiment to test whether women suffer discrimination in the granting of business loans. Men and women were found to be equally likely to receive a loan where both were graduates; although the level of education was felt to be more crucial for a woman than a man; where education had ended at High School level a woman's application was found to be less likely to be successful. Two experiments carried out by Buttner and Rosen (1992) showed, however, that women were not discriminated against at all in loan applications.

An important effect of the prevalence of the belief that banks discriminate against women in the granting of business loans is that it may act as a deterrent to some women against seeking such funding (Haines, Orser & Riding, 1999; Johnson & Storey, 1993, Richardson & Hartshorn, 1993). The focus of Greene et al (2001) on the gendered nature of success in gaining venture capital provides a similar image of perceived discrimination by investors against women entrepreneurs for reasons of small firm size and also the choice of industrial sector – women tend to start businesses in the service and retail sectors whereas venture capitalists prefer to invest in IT, medical and communications businesses. Nelton (1998) reports on US schemes designed to make venture capital more available to women entrepreneurs and to encourage them to access it. One of the contributors confirms these sectoral and firm size barriers by advising that in order to succeed in acquiring such funds firms must be “high-growth, high-profit business[es]” in which venture capitalists see a potential to achieve a “substantial multiple” of their investment (p. 4).

Personal savings account for a large amount of the capital available to women starting up businesses. This may be a result of experiences of discrimination, women's rejection of debt capital as they are risk averse and prefer to avoid responsibility for large loans or because characteristics of their businesses such as small size or being in sectors with low barriers to entry may make funding affordable from personal resources (Coleman, 2000; Greene et al, 2001).

This qualitative study discusses women's financial strategies alongside their explanations for these choices, problems encountered and observations made at later interviews after an interval of three years.

### **Research Design and Methodology**

Data for this paper is drawn from a partly longitudinal, qualitative, empirical study of women entrepreneurs carried out in the English region of East Anglia, between 1995 and 2000.

A total of 149 women business owners returned questionnaires detailing business and personal information. This material was used to form the illustrative sample of forty-eight women entrepreneurs who took part in the interview stages of the study. They had started up businesses between 1958 and 1996.

The first wave of semi-structured interviews took place in two groups in 1995-6 and 1997. These extremely wide-ranging interviews lasted from thirty-five minutes to two and a half hours, with a usual time of approximately one and a half hours. The interviews were recorded both as field notes and on audio tape.

Amongst a number of topics, the women explained in depth the issues surrounding their financing decisions. This may be analysed in the context of their experience of discrimination on the part of banks (Kaur & Hayden, 1993), perspectives on debt and to business risk in general (Coleman, 2000) as well as other aspects of their experience such as previous start-up ventures (Carter et al, 2003), motivations to start up businesses and attitudes to business growth (Carter & Cannon, 1992), levels of education (Carter et al, 2003; Fay & Williams, 1993), likelihood to have written a formal business plan (Carter & Cannon, 1992) and the types of networking relationships, advice and training they had used (Lloyds Bank, 1997; Marlow & Strange, 1994; Travers, Pemberton & Stevens, 1997). This paper focuses on the issue of financial strategies and the reasons for these choices. Three years later the first interviewees took part in a second interview. With the aid of a written “summary” of the first interview provided by the researcher, the participants refreshed the data and reflected on some of their earlier concerns. (See Knowles, 2002 for a fuller discussion of the longitudinal aspect of the study.)

### **The Findings**

These women’s businesses had been started up and sustained using a variety of personal sources, grants and debt capital. Venture capital and business angels were used by only a very small number of the women. Twenty-five (52%) of the women used personal funds at start-up. In seventeen of these cases this money covered all the costs of establishing the business. Reasons for using one’s own personal funds varied. Two of these women started up by working at home so that there was no noticeable financial outlay.

Molly Poulter<sup>1</sup> started a book shop in 1988 with two women partners who both later left the business. Each of the women contributed £3,000 of personal funds. A bank offered a £5000 loan but this was not used. Molly commented:

“It was a very sensible way to start. We started with the minimum that we could get away with so we didn't pay interest to anyone and we didn't borrow and we bought things when we could afford it and we're still doing that.”

Despite the wish not to pay the additional costs associated with loans, Molly and her partners had made strenuous efforts to obtain a loan in case it might be needed:

“The banks we negotiated with went round and round in circles. [We tried] all of them [laughs]. Two or three times. We ended up with Barclays because they gave us the best deal. We got two years' free banking. You go to one and you say ‘Well, X has offered me’ so they undercut that and you build up. It's absolutely incredible, I don't think people realise.”

In contrast to Molly’s positive experience, when Christine C. started a financial business with her husband their decision to use personal funds was fuelled partly by a poor relationship with their bank:

“We used our own resources. We don't even have a bank account actually.” [laughs]  
We did have but we fell out with banks. They charge too much so we just run a building society account. We fell out with the bank because they wanted to charge us bank charges. And when we had an account with four, five figures in it we felt that they should be paying *us*.” [laughs]

Many of the women specified the source of their personal funds such as redundancy (severance) payments (three cases), the sale of a house (three cases) or land in the case of a horticultural business located on a family farm. Some had purposely saved money from earnings in order to be able to start up businesses. Fay T. had received advice about available loans before starting up her software training business in 1989 but did not follow up these opportunities. She saved £1000 for equipment plus enough money to live on for a year. She said:

“You have to know yourself. I can’t bear debt – it would take me down as an individual. ”

A participant running a secretarial business shared this view that debt was to be avoided:

“I had no wish or desire to borrow. It doesn’t sit with me personally.”

Another woman who had saved money that she was prepared to risk in the business start-up was Alma P. Commenting on her budget of £3,000 for her domestic employee agency, which was located in her own home, she said,

“I was prepared to risk that amount; if it was all gone I would have to pack the business in.”

Although Alma encountered no problems in this as she cut costs by working at home and was able to afford “the basics that any business would need”, the benefit of hindsight showed her ten years after her 1985 start-up that this had been a much greater risk than she had thought at the time.

Christine attributed the survival of her business in partnership with her husband when many “went to the wall a few years ago” to the fact “that we had the house [including business premises], we didn't have [business] rent to pay, and we didn't have bank loans”. This factor in business success was cited by a number of women and is rarely mentioned in other in other studies.

The concept of personal funds was extended in a number of ways by the women. Firstly, as we have seen, many worked from home. Seventeen (35%) lived and worked in the same premises. Secondly, women would continue to work elsewhere for a short period during the initial start-up period.

Thirdly, women would take very small salaries from the businesses. Molly Poulter was one of the extreme cases of this as she took no income at all from the book shop. Molly appeared untroubled by the lack of financial reward for her work, after all before starting up the book shop she had worked for seventeen years in an important role as a volunteer, only succeeding in recruiting her replacement by raising funds to create a paid post. In the book shop she was in a similar predicament: the business was very successful with her unpaid at the helm but, aged sixty-three at our second interview, she was hoping to retire and a successor would expect to be paid. In that interview Molly spoke of closing the shop if no-one came forward to take over.

One of the benefits of the longitudinal aspect of the study was that not only could the development of the participants’ businesses be followed but also it provided an opportunity to correct erroneous data. In the case of Mrs Brewster, the owner of four businesses in the catering and retailing sectors, her main concern at the beginning of the second interview (which took place after she had sold one of her businesses) was to amend what had been written in the “summary” of her first interview. She had mentioned that her husband was a

farmer and that she helped with his clerical work but it was not clear that she was not taking a salary out of her own businesses:

“ ...I mean if you said to me, ‘does your money come from the business’, I would say, ‘yes’. Because it comes from the farm. But we don’t actually draw any salary or any money whatsoever out of Grange House, the Motel or Hintons, it comes from the farm. We thought that was a better, you know, then you don’t take from every one. We take so much per month out of the farm.”

A second important form of non-debt financing in this study is grant aid. The Enterprise Allowance Scheme (EAS) was a government programme (now no longer in existence) set up in 1982 (a time of high unemployment in the UK) with the objective of assisting the business start-ups of unemployed people who might be deterred by the consequent loss of unemployment benefits in the early period before the business had become sufficiently profitable to pay them an income. The allowance was set at £40 per week for up to a year. To be eligible applicants had to be unemployed and receiving state benefits for at least thirteen weeks and able to invest at least £1000 in the business (Industrial and Commercial Training, 1982). At prima facie this scheme seems to discriminate against especially married women as in many cases they are ineligible for unemployment benefits in their own right. However, in a study comparing the financing of businesses owned by men and women, Carter and Rosa (1998) found that women were more likely to use the EAS than men. They attribute this frequency to the women’s subordinate position in the labour market, the fact that more of them had previously been unemployed and, most tellingly, their youth, which suggests that they were unlikely to be the sort of married women against whom the EAS discriminated.

Although the EAS was mentioned as a source of start-up funding by five of the participants in this study there is no way of knowing how many women might have started up in business but for their ineligibility for these means to do so.

One recipient of the EAS also used a number of other types of funding to finance her start-up in a children’s clothing business. She was the only member of the sample to benefit from the Prince’s Youth Business Trust (PYBT). It was this latter type of funding that gave Patti T. the impetus to start her business in 1993 as she had been hoping to use her extensive training in clothing design to join a large fashion house. However, at a time when the PYBT was offering assistance to people up to the age of twenty-five<sup>2</sup>, Patti, aged twenty-five knew that she should take this chance to start up a business as there was no sign of a job offer. She received a PYBT market research grant of £250 which did not commit her to starting a business, a PYBT loan of £2500 at a lower interest rate than a loan offered by a bank, and a £2500 grant from the Livewire organisation (supported by Shell Oil) as a result of being placed 4<sup>th</sup> in a national competition for new businesses. Additionally, her overheads were reduced as she was able to work at her parents’ house and she took a very small salary out of the business. The competition prize boosted Patti’s confidence in her ability to set up a viable business but initially she had been very fearful about accepting the PYBT loan,

“I had no money, no collateral, no car. If the business failed I couldn’t pay the loan back. I didn’t open a business bank account for a month because I was scared about paying back the money. Someone from PYBT phoned me to ask why I hadn’t cashed the cheque.”

Patti returned to the subject of financing the business in the second interview three years later, still at her parents' house. Her very first statement on being asked if there had been in major changes in the business since the first interview was the following:

“The biggest one is that I don't own the company any more. We're Fashionistas *Ltd*. I own forty-nine percent and I sold the rest to an investor .... I needed money for production, which is still a major problem but this was the only way of doing it because I had no collateral. I couldn't get loans from banks.”

Patti had worked hard; she was exporting to many parts of the world and had moved production abroad to cut costs. However, another aspect of business financing had not changed. Asked whether she was now taking a salary from the business, Patti said:

“I have been until recently but we're at a bad time of year waiting for retailers to pay us and they're not. What they're doing at the moment is paying us in small quantities, dripping us a bit at a time.”

Debt financing in the form of loans and mortgages was used by eighteen (38%) of the sample. This number includes four who used loans from family members, twelve who used banks, and one who used a small loan from Norfolk County Council. Mrs Brewster's start-ups in 1958 and 1965 were financed by borrowing from a family trust fund and a loan from “an individual” (unknown to her) which was arranged by a solicitor. The start-up costs of Anne B's business, which was started as a Management Buy-Out, were paid back to the previous owner over a period of time. This financial arrangement like three others used the entrepreneur's home as security. A further two of the participants would have lost their homes if they had defaulted on mortgages on business premises where they also lived. Two of the women, who had started businesses in 1985 and 1989 respectively, reported that far from discriminating against women, banks made gaining access to loans extremely easy for “this was the boom 1980s, banks were giving money away hand over fist” (Interview 41) and “at that time banks were throwing money at businesses” (Interview 25). However, relationships with banks were not always good even for the business owners who accepted the responsibility of a loan. Geraldine B, the food manufacturer, was extremely unhappy with hers. She said that she felt as though her “hands and feet were tied by the bank”.

Not all those who were not using bank loans had decided against them from the outset. Una G. was running a recycling business. At start-up in 1991 she was hoping to use a loan to double the funds she had gained from the sale of her previous business. The six banks that she tried either rejected her application or offered terms that she was unwilling to accept due to what she perceived as prejudice that was wider ranging than simple sex discrimination:

“Unfortunately because the financial institutions consider recycling to be a bunch of greenies who've just got together for the afternoon, *and* I was the wrong sex, they weren't really prepared to lend me any money. But as it turns out I'm not really bothered about it.”

Varied bootstrap funding techniques were used at different phases of businesses. There was no suggestion that these strategies were used, as implied by Carter et al (2003) to enhance the attractiveness of the business to future equity investors. Many of the women entrepreneurs in the study were able to avoid debt by using these techniques at the very outset in a number of ways. When Sarah C. started an upholstery business in 1994 in a

partnership with another woman and two men, the contributions of personal funds from all four partners were augmented by income from existing contracts that had been won while the group was searching for premises. Sarah was aware that the company would need further financing to fund expansion and was considering joining forces with a similar business to work collaboratively. She commented: "None of the partners is very keen on banks." The two Suffolk magazine publishers in the study were also able to use bootstrapping techniques from the beginning. Lydia V., starting up in the grounds of her own home in 1989, found that the business financed itself "from day one". Eleanor J. had an overdraft facility at the bank but did not need to use it as the first quarter's rent in 1996 was paid from business income. Felicity S., starting out in a software writing business in 1989 found that an existing contract provided all the financing needed. Bootstrapping was used by a larger number of the entrepreneurs to fund later business needs. Lynette O started her children's clothing business with money raised from the sale of her house and her later, slow expansion was paid for with cash earned by the business.

In some cases bootstrapping would not provide enough for later financial needs of the entrepreneurs. Belinda S provided the most striking example of discrimination on the part of a bank. She applied for a bank loan of £12000 to buy out her partner and purchase some computers. She was refused the loan after being subjected to a series of interviews, which included questioning on whether she was planning to start a family,

"In the end they offered me £5,000, which was just pointless, and my husband went out and got a private loan for ten grand and that was what saw me through."

The final type of financing in Carter et al's (2003) hierarchy is equity finding. This was very rarely found in the study. The businesses were mostly very small and as we have seen in the case of Patti T, acceptance of external funding was considered almost as the loss of one's business. Frankie P's perspective was different, possibly because her housewares business had gone through a number of legal formations since start up in 1986. Her original partner retired in 1991 and was bought out, the resulting sole trader business became a limited company in 1993 and then a new director joined in 1997. During the course of this a business angel made a 22½% investment in 1992. Frankie experienced no problems with this at all.

The second interviews which took place three years later showed that financing strategies had no bearing on future business survival and success.

## **Discussion**

This study contributes to the research which demonstrates the heterogeneity of women's entrepreneurship experience. Women may be distinguished according to their beliefs and practices in the area of business financing. Many of the women entrepreneurs used a number of financial sources in combination at start-up and later. The most prevalent form of financing was personal funds, which in some cases entailed using large amounts of savings or working at another job alongside their entrepreneurial activities. Many women seemed to choose to sacrifice themselves in terms of risking money saved, working harder or forgoing a salary in order to nurture their business. In this way some of the women appeared to adopt a caring relationship to their business which promoted its survival at any cost to the owner. Focused comparative research on businesses owned by both genders would demonstrate whether this attitude is part of a uniquely women's way of business ownership. Personal funding was used as an alternative to debt or to reduce the amount of a

loan that might otherwise be required. This finding suggests that some women entrepreneurs are debt averse, in concurrence with previous research which has found that women are less likely to use business loans than men (Coleman, 2000). Debt was avoided for reasons of a personal dislike of owing money or to free the business from what was seen as a burden.

Some the participants were able to access grant funding. One of them was well provided with grants and a low-cost loan. Her reluctance to accept the loan suggests that she was instinctively a debt avoider.

The issue of sex discrimination on the part of banks was rarely addressed. Only one woman felt that she had experienced this. Others spoke of poor relationships with banks that were associated not with gender but with the fact that these institutions showed more concern for their own profit than for individual circumstances so that they levied bank charges on large accounts or made business customers feel that their hands and feet were tied.

Despite the possibility that many married women would be ineligible for such aid; the EAS was a popular form of non-debt external funding (Carter & Rosa, 1998). This was seen as a risk-free financing strategy.

Bootstrapping strategies were used at start-up as well as in later phases of businesses.

Business angels and venture funding were used by a very small proportion of the sample. These types of external funding were viewed differently depending on perspective. One participant described the experience of having sold 51% of her business to an investor in tones of regret in the second interview; a second accepted the contribution of a business angel as part of the changeable nature of her business.

A benefit of the longitudinal aspect of this research is that business survival and success may be tracked and compared with financing strategies used: there was no foundation for an assumption that a willingness to use debt funding or external investors would lead to an enhanced likelihood of survival or greater success. However, the findings that many women entrepreneurs are averse to the perceived risks of using loans and that going without a salary is perceived as an acceptable financing strategy indicate that there is scope for banks and other loan making institutions to introduce creative financing strategies that would ease the burden of business financing for such women.

# ONLINE AUCTION ENTREPRENEURS: SOME EXPLORATORY RESEARCH INTO POSSIBLE PARADIGMS FOR ONLINE AUCTION PROCESSES AS AN ENTREPRENEURIAL TOOL

Ian Knox, Centre for Regional Innovation and Competitiveness, University of Ballarat, Victoria, Australia

## Abstract

This paper examines one emerging facet of entrepreneurial approaches, that of the online auction. Online auction sites such as eBay are rapidly becoming a hub of entrepreneurial activity. Ebay boasts 105 million users in 150 countries. At any one time there are 25 million listings on eBay, with 3.5 million new ones added every day. An eBay survey of its sellers, estimates 430,000 people make a large part of their income from eBay. The popularity of online auctions is well documented, but the behaviour pattern for many would-be sellers and buyers is not. A host of entrepreneurial side businesses are also emerging to list items on behalf of third party sellers. German-based *Dropshop* is an example, with an initial 2004 public listing raising €9 million. This paper investigates the emergence of online auction entrepreneurs, with particular emphasis on the nature of online auction selling. A case is presented that above average recommended retail prices for goods are achievable in an online auction environment, providing potential entrepreneurs with unique opportunities.

## Introduction

The global marketplace is changing rapidly, and in turn the definition of entrepreneurship continues to evolve. Alstete (2002) suggests that definitions need to precisely describe who creates new business opportunities for the manufacture of goods and services. Shane and Venkataram (2000, p.220) define the field of entrepreneurship as:

The scholarly examination of how, by whom, and with what effects opportunities to create future goods and services are discovered, evaluated, and exploited (Venkataram, 1997). Consequently, the field involves a study of sources of opportunities; the processes of discovery, evaluation, and exploitation of opportunities; and the set of individuals who discover, evaluate and exploit them.

A significant increase in the study of entrepreneurship has yielded specific qualities or factors related to entrepreneurs that identify them in greater society (Alstete 2002). Alstete further proposes that much literature examines established or failed entrepreneurs, but little focuses on nascent or potential entrepreneurs who may or may not proceed to start a business based on their perception. The characteristics of established or would-be entrepreneurs may not be the same factors that motivate nascent or potential entrepreneurs. What effect has the emergence of changing economic, social and technological conditions had on the desire of individuals to establish new businesses?

It is argued in this article that the online auction phenomenon has provided opportunities for potential (and established) entrepreneurs to exploit the technology in new and innovative ways that would not have been possible in an offline environment. Colombo and Delmastro (2001) established that in addition to a desire for higher incomes, Internet based entrepreneurs wanted to innovate and work independently of corporate cultures. To-date research interest has focused on the technological entrepreneur rather than the exclusively Internet based (cyber) entrepreneur (Carrier and Raymond, 2004). In this context exploratory research into the activity of online auction entrepreneurs would seem appropriate. The popularity of auctions is evident in terms of users (buyers and sellers) and because of the diversity of complimentary, support and peripheral services they have spawned.

There are a large variety of online auctions falling into two broad categories. Third party auction sellers such as eBay, Amazon and Yahoo! auction goods for others (either individuals or corporate), and direct auction sellers create their own auctions online via their company web sites (Halstead and Becherer, 2003). Many large retailers and catalogue firms are using direct auctions to unload merchandise and drive sales. As the use of the Internet for online purchases continues to grow, interest in both types of auction sites is also growing rapidly. Third-party auction houses accounted for 15 percent of all consumer e-commerce spending in the first six months of 1999, or US\$1.5 billion (Oberndorf, 1999).

It could be argued that direct auction houses have adopted their bricks and mortar business models to incorporate advantages offered by e-commerce to enhance their existing businesses. Third-party auctions on the other hand have attracted many first time sellers, or 'would be entrepreneurs'. More than 41 million people shopped on eBay in 2003, listing a billion items and spending US\$24 billion (Alterio, 2004). As technology laggards continue to adopt the Internet, it is realistic to predict that even greater rates of spending growth will be realised. Pinker, Seidmann and Vakrat (2003) identified that research is needed to characterise the behaviour of participants in online auctions and to measure their 'response to actual market conditions and rules' (p. 1481). To this end, sales data collected by examining winning bids placed on goods offered for sale by an individual eBay user are presented later in this paper as an example of a possible pricing scenario. No claim is made that the data presented is typical, but a need for further research is indicated. Because eBay so dominates the third party auction landscape an overview of its development follows, before the pricing scenario example is presented.

### **The eBay phenomenon**

eBay has emerged as the premier third-party auction house with listings from every country in the world, and an increasing number of country specific sites (such as eBay USA, eBay Canada, eBay UK, eBay Australia). From humble beginnings, eBay is the undisputed third-party auction leader which has spawned the growth, replication and entrepreneurial activity that is now associated with online auctions.

eBay was founded by Pierre Omidyar in 1995. In the book, *The Perfect Store: Inside eBay* (Cohen, 2002), it is alleged Omidyar developed eBay as a result of a dinner table conversation. His fiancée Pam Wesley a PEZ-dispenser collector sought fellow collectors in California, and Auction Web was born. Having interviewed Omidyar,

Cohen believes that the real reason for the development was that the timing was right. By the mid 1990s, the popularity of newsgroups was being overtaken by the emergence of the World Wide Web. Omidyar, like every other programmer of the time, was constantly looking for new uses for the Internet, and the idea for an auction came from a variety of sources, not just the PEZ dinner conversation.

What is significant, is that Omidyar at the time was a potential entrepreneur, not a wannabe.. 'Auction Web' the original auction site was hosted on eBay.com, Omidyar's personal web page. In *The Perfect Store: Inside eBay*, it is claimed that Auction web was only started as a hobby, so costs were kept to a minimum. The page was hosted for US\$30 a month, and also included other pages: one for a biotechnology company Omidyar's fiancée worked for at the time, and a tongue-in-cheek 'tribute' to the Ebola virus and Ebola outbreaks.

Omidyar kept Auction web free throughout 1995, but was forced to introduce fees in 1996 as his Internet Service Provider started charging US\$250 a month for hosting. The site was getting so much traffic it was slowing down the ISPs system. Omidyar introduced fees to pay for the web hosting, not knowing if people would be prepared to pay. In time, the other home pages were removed and Auction Web became eBay. Based largely on user trust, and later public peer review, Auction Web broke even after a month and has been the industry standard ever since. eBay is the fastest growing company of all time. There has been controversy over the sale of various items on eBay from time to time. People have tried to auction organs (kidney), towns and even brides. Many cheap imitations of goods are also sold, and are difficult to monitor, making fraud an issue.

The Wikipedia (Wikipedia.com) entry for eBay states that revenue is generated from sellers, who pay a 1.25% to 5.25% premium on the final bid price of each item, a fee based on the starting price and from advertising. It does not handle the goods, nor does it transact the buyer-seller payment, except through its subsidiary PayPal. Instead, much like newspaper 'wanted' advertisements, sellers rely on the buyer's good faith to make payment, and buyers rely on the seller's good faith to actually deliver the goods intact. To encourage fidelity, eBay maintains, rates, and publicly displays the post-transaction feedback from all users, whether they buy or sell. This way, the buyer is encouraged to examine the seller's feedback profile before bidding to rate the trustworthiness. Sellers with high ratings generally have more bids and may also receive higher bids.

There are now hundreds of auction sites, world wide. Some are successful but many have failed or have been taken over. eBay is so dominant in the market that it is difficult for other players to compete for buyers and sellers and more importantly for user confidence and trust. After only a decade, online auctions have become a fact of life for many people, and opportunities for entrepreneurs abound.

### **A pricing scenario**

As there are millions of listings at any one time on eBay, many factors would influence the outcome of each auction. In order to explore the possible effect of online auctions on price, one seller was selected and the final value of goods sold was collated for a 60 day period. The seller was known to the researcher and all cost and final monetary values were made freely available. A descriptive profile of the seller is

presented in table 1. New books were chosen as a product category to avoid the effect of one-off sales, as the same title could be relisted and sold repeatedly. Many other product categories, such as CD's, DVD's, cameras, and computers could equally have been used.

---

Table 1 about here

---

The average auction price achieved for 15 different titles is shown in table 2. Each title was sold between two and five times over the 60 day period. 75% of titles consistently sold for more than the recommended retail price. Book cost price is achieved by deducting 40% from the retail price, therefore every title would have made at least a modest profit. The 63 books returned 132% of the total recommended retail price.

### **Internet auction buyers**

Internet auctions allow buyers to participate in auctions 24 hours a day, providing instant gratification and the ability to interact with the seller (Hoffman and Novak, 1996). Many early shoppers visited auction sites looking for collectables, but increasingly, it is for mainstream items such as motor vehicles or even houses (Alterio, 2004). The thrill of the auction is a historic phenomenon. People have a perception they will be able to purchase items for the lowest possible price. Although bargains are certainly attainable, Alterio concludes that, "one of the thrills for eBay users is the bidding process". Comments from users interviewed by Alterio include, "I think you get emotionally wrapped up in it"; "my mother couldn't be happier"; "imagine shopping for groceries and having the cashier congratulate you on 'winning' your bag full of milk, apples and toilet paper"; and, "Jennifer can be competitive". The motivation for Internet auction buyers is obviously complex and each case is different. Buyers range from passionate collectors, to pragmatic bargain hunters, to users who see online auctions as a "participation sport".

### **Internet auction sellers**

Retailers, manufacturers and liquidators are increasingly using online auctions to sell returned, demonstration or refurbished stock. Dell regularly sells demonstration and repackaged computers, monitors and other goods in Australia on Greysonline.com. At the time of writing, eBay Australia had listed 450 computers, 2,596 cameras and accessories, 350 mobile phones and 4,638 books.

Halstead and Becherer (2003) cited the following reasons for sellers using Internet auctions:

- To unload discontinued, returned, damaged or overstocked goods (Collett, 2000; Reda, 2000)
- To test prices in order to see what the market will bear (Collett, 2000)
- To acquire new customers (Machlis, 1998) and keep new customer acquisition costs low (Warner, 2000)

- To sell quality, designer goods at a discount, appealing to the ‘price-only’ shoppers (Warner, 2000).
- To generate excitement about an online site and to involve customers in an interactive sense (Oberndorf, 1999).
- To connect buyers in real time (Reda, 2000)
- To complement traditional brick and mortar businesses and enhance retail store values (Colombo, 2000)
- To give seasonal products a broader year-round appeal (Lewis, 2000)

Halstead and Becherer (2003) found that online auction sellers clearly vary in terms of company size and scope. Less than 15 percent of the smallest online auction sellers (<US\$25,000 p.a.) reported selling on Internet sites other than eBay whereas in direct contrast only 15 percent of the largest sellers (> US\$250,000) were found to use eBay exclusively. Freedman (2000) found that in addition to large corporate sellers, auction participants included *microbusinesses*, a class of small enterprises or entrepreneurs who have “successfully manoeuvred the online marketplace”. These microbusinesses could be a single individual operating out of a home using third-party auctions or their own auctions. It was further suggested by Freedman that these microbusinesses could pose a real threat to small online businesses because of low cost structures and rapid response times.

Halstead and Becherer (2003) propose an Internet “hierarchy of distribution commitment”, for small businesses with auction sales as a first step, followed by catalogue or wholesale distribution (or both), then the addition of other Internet sites. This hierarchy may be plausible for *would-be* or *established entrepreneurs*, but would it be plausible for *potential* entrepreneurs who may be happy operating microbusinesses? This *hierarchy of distribution commitment* hypothesis should be the subject of future research. What is clear is that online auction sites are being used actively by entrepreneurs, and they are the exclusive realm of thousands of *potential entrepreneurs*.

### **Complimentary, support and peripheral services**

In a very short period of time, online auctions have spawned a host of support and peripheral entrepreneurial activity. They range from copy-cat online auction hosts to software, financial services, forums, newsletters, books and recently a return to ‘bricks and mortar’ stores.

### **Third party auction sites**

The main auction sites are eBay, Amazon, CNet, MSN Auctions and Yahoo. There are hundreds (perhaps thousands) of small niche or general interest auction sites. Stuff.com.au is a general purpose auction site that still has a faithful Australian following. Auction sites for collectors are common, with names like stampsatauction.com, playle.com, bearauction.com. It is not easy to gauge how successful these sites are. Ftpplanet.com/ lists about 75 different auction sites. eBay dominates the online auction market, to the extent that the viability of many small auction sites would surely be questionable. Some failed sites are for sale, or in the case of uAuction.com just the domain name is for sale for US\$50,000.

eBay is also actively acquiring competitors. On June 22, 2004, eBay acquired Baazee.com an Indian auction site for US\$50 million; in September 2004, the Korean Internet Auction Company (IAC) was acquired for about US\$300 million.

Some firms or government organisations develop their own auction sites. In Australia, an example is [governmentauctions.com.au](http://governmentauctions.com.au). The site is prominent in Australian search listings, but most states are not represented, and in essence it was a gateway to private auction companies that were selling government motor vehicles. Whether companies should conduct their own auctions or not is unclear. There would be a potential benefit in terms of brand identification, but it could also blur the line between fixed price retail and an open cry auction. Although Dell is a prominent seller on [greysonline.com.au](http://greysonline.com.au) there is obvious separation between Dell and Greys, which may suit the Dell's marketing strategy.

### **Financial services**

When eBay was started in 1995, it was not clear that commerce would ever be trusted on the Internet. Cohen (2004) cites a 1995 study by the Pew Research Centre that reported that only eight percent of Americans felt comfortable using a credit card online. Besides establishing trust and confidence in the auction process, there was an obvious need for secure payment services for domestic, national and international transactions. Early payments to Auction Web involved the posting of cash or cheques via the postal service, and it is arguable that the rapid growth of online auctions may not have been possible without the emergence of alternative secure online payment methods. Most corporate sellers have secure credit card payment facilities, but it is the 'microbusinesses', both buyers and sellers, that have benefited by the availability of flexible, cheap online payment options.

Paypal, the best known international payment service was founded in December 1998. It now has 27 million members, largely from eBay which acquired the company in October 2002. Paypal has members from 38 countries, with support for five currencies, and a current turnover of US\$2.5 billion a quarter. Alternative payment methods are also available. In Australia, there is [paymate.com.au](http://paymate.com.au) which can be used to settle Australian auctions. While good for Australian auctions, Paymate cannot be used to settle international auctions, so its use is limited. The other main method of payment is Bidpay by Western Union. Bidpay allows for direct deposit to bank accounts in the United States, or international money orders can be delivered in the rest of the world.

A variety of alternative payment methods have also been developed, including eCash, eZidbit, and smart cards. There have been many attempts by entrepreneurs to develop e-commerce payment solutions, but most have not found ready acceptance. As eBay dominates the online auction market, Paypal dominates online payment. Some sellers place restrictions on purchases from international buyers, but it is likely that their reasons would be based on logistics or parochial attitudes rather than a lack of payment options.

## **Software solutions**

Fully integrated auction software is available for between US\$100 and US\$1,000. XAuction.com provides a full featured auction suite for US\$500. An inspection of several Xauction customer sites provides evidence that the software worked well, but the sites had limited listings and appear to experience limited traffic. Calcruising.com is a good example of a unique motor vehicle site that is well presented with listings, but limited interest as expressed by live bids. Search of Google for auction software solutions returns a wide variety of products from sniper programs to total shop front and multiple auction listing engines. Examples include shopping cart solutions, integrated auction/web page design, auction trackers, classified advertising and auction software. Buyers often make last minute bids, a practice called 'sniping'. Sniping programs are also popular; they are designed to bid on a user's behalf near the end of an auction, usually at five second intervals. Sniping programs include Bidnapper, Auction Sniper, Action Sentry and Just Snipe. Just Snipe does not require downloading and it allows five free snipes a week, or unlimited snipes and extra features such as tracking for US\$5 a month.

As the use of online auctions continues to grow, the communication performance of sites will affect all parties involved in them (McAdam, 2001). Current online auctions are slow moving. To compete with face-to-face auctions some auction sites are using Webcast techniques but these are still unicast (one sender to one receiver) and are restricted by bandwidth. Some researchers are advocating research into multicast-based auctions with an expectation of improved performance (Liu, Wang and Fei, 2003).

## **Books**

There are many books and newsletters devoted to online auctions. Newsletters such as [www.auction-sellers-resource.com](http://www.auction-sellers-resource.com) and [www.auctionservices.com](http://www.auctionservices.com) are provided free, and the sites also offer items for sale: a range of books, software, and other auction products and services. A search of Amazon.com revealed 227 matches for books on eBay, and 80 matches for online auctions. At the time of writing the five top selling titles listed on Amazon.com were -

- 1) eBay for Dummies, Fourth Edition by Marsha Collier.
- 2) eBay Secrets : How to create Internet auction listings that make 30% more money while selling every item you list [DOWNLOAD: PDF]  
by Steven Ellis White, Bryon Krug – \* note that this title was only available to download as a PDF file.
- 3) How to Sell Anything on eBay . . . and Make a Fortune! by Dennis Prince
- 4) Starting an eBay Business for Dummies by Marsha Collier
- 5) The Official eBay Bible by Jim Griffith

## **Bricks, mortar and virtual service opportunities**

Despite the large number of people who use online auctions, many do not own a computer, are not connected to the Internet, do not want to learn or do not trust e-commerce. Many businesses are emerging to fill this gap. Reasondropshop.com is a store in Sacramento U.S.A. that lists items on eBay on behalf of sellers, and there are stores opening throughout the world. Some like *Reasondropshop*, or German based *Dropshop* are physical stores while others are virtual. Fraud is relatively common online, so trust is very important to users of auction sites. As stores develop healthy peer online reviews, it is expected that this would contribute considerably to the level of trust and business growth.

Many new ways to use online auctions are and will continue to evolve. The Chicago Department of Cultural Affairs presented “The Great Chicago Fire Sale”, the first charitable eBay auction organized by a municipality, in December 2004. Auction items included Chicago related objects, one-of-a-kind experiences and special services. Some donated items included an original 1960s Playboy Bunny costume; a dinner party prepared by Art Smith, personal chef to Oprah Winfrey; a 2 night stay in the Presidential Suite at the Sofitel Chicago Water Tower; a cow from the acclaimed “Cows On Parade” public art exhibition; a opportunity to dye the Chicago River green for St. Patrick’s Day; and a painted sewer manhole cover. All of the items along with detailed descriptions were available on [www.thegreatchicagofiresale.org](http://www.thegreatchicagofiresale.org) (see figure 1). An inspection of the Chicago fire sale in progress indicated that it was a huge success. At the time of viewing (13 December 2004) 234 items were listed, and most had bids. The highest bid at the time was \$7,000 for a wedding for up to 100 guests.

## **Discussion and implications**

The online auction marketplace presents a challenging and exciting environment for existing and potential entrepreneurs. The availability of new technology and the increased accessibility of Internet connectivity are shaping a new economy with different methods of distribution, marketing, selling and arranging work. Attributes of this new economy include collapsing boundaries between firms, suppliers, customers and competitors (Hartman et al., 2000; Morino, 1999). Any new form of commercial activity tends to attract entrepreneurs, and online auctions are no exception. “What sets netpreneurs apart is not that they are different from other entrepreneurs, but that they are operating in a universe of transforming change. As pioneers of the new networked society, they are both defining and learning new ways of doing business” (Morino, 1999:).

What appears to be different about Internet entrepreneurs is their need for constant innovation and experimentation which may not be present in other groups of entrepreneurs. This paper also questions the notion that auction sites are only the realm of price sensitive bargain hunters. The nature and accessibility of online auctions is particularly attractive to potential entrepreneurs, partly because of the ease of entry and low cost of participation. Further research is needed to explore and determine differences between cyberentrepreneurs and other entrepreneurs as there is currently a gap in entrepreneurship theory and practice.

## **Macroeconomic Aspects of Small Business Development in Poland**

### **Abstract**

With the fall of Communism in the former Soviet Union, a number of countries have been faced with the prospect of transforming from a command economy to a market-oriented one. This paper is a preliminary investigation of entrepreneurial activity and economic development in the Polish economy. Entrepreneurial activity is believed to be the fundamental force in the transformation of economies in former communist countries towards free markets.

The transformation in Poland has been facilitated by the privatization of state owned enterprises and the development of the private business sector. The foreign direct investment (FDI) in Poland, which have played important role in the privatization and restructuring of the Polish economy has been discussed and macroeconomic indicators of economic performance within Poland, the European Union Countries (euro-zone) and Central and Eastern Europe have been analyzed.

Macroeconomic aspects of small business development in Poland examined in the paper include: number and size of business firms in private sector in Poland, share of the private sector, particularly small and medium size firms in gross domestic product (GDP), their share in total output of the economic sectors, national employment, and foreign trade.

The study shows that small business development plays a very important role in the process of transition from a command to a market oriented economy in Poland. Growth of free enterprise in Poland constitutes an important factor in economic development, stimulating output, creating employment and expansion in the foreign trade in the Polish economy.

## **Introduction**

This paper deals with the transformation from a centrally planned economy to market oriented economy in Poland and examines macroeconomic aspects of small business development in the Polish economy.

Development of the private business sector in Poland constitutes an important component of economic development and is an essential factor in creating employment in the Polish economy. In order to analyze small business development in Poland, it is important to understand the following issues: transformation of a centrally planned economy to a market oriented economy, macroeconomic changes related to economic growth, replacement of the command mechanism with market mechanism and privatization of the Polish economy ([www.parp.gov.pl/publikzam.php](http://www.parp.gov.pl/publikzam.php)).

This study assumes that the number of registered small business firms in the economy is a key measure of entrepreneurial activity and that the growth in the number of private firms indicates growth in entrepreneurial activity (Adrangi, Allender, and Anderson 2003). Entrepreneurial activity constitutes an important ingredient in the process of economic development and transformation from central planning to market oriented economies. This transformation has been facilitated by the privatization of small and medium state-owned companies and a liberal law on establishing new firms that has allowed for the development of the private business sector.

Part one focuses on assessing the transition period and includes: the foreign direct investment (FDI) in Poland, which have facilitated the privatization and restructuring of the Polish economy, macroeconomic indicators in the Polish economy with the focus on high unemployment rate, and macroeconomic indicators within the European Union Countries (euro-zone) and the Central and Eastern Europe.

Part two concentrates on macroeconomic aspects of small business development in Poland and examines: number and size of business firms in private sector in Poland, share of the private sector, particularly small and medium size firms in gross domestic product (GDP), their share in total output of the economic sectors, national employment, and foreign trade. This part compares the dynamic growth of GDP with the growing number of firms in the private sector indicating a link between growth in the number of private business firms in the Polish economy and the level of economic growth measured in terms of real GDP.

## **ASSESSING TRANSITION**

### **Transformation from a command into a market oriented economy**

State-owned enterprises were the dominant players in the socialist economies during the command era. The main economic problems related to the command era included inefficiencies in production methods, stagnation of production rates, poor quality of the

items produced, high pollution rates and lack of technological innovation. Transition is the process of replacing of one economic system with another. The command system in Central and Eastern Europe dates from the end of World War II. In the 1980s, the command economies of Eastern Europe collapsed, culminating in the 1989 fall of the Berlin Wall and Germany re-unification; in 1991 Cold War was over (Case & Fair, 2004). Changes in Poland's economy began in 1980 with the Solidarity movement, followed by the implementation of martial law in 1981. Privatization took place as state owned firms were converted to private ownership. Poland was the first of the former socialist countries to begin recording positive economic growth. Foreign investment was flowing into the country and thousands of entrepreneurs started new businesses. Capital flows typically take the form of foreign aid, portfolio investment and foreign direct investment (FDI). Foreign direct investment deserves special attention as a major component of capital flows in Poland.

The past decade has been Poland's most successful in 300 years. Poland is strategically integrated with NATO and, on May 1, 2004, became a member of the European Union together with the Czech Republic and Hungary ([www.eurunion.org](http://www.eurunion.org)). The membership of Poland in the European Union has been important for political as well as economic reasons. The government's determination to enter the EU has shaped most aspects of its economic policy and new legislation.

Poland is one of the largest economies in Central and Eastern Europe with a mostly Roman-Catholic population of 38.6 million, a relatively high GDP per capita (US\$9,410) that is comparable to that of the Czech Republic (US\$12,900) and Hungary (US\$11,200). The top priorities in Polish economy are the competitiveness of exports, the problem of high unemployment and soaring budget deficit, the development of financial markets, monetary and fiscal institutions.

There are a variety of indicators assessing transition outcomes in the Polish economy. Analysis will be limited to the main macroeconomic indicators with a focus on GDP, unemployment, and inflation.

### **The Importance of foreign direct investment (FDI) in the Polish Economy**

Foreign direct investment (FDI) has increased in the past twenty years, to become the most common type of capital flow, needed for the stabilization and economic growth of the Polish economy in the transition period. Foreign capital is seen to facilitate the privatization and restructuring of the economy. The privatization process has required large supply of capital, very often not available for the domestic companies. Poland has identified the positive effects of FDI on the transformation process of the economy.

Governments, many of which have formal FDI promotion programs and provide substantial incentives for foreign companies, have officially encouraged FDI. The last decade in Poland has made it clear that foreign direct investment have created employment, increased productivity and exports and led to transfers of knowledge and technology to the host countries ([www.regeringen.se/sb/d/1284/a/29424](http://www.regeringen.se/sb/d/1284/a/29424)). The Figure 1

presents FDI in Poland between 1993 and 2002. The highest amount of FDI has flown to Poland between 1998 and 2001 and it amounted about 35 billions of US dollars.

X-----

Figure 1 ... about here  
Foreign Direct Investment in Poland (in billions US\$)

X-----

Analyses of percentage share of the foreign countries in total foreign direct investment in Poland (2002), indicates significant contribution of France (20%), the USA (15%) and Germany (14%). Other European countries such as: the Netherlands, Italy and the U.K. participated respectively 9%, 7%, and 5% in total FDI. Multinational companies accounted for 5% of the total FDI in Poland. The remaining countries: Sweden, South Korea, Russia, Belgium, Ireland, Denmark, Cyprus, Switzerland, Austria, Norway, Japan, Greece and Portugal contributed to the total FDI between 4% to 1% ([www.paneurasian.com/di.pdf](http://www.paneurasian.com/di.pdf)).

The Table 1 shows total capital flow for the selected front-running transition economies: Poland, the Czech Republic and Hungary. The size of FDI flowing to the transition economies was impressive. FDI in Poland between 1989 and 2001 accounted for 3.6% of GDP. FDI per capita in Poland was relatively low in comparison with the Czech Republic and Hungary because of high population number.

## **GDP per Capita and Economic Growth in Poland**

As the centrally planned economy began to collapse, state control of economic activity collapsed and decentralization of decision making occurred. GDP per capita and the economic growth are important indicators for judging transition. The most characteristic aspect of economies in transition has been the initial collapse of output and its slow recovery. During the early years of transition, the decline of economic activity in all transition economies was significant. The collapse of the Polish economy was modest and recovery relatively fast (Gregory & Stuart, 2004). Growing GDP per capita between 1990 - 2000, indicates an increase in the standard of living in Poland (Figure 2) and analysis of real GDP between 1995 -2001, also shows a dynamic increase in domestic output by 29.7% with a declining rate of economic growth from 6% to 1.3% (Table 2).

### **Unemployment Rate in Poland**

Unemployment was theoretically nonexistent during the command era and became an important problem during transition period. It is known that there was *hidden unemployment* during the command era. It was difficult to dismissed workers, whether productive or not. The job was guaranteed by the law. The central issue during the transition era has been the movement of labor from the inefficient state sector to the emerging private sector. As a result of this process, the unemployment rate increased significantly. Liquidation of state own firms, and the direct or indirect transformation from state owned firms to private ownership contributed to the high unemployment rate in Poland. Other factors influencing unemployment rate relate to the introduction of the market economy and modern technology; inefficient private enterprises go out of business and new technologies require more skilled labor and lead to structural unemployment in the industry sector in Poland. Between 1990 and 2004 the unemployment rate in Poland increased from 0.3% to 20% (Figure 3). Very high unemployment has been a serious problem in Poland. The transition economies have developed systems of unemployment compensation, however, inequality and poverty have become a great threat.

X-----  
Figure 3 ... about here  
Unemployment Rate in Poland 1990 – 2004  
X-----

### **Inflation rate in Poland**

During the command era, prices were set by the state. In the early period of transition prices were released from state control. In the early 1990s, prices increased sharply as a result of a market imbalance. Centrally planned economies have been characterized as *economies of shortages*. With the transition to a market economy, the prices of goods and services in short supply were pushed upward. Another important factor that fueled inflation during the early years of transition was the devaluation of currency that led to an increase in exports and financial inflows of loans, grants and direct foreign investments. Between 1989 and 1990, the consumer price index increased from 351.1% to 685.8%, causing the highest inflation rate during the transition period, called *hyperinflation* or *shortage inflation* (Figure 4). To stabilize the economy and decrease the inflation rate a radical strategy called *shock therapy* was introduced (Kolodko, 2003). It resulted in

further institutional changes and government decentralization, increased private ownership, reconstruction of the banking system and stock exchange development.

### **Comparison of macroeconomic indicators within the European Union Countries**

Comparison of macroeconomic indicators in Poland with the European Union (euro-zone) countries in 2002 (Table 3), shows that GDP in Polish economy is growing faster than in the EU countries (1.3% versus 0.9% average), while inflation rate remains below the EU inflation rate (1.9% versus 2.2% average). However, unemployment rate in Poland is much higher than average unemployment rate in the EU (18.1 versus 8.3) and the budget deficit as a percentage of GDP is much above the EU average (5.6% versus 2.2%).

Comparison of macroeconomic indicators (Table 4) shows that Poland has the highest unemployment rate (18.1%) among the Central and Eastern European Countries, the lowest economic growth rate (1.3%) and relatively low inflation rate (1.9% versus the record high 23.7% in Rumania and 15.1% in Russia).

## **MACROECONOMIC ASPECTS OF SMALL BUSINESS DEVELOPMENT**

### **Number and Size of the Small and Medium Business Firms in Poland**

During the early years of transition, many entrepreneurs started private businesses. This study assumes that the number of registered small business firms in the economy is a key measure of entrepreneurial activity. The growing number of private firms indicates growth in entrepreneurial activity. Entrepreneurial activity constitutes an important ingredient in the process of transforming Central and Eastern Europe from centrally planned to market oriented economies (Mueller & Goic, 2002). In early 90's Poland, DDR, the Soviet Union and the Czech Republic reached relatively high levels in private enterprise development. Transitioning economies, particularly Poland, show tremendous

dynamics in small business development. The numbers of small business firms registered in Poland during 1991 and 2004 increased from 1,200,000 to 4,736,000 (Table 5).

X-----

Table 5 ... about here  
Number of Firms in Private Sector in Poland; 1991 – 2004  
X-----

Poland is acknowledged as the leader in Eastern Europe in privatization and in the movement to a market oriented economy. Micro, small and medium size business firms (1-249 employee) constitute 99.8% of all the private firms in Poland (Table 6). The most common form of business firm in Poland is the micro firm (1-9 employee). Micro firms constitute 95% of all the firms in the private sector.

X-----

Table 6 ... about here  
Number and Size of Firms in Private Sector in Poland in % (1999-2002)  
X-----

### **Share of Private Sector and Small and Medium Business Firms in GDP**

Transitioning economies focus on the creation of markets through a process of privatization. Privatization is the replacement of state-owned property with private property and the transformation of ownership from government to private hands. The development of small business enterprises represents an important aspect of the transition process.

To assess the success of privatization efforts, the extent to which economic activity has been privatized must be examined and the share of private sector output in national output must be determined. In 1992 less than half of the output was derived from the private sector whereas in 2000, the share of the private sector in the total output increased to 70% in Poland, 80% in Hungary and 80% in the Czech Republic.

Micro, small and medium firms (1-249 employees) play a critical role in the national economy in Poland, generating about 48% of the Gross Domestic Product (Table 7). The micro firms (1-9 employee) accounts for about 30% of the national output, showing an increasing share in GDP between 1999 and 2002, while small (10-49 employee) and medium firms (50-245) demonstrate a decline in GDP during this period. This leads to the conclusion that the smallest firms, micro firms, show sustained growth in comparison with other categories of firms in Poland.

X-----

Table 7 ... about here  
Share of Private Sector in GDP in Poland (%): 1999-2002  
X-----

## Share of Small and Medium Firms in Total Output of the Economic Sectors

The percentage share of small and medium firms in total output of the economic sectors in Poland indicates that, they generate between 91,1% and 99,1% of total output in education, retail and repairs, real estate and other, as well as in health. They contribute respectively 87.9% and 83.0% to the total output in construction as well as in hotels & restaurants. The industry sector (mining, manufacturing, electricity, gas, water) as well as transport and communication are still dominated by public sector and small and medium firms generate respectively only 40.8% and 44.9% of the total industry output (Table 8).

X-----

Table 8... about here

Share of Small and Medium Firms (1-249) in Total Output of Economic Sectors in Poland 2001

X-----

## Economic Growth and the Growth of the Private Business Firms

Economic growth in the Polish economy seems to be a strong indicator of entrepreneurial activity. This is consistent with the Schumpeterian view that entrepreneurial activity and economic growth are closely linked (Mueller & Goic, 2002).

Dynamic growth in real GDP in Poland has been compared with the growth of the registered private business firms in Poland between 1995 and 2005 (Figure 5). The results indicate a link between growth in the number of private business firms in the Polish economy and the level of economic growth measured in terms of real GDP.

X-----

Figure 5... about here

Economic Growth vs. Growth of Registered Business Firms

X-----

## Share of Private Sector and Small and Medium Firms in Employment

Dynamic development of the private sector in the Polish economy constitutes the most important factor generating employment in the economy. The private sector accounts for 72,5% of employment in Poland while the public sector constitutes 27.5% ([www.stat.gov.pl](http://www.stat.gov.pl)). Micro, small and medium firms (1-249 employee) constitute the base of employment in the Polish economy, generating employment of about 62.16%. The structure of employment in the firms employing 1-249 units of labor in 2001 was as follows: micro firms employed 14.72%, small firms 20.85% and medium firms 26.58% of the national employment (Table 9).

X-----

Table 9 ... about here

Employment in Private Sector in Poland (%)

X-----

According to the government of Poland, it is necessary to encourage entrepreneurship and create the conditions for the acceleration of economic development and the improvement of job opportunities. In *Entrepreneurship-Development-Work* ([www.parp.gov.pl](http://www.parp.gov.pl)) the government presents its strategy to develop entrepreneurship which it sees as the basic source of both economic growth and the creation of new jobs. The package provides for actions to eliminate formal barriers to the establishment and running businesses and facilitate the growth of employment

### **Share of Small and Medium Firms in Foreign Trade.**

Centrally planned economies were isolated from the global markets and world competitive forces. The sudden transition of the late 1980's forced the transition economies to adapt to the global environment. The most dramatic example of such change is the development of the European Union. Joining the European Union has been an important goal for the transition economies of Central and Eastern Europe ([www.eur.union.org](http://www.eur.union.org)). During the command economy there was no mechanism for the inflow of foreign capital because of the lack of financial markets. There was absence of a convertible currency during the command era, leading to the dominance of barter arrangements functioning through state trading organizations.

Table 10 includes share of private firms in foreign trade between 1999 and 2001 and illustrates important role of small and medium firms in Polish export and import. In 2001, small and medium firms participated 44% in export and 59.4% in import. The large firms accounted for 56% in export and 40.6% in import. Increase in the value of export characterized foreign firms only. Export of Polish firms showed declining tendency.

### **Summary**

This paper discussed the transformation from a centrally planned economy to market oriented economy in Poland and examined macroeconomic aspects of small business development in the Polish economy.

The foreign direct investment (FDI) have played important role in facilitating the privatization and reconstruction process of the Polish economy during transition period. Analyzes of macroeconomic indicators identify the unemployment rate in Poland (18%) to be a critical issue in the Polish economy and to be one of the highest rate among the European Union Countries (euro-zone) and the Central and Eastern Europe.

**The research found that private business enterprise development plays an important role in the acceleration of economic growth.** Poland shows tremendous dynamics in small business development. The private sector continues to facilitate economic growth and employment in Polish economy, constituting about 70% of GDP and generating 72,5% of employment in the country.

The paper showed the increasing share of the private sector, particularly small and medium size firms in the Polish economy and has proved the key role of small and medium firms in macro economy of the country. The private sector now constitutes the basic source of GDP and the base of employment in Poland. Micro, small and medium business firms in Poland (1- 249 employee) constitute 99% of all the firms in private sector, accounting for about 48% of GDP and create about 62% of employment in the national economy.

The smallest business firms, micro firms (1- 9 employees), account for 95% of all the firms in private sector, 30% of GDP, and 14% of the employment in the private sector. Micro firms show an increasing share in GDP between 1999 and 2002, and sustained growth in comparison with other categories of firms.

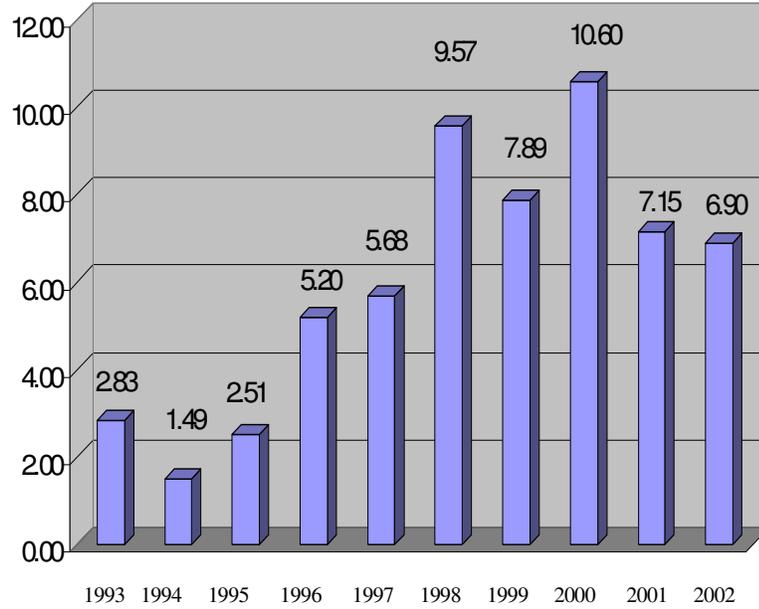

This paper showed the results of the globalization process and the strong involvement of small and medium firms in foreign trade. The membership of Poland in the European Union has been important factor in foreign trade development. In 2001, small and medium firms participated 44% in export and 59.4% in import while large firms accounted for 56% in export and 40.6% in import.

The study confirmed that small business development plays a very important role in the process of transition from command to market oriented economy in Poland. Growth of free enterprise in Poland constitutes an important factor in economic development, stimulating output, creating employment and expansion in the foreign trade in the Polish economy.

## **TITLE**

“CONSULTING AND ADVISING A NEW BUSINESS START-UP BY APPLYING LESSONS LEARNED FROM THE APPRENTICE REALITY SIMULATION”

## **EXTENDED ABSTRACT**

Reality television shows such as *The Apprentice* are extremely popular and challenge individuals and teams to compete against each other for the ultimate prize of working with Donald Trump. Using *The Apprentice* television show as a template for a classroom project, students were able to learn first hand how to develop a marketing plan and organize a promotion. How do simulations such as this provide a sufficient learning experience and can the students who participate in the simulation be successful when they are called upon to advise and consult a business in the real world?

## **THE APPRENTICE CLASSROOM SIMULATION**

To gain real life work experience is sometimes difficult for college students, especially if that work experience involves making a decision that has a direct impact on the individual sales force, the business, and the community. To give college students a real life experience, two car dealers offered a challenge to twenty college students. The first challenge was to see which team could generate the most BUZZ during a one-week promotion. The second challenge was to see which team could gather the most donated food for the local food pantry. The title of the simulation was the *Chadron Apprentice Challenge*.

The *Chadron Apprentice Challenge* has a competitive side. The challenges involve car dealerships in towns approximately 50 miles apart. To add a competitive flair the student teams competed against each other. Student teams were in complete control of the promotion, the sales staff and advertising. (Subject to final approval by the owner for legal reasons). These students used a combination of the courses they had taken in business including; advertising, management, marketing, accounting, and communications.

### **CHALLENGE ONE:**

Two teams of five-members each participated in local version of *The Apprentice Challenge* to see which team could generate the most BUZZ for a car dealership. The dealership has locations in two neighboring towns 45 miles apart. Each team was given a budget of \$2000 and the opportunity to work with a professional advertising agency. The teams individually generated a marketing and advertising plan for a one-week period. (The plan was approved in advance by the dealership to meet legal requirements).

The teams used a combination of radio; print, flyers, and a car give away promotion. One team took pictures of young children on Santa's knee and gave them away. Both team had to stay under their initial budget.

The two teams were given only one week to plan the advertisements, get the copy approved, cut radio ads and gain the commitment of the sales staff. Once the promotion started the teams worked directly with the sales staff of both dealership locations. (Typically this was a slow time of year for the dealerships and employee moral was a bit low since the majority of the income for the sales staff is generated from commissions). The students were surprised just how attentively the sales staff listened to them and how eager the staff was to try something new.

After a one-week promotion the results were totaled and the students met with the owner to see which team won. To give this challenge the feel of a real life experience and to capitalize on the success of a popular television series we had the students meet in a formal boardroom to hear the results and to see who would be fired. The owner was so impressed that neither team was fired; he gave each member of the winning team a fifty-dollar bill. This was really unexpected by the team and very appreciated since it was Christmas. He also invited the teams to manage a complete month long advertising campaign in the spring.

The results of the promotion were fantastic. The sales were more than double the previous period in both locations. The sales staff was excited and motivated to try new things. John Miskimins owner of Miskimins motors stated, " I did not believe that our sales force would

actually listen to the young college students since none of them had ever sold cars, but I was wrong”. “Not only did the students get a first hand experience on how a business works, but our employees got re-energized and learned some new ideas from the students”. “This is a great “Win-Win” project and I can’t wait to do it again”.

### **CHALLENGE TWO:**

The second *Apprentice Challenge* was similar in design as the first project. In the second challenge two student teams developed advertising and promotion campaigns to see which team could bring in the most food for the two local food pantries. The car dealer gave the students a budget of \$1,000 for each team. The teams offered a variety of promotions to generate donations. One team offered an oil change to all customers who brought in a new toy and a discount on service to all customers who brought in food. (This promotion was part of the \$1,000 budget) To additionally help the promotion team took pictures of young kids sitting on Santa’s knee in exchange for a food donation.

Jamie Eisenbarth owner of Eisenbarth motors stated; “The challenge was really exciting for the us to see how the new generation of college students are using what they learn in the classroom and how they apply it to a real world experience”. “This was an unusual project since we were not directly selling anything and it is hard to get people to come into a store to give a donation, but these students really did a good job”.

At the conclusion of the food pantry drive the two teams had managed to accumulate enough food to go all the way around a basketball court “five” times. Not only did this project help the local food pantries restock their supply but it also gave several families food for the holidays, some young kids some new toys and there was a much joyous Christmas for many.

**RESULTS:** The *Apprentice Challenge* was designed to be a positive learning experience. Both dealerships received a lot of foot traffic associated with the promotions. The top teams were treated to a cash award or steak dinner by the dealerships. For the hard work by the teams the dealerships received a lot of good press and set record for sales in both locations, which the owners believe, had a direct affect on the promotion done by the two teams. The student teams received the chance to work with an advertising agency, to work as a competitive team setting, to develop a project and see the results. Who was the true winner? The community food pantry was restocked and several families had a much joyous Christmas.

## **APPLYING THE LESSONS LEARNED**

A new business heard about *The Apprentice Challenge* and asked the team to develop a marketing plan and theme for a new restaurant and bar they planned to open. The owners had no prior experience in running a business and needed a substantial amount of assistance. They also wanted to make sure that their investment

At the initial meeting the owners they were not sure what theme the new business should have. Should it be a bar that served good food or a restaurant that served alcohol with a bar in it? Another concern of the owners, should the new business have a smoking or non-smoking atmosphere. A group ten students, from the original apprentice groups, took on the challenge and met with the owners who gave the team an overview of what they “wanted” to do and asked the team to see if their plan was feasible within the community.

The ten students were divided into two five-member teams. One team did an analysis of a new bar serving good food while the other looked at a restaurant that served alcohol. The first step for both groups was to complete a SWOT analysis. In the SWOT analysis each group analyzed all competing businesses and a summary was completed. The results revealed that each business scenario had positive and negative aspects.

Step two was to develop a survey to help determine what the community wanted. Since there were positive and negative aspects with both scenarios the goal was to see which business type would be the best for the owners and the community. The teams worked

together to develop a survey instrument that would give results that both teams could use. By using one survey form saved time and made the results easier to compare.

Just over three hundred community people were surveyed. The community survey included a range in age from 18 to over 50. The teams then analyzed the data. Initially the owners had thought that college kids spent all of their non-school time at the local bar. The results gave a slightly different result. The legal drinking age is twenty-one and the majority of the traditional college community not legally able to drink alcohol until they are in their junior or senior year.

The survey revealed that these young students wanted to go out for an evening of fun and not be restricted entry to the bar because of their age. The results indicated that 83% wanted to have a restaurant that served good food at a reasonable price and one that also had a small bar similar to Outback, TGI Fridays, Applebee's and others.

The majority 77% also wanted a non-smoking restaurant. Other results of the survey gave the owners an indication of the dollar amount customers would be willing to spend for an evening out. Using this information the two teams recommended to the owners that the new business be a "Fun" non-smoking restaurant that served good food at a reasonable price. They also recommended that the theme have a sports bar atmosphere with several televisions and tables as well as a bar.

With a single theme identified and armed with the survey data and with additional information provided by the owners on operating expenses the combined group developed a break-even analysis and business plan for the new restaurant.

The Apprentice Challenge puts a new twist on the traditional service-learning concept. Students still learn by doing, but the Apprentice Challenge adds the competitive nature of a real world experience and challenges students to compete, not just participate. The challenge also allows some flexibility, each project and is individually focused on a particular theme and students get involved with a local business.

**AN EXAMINATION OF MANAGERS' ENTREPRENEURIAL ACTIONS  
AND JOB SATISFACTION**

**ABSTRACT**

Through the development and extension of theories and scholars' subsequent empirical analyses of significant, theoretically grounded research questions, the knowledge about corporate entrepreneurship (CE) and its successful use continues to advance. Moreover, the literature suggests important relationships between the corporate environment, managers' entrepreneurial behavior and successful implementation of corporate entrepreneurship actions. In an attempt to test some of those relationships, we describe an empirical study of 523 managers that examines the relationships among the antecedents to managers' entrepreneurial behavior, a decision to implement entrepreneurial actions, and resulting job satisfaction and reinforcement practices.

## INTRODUCTION

Increasingly, organizations are committing to the position that entrepreneurial actions are essential if they are to first survive and then achieve competitive success in a world that is being driven by accelerating change (Barringer & Bluedorn, 1999; Lyon, Lumpkin & Dess, 2000; Ireland et al., 2001). Entrepreneurial actions do not occur in a vacuum; rather, they take place within the context of the organization's full array of actions (Dess, Lumpkin, & Covin, 1997). Establishing an internal environment in large, established organizations that elicits and nurtures entrepreneurial actions is challenging and requires appropriate decisions (Sathe, 1985). However, as we demonstrate in this study, entrepreneurial actions are a product of organizational antecedents. Furthermore, we argue that managers' entrepreneurial actions can be a source of competitive advantage for a firm over its rivals (Floyd & Wooldridge, 1994).

### Role of Managers in Corporate Entrepreneurship

Managers at all organizational levels have critical strategic roles to fulfill for the organization to be successful (Floyd & Lane, 2000; Ireland, Hitt & Vaidyanath, 2002). According to Floyd and Lane (2000), top-, middle-, and first-level managers have distinct responsibilities with respect to each subprocess. Top-level managers have *ratifying*, *recognizing*, and *directing* roles corresponding to the competence definition, modification, and deployment subprocesses, respectively. According to Floyd and Lane (2000), middle-level managers have *championing* roles corresponding to the competence definition subprocess, *synthesizing* and *facilitating* roles corresponding to the competence modification subprocess, and *implementing* roles corresponding to the competence deployment subprocess. In examining the role of first-level managers, they are often the catalysts behind autonomous entrepreneurial initiatives. In Floyd and Lane's (2000) model, first-level managers have *experimenting* roles corresponding to the competence definition subprocess, *adjusting* roles corresponding to the competence modification subprocess, and *conforming* roles corresponding to the competence deployment subprocess.

### Organizational Antecedents

Research has examined the organizational antecedents that affect (either by promoting or impeding) the breadth and depth of entrepreneurial actions that are taken within the firm at a point in time to pursue CE (Zahra, 1991; Zahra & Covin, 1995; Zahra, Nielsen & Bogner, 1999). The research literature has been developing our understanding of organizational antecedents of entrepreneurial actions (Kuratko, Montagno, & Hornsby, 1990; Hornsby, Kuratko, & Montagno, 1999; Ireland, et al 2003). An integrated review and analysis of the literature demonstrates a grouping of five major categories or dimensions that are considered antecedents to entrepreneurial actions. These dimensions are: (1) *the appropriate use of rewards* to elicit and then support entrepreneurial actions; (2) *managerial support*, which indicates the willingness of managers, especially top-level executives, to facilitate and promote entrepreneurial actions; (3) *available resources*, including the time required to continuously engage in entrepreneurial actions; (4) *a supportive organizational culture*, which is a culture that is organic rather than mechanistic in nature; and (5) *work discretion (autonomy and risk taking)*, the ability or willingness on the part of managers, based upon their job descriptions, to take risks in the pursuit of innovation and to tolerate and learn from failures.

## **Job Satisfaction and Entrepreneurial Actions**

An individual's job satisfaction could have a mediating effect on the ability of a CE environment to spur entrepreneurial actions or performance. While the relationship between job satisfaction and performance has been a persistent "chicken and egg" question, recent research suggests that job satisfaction and performance are moderately related and mutually influence each other (Judge, Thoresen, Bono & Patton, 2001). Several recent studies examined the viability of the job satisfaction-performance relationship. These studies support Harter, Schmidt and Hays' (2002) contention that the relationship is more complex and that the analysis suffers from poor measures of both constructs. Furthermore, the research suggests that many variables may mediate and or moderate the relationship.

### **Purpose of the Study**

The purpose of this study is to investigate the relationship between the organizational antecedents that create a corporate entrepreneurial environment, as identified in Hornsby et al. (1999; 2002; and Ireland, et al 2003), and the entrepreneurial actions taken by managers. Also of interest in this study is the relationship between the existence of a corporate entrepreneurial environment and a manager's perceptions of job satisfaction. Specifically, the following hypotheses are offered:

**H1a, b, c, d, e:** The perceptions of a corporate entrepreneurial environment will be positively related to job satisfaction.

**H1a:** Management support will be positively related to job satisfaction.

**H1b:** Work discretion will be positively related to job satisfaction.

**H1c:** Rewards/reinforcement will be positively related to job satisfaction.

**H1d:** Time availability will be positively related to job satisfaction.

**H1e:** Organizational boundaries will be positively related to job satisfaction.

**H2a, b, c:** Job satisfaction will be positively related to entrepreneurial actions.

**H2a:** Job satisfaction will be positively related to the number of new ideas suggested.

**H2b:** Job satisfaction will be positively related to the number of ideas implemented.

**H2c:** Job satisfaction will be positively related to the number of unofficial improvements implemented.

**H3:** Job satisfaction will mediate the relationships between perceptions of a corporate entrepreneurial environment and entrepreneurial actions.

The model we will test and the hypotheses stated above are shown in Figure 1.

## **METHOD**

### **Sample**

The sample for this study was taken from approximately 670 managers who participated in continuing education and training programs for managers conducted by a large Midwestern

university. Participation in the survey was voluntary and approximately 80% of those eligible (530 individuals) chose to do so. Seven surveys were incomplete and were discarded, leaving a usable sample of 523. The average age of the respondents was 39.6 years, 75% were male, average organizational tenure was 12.2 years, and the average time in their current positions was 4.5 years. 30% described themselves as first level managers; 45%, mid-level managers; and 13%, senior-level managers. (12% declined to respond to this item)

## Measures

The Corporate Entrepreneurship Assessment Instrument (CEAI) (Hornsby, Kuratko, & Zahra, 2002)) was used to measure the organizational factors that foster corporate entrepreneurial activity within a company. Top management support for corporate entrepreneurship was measured by 19 items ( $\alpha = .90$ ), work discretion was measured by 10 items ( $\alpha = .87$ ), rewards/reinforcement was measured by 6 items ( $\alpha = .73$ ), time availability was measured by 6 items ( $\alpha = .77$ ), and organizational boundaries was measured by 7 items ( $\alpha = .63$ ). For each of these five scales, the participants responded to a 5-point Likert scale with responses ranging from “strongly disagree” to “strongly agree.” Job satisfaction was measured by the Minnesota Job Satisfaction Questionnaire (Weiss, Dawis, England & Lofquist, 1967) ( $\alpha = .88$ ). A 5- point Likert scale was used with the responses ranging from “very dissatisfied” to “very satisfied.” Entrepreneurial actions were measured by items developed by the authors. Each action was measured by a single item in which the respondents were asked (1) the number of new ideas suggested, (2) the number of new ideas implemented, and (3) the number of improvements implemented without official organizational approval. In each case the participants were asked to respond with number of these actions that had occurred over the past six months.

## RESULTS

### Measurement model

In order to test our hypothesized model, we formed manifest indicators as described by Bishop, Scott, Goldsby, and Cropanzano (2005) and subjected them to a confirmatory factor analysis (CFA). We formed 4 manifest indicators from the management support items, 3 from the work discretion items, 2 each from the rewards/reinforcement, time availability, and organizational boundaries items, and 4 from the job satisfaction items. Using a covariance matrix derived from these indicators we estimated a measurement model. The results indicate that the model fit the data well:  $\chi^2_{(104)} = 210.57$ , root mean square error of approximation (RMSEA) = .044, non-normed fit index (NNFI) = .99 and comparative fit index (CFI) = .99. The model shown in Figure 2 shows the measurement and structural portions of the model.

-----  
Insert Figure 2 about here  
-----

### Structural model

We tested our hypotheses by estimating the model shown in Figure 2. Again, the model fit the data well:  $\chi^2_{(152)} = 280.78$ , root mean square error of approximation (RMSEA) = .040, non-normed fit index (NNFI) = .99, and comparative fit index (CFI) = .99. Since  $\gamma_{12}$  and  $\gamma_{13}$  were

significant, hypotheses 1b and 1c, respectively, were supported, while hypotheses 1a, 1d, and 1e were not supported because  $\gamma_{11}$ ,  $\gamma_{14}$ , and  $\gamma_{15}$  were not significant. See Figure 3. Hypotheses 2a, 2b, and 2c were supported since  $\beta_{21}$ ,  $\beta_{31}$ , and  $\beta_{41}$  were all significant. Hypothesis 3 received partial support because the indirect effects of work discretion on the number of new ideas ( $\gamma_{12}\beta_{21} = .039 \pm .035$ ), the number of ideas implemented ( $\gamma_{12}\beta_{31} = .056 \pm .035$ ), and the number of unofficial improvements ( $\gamma_{12}\beta_{41} = .056 \pm .035$ ) were significant as were the indirect effects of rewards/reinforcement on the number of new ideas ( $\gamma_{13}\beta_{21} = .056 \pm .051$ ), the number of ideas implemented ( $\gamma_{13}\beta_{31} = .080 \pm .052$ ), and the number of unofficial improvements ( $\gamma_{13}\beta_{41} = .080 \pm .052$ ). The indirect effects of the other 3 exogenous variables on the entrepreneurial actions were not significant. Their values were not calculated because the direct effects of the exogenous variables on job satisfaction were not significant.

## DISCUSSION

Our focus has been on the antecedents, actions, and outcomes related managerial performance. The findings of this research effort suggest that work discretion and rewards/reinforcement lead to higher perceived job satisfaction and that this heightened satisfaction results in increased entrepreneurial actions. Specifically, there is an increase in the number of new ideas suggested, the number of new ideas implemented and the number of unofficial improvements made. These findings and the resulting model advance the research in the area of organizational antecedents and the viability of the CE process. The results indicate that greater emphasis on these antecedents can lead to more internal entrepreneurial behavior thus adding to the validity of such CE antecedents suggested by Hornsby et al. (2002) and others.

ENTREPRENEURIAL SUPPORT FOR RURAL SMALL, MEDIUM AND MICRO  
ENTERPRISES (SMMES) IN SOUTH AFRICA

## ABSTRACT

*A research project on small, medium and micro enterprises (SMMEs) support was initiated that recognised the alarming failure rate among SMMEs, especially in the rural areas. The aim of this project was to raise awareness of support for activities by rural SMMEs. Cognisance was given to the fact that some SMMEs had succeeded under the prevailing conditions. The first phase of this project sought to solicit the stories and experiences behind such successful entrepreneurs in the rural areas. The second phase, presented by this article, embraced a survey of 600 SMMEs from all six Limpopo provincial municipal districts. The purpose of the survey was, amongst others, to determine the profile of rural small businesses, assess required and availed support systems, and make recommendations for SMMEs stakeholder support. A response rate of 89% was attained. The findings revealed the following major trends: the general profile reflects 84% of sampled SMMEs to be owner-managed; 70% have 1 to 3 staff members and the majority of the businesses (71%) have been in existence for at least six years. The support available to the SMMEs sector is perceived to be generally weak with the exception of staff development training seen to be accessible by nearly 60% of the respondents. Nearly 80% of the respondents perceive finance to be inaccessible. The study recommended, inter alia, the strengthening of business chambers among rural businesses and the targeting of support systems mainly to the micro and very small businesses, which are in the majority in rural communities.*

## INTRODUCTION

Levitsky (1996:1) indicated that virtually all countries, at whatever stage of economic development, recognise the importance of small, medium and micro enterprises (SMMEs) and the need to support their development. SMMEs contribute more than 90% of employment opportunities in many countries, are responsible for revenue creation and poverty alleviation, and are a source for creativity and innovation (UNCTAD, 2003:3). The SMMEs sector, when adequately supported, could see many developing countries realise their dreams of improving their economies.

The main challenges facing many developing economies are unemployment and poverty. A Norwegian survey in March 2002 reported South Africa's unemployment rate to have risen from 6,7% in 1960 to 10,6% in 1983, to 33,7% in 1995, and to 45% in 2001 (Mahadea, 2003:3). Although SMMEs in South Africa account for 97% of all businesses, they contribute 25% of the gross domestic product (GDP), absorb 38% of the labour force and are responsible for 75% of new jobs (Netswera, 2001:32). Our country is characterised by high rural-urban influxes by young people and professional practitioners seeking survival and livelihood in cities (Kroon, 1998:36). The objectives of government and non-governmental organisations, including the World Bank, have been to reverse rural-urban migration and sustain rural development (I-Net Bridge, 2002). Rural entrepreneurs are trying hard to succeed against the odds. Many of these rural areas are characterised by population sparsity, remoteness, poor infrastructure, little or no access to vibrant markets, and many similar negative factors that impede rural economic development.

## PROBLEM STATEMENT

Some of the most significant problems currently facing South Africa are unemployment (45%) and rural poverty (71%), which have direct effects on other social ills such as crime and AIDS (Aliber, 2002:2). In tackling some of these problems, some rural dwellers start their own small business enterprises in an attempt to earn a living. A number of these SMMEs, however, end up failing (SBDC, 1996; Jackson & Alberts, 1998; AMC, 2004). Reasons that lead to failure include, amongst others, limited resources, inexperience in running and managing own enterprises, poor cash management and weak marketing efforts (Badenhorst, Cronje, du Toit, Gerber, Krüger, Marais, Strydom, van der Walt & Reenen, 1997:90; Barrie, 2003; Bizhelp24, 2004; AMC, 2004). It is argued that a lack of appropriate support is the main reason for the high failure rate of SMMEs in South Africa (Levy, 1996:11; Netswera, 2001:31).

The following are some important questions worth asking about SMMEs support in the rural areas:

- Are there support services for small businesses in the rural areas?
- Do rural entrepreneurs require support in running their businesses?
- Are small businesses aware of available support services?
- Do rural entrepreneurs make use of these SMMEs support services?
- What do small businesses think of their SMMEs support services?

The Limpopo province has been chosen as the study area for this research. The rationale behind selecting this province is that it has the highest rural population (89%) and an unemployment rate of 46% (Stats SA, 2000).

### **MAIN AIM AND OBJECTIVES OF THE RESEARCH**

The main aim of the study is to raise awareness of what SMMEs do in the rural areas of South Africa, and to solicit support to strengthen SMMEs activities.

Objectives of the research are as follows:

- To profile rural small businesses
- To assess the requirement for and availability of small business support
- To make recommendations to SMMEs stakeholders to support rural small businesses

### **GENERAL PERSPECTIVES ON RURAL SMME SUPPORT**

Rural areas are an increasingly important component of the national economy and are characterised by the importance of very small-scale enterprises, with over 90% of all rural firms defined as micro-businesses (COPIU, 2000). These small businesses are an integral part of the rural economy, and ensuring their continuing success is essential to developing and sustaining thriving rural communities (Warren-Smith & Dakin, 2002:1).

Many people choose entrepreneurship as a career for a variety of reasons. Scarborough and Zimmerer (2003:4) refer to the Dun and Bradstreet 19<sup>th</sup> Annual Small Business Survey conducted in 2000 that revealed some of the reasons that entrepreneurs go into business. Entrepreneurs who joined family business were the highest (41%); 36% wanted more control over their future; 27% were tired of working for someone else; 25% wanted to fulfil their lifelong goal; and only 5% had been downsized or laid off. Of the 25,5 million businesses in the United States, 90% are family-owned and -managed. The small business forms the biggest chunk of this sector (98,5%). Although some entrepreneurs start their enterprises when they are under 25 years of age, and others when they are over 44 years of age, the majority of entrepreneurs start their enterprises when they are between the ages of 25 and 34 (33%), and 35 and 44 (32%). The Small Business Administration (SBA) indicated that 20% of the businesses in the United States (US) are in retail, 40% in service, and 12% in construction industries. Those that are in wholesale are 8%, finance 8% and manufacturing 6%, i.e. all less than 10% (Scarborough & Zimmerer, 2003:12, 18, 20-22).

There are, however, constraints that hinder rural SMMEs from growing and developing in many countries. One of the many factors that has been identified as constraining rural business development is access to business support and advice (DETR, 2000; Hodge, 1999; Keeble, Tyler, Broome & Lewis, 1992). Lack of awareness (Rae, Ratcheva & Vyakarnam, 2000; Curran, 2000) of the value of business support amongst entrepreneurs, or problems arising from the accessibility of providers, with many located in urban areas (DTZ Pineda Consulting, 1999), may be attributed to lower SMMEs support in rural areas.

SMMEs support encompasses a wide range of support including business advice and information; training; financial assistance (Bridge, O'Neill & Cromie, 1998); and business networks and mentoring schemes (COPIU, 2000). Business advice and information incorporates generic business start-up advice and support, business planning advice, development support, and consultancy and advice on business plans and business promotion (Bennett, Robson & Bratton, 2001; Lowe & Talbot, 2000b; NRETS, 1996; Smallbone, Baldock & Burgess, 2000). Training ranges from generic skills training to business planning courses and management training (NRETS, 1996; Revolution, 2000), whereas financial assistance can consist of advice on raising finance, provision of grants and funding, financial planning and management (Curran, 2000; Revolution, 2000; Smallbone et al., 2000).

Training provides the opportunity for owner-managers to develop their management skills. However DTZ PIEDA Consulting (1999) reported that only just over a third of rural businesses use external training. Errington, Harrison-Mayfield and Bennett (1994) state that with training facilities predominantly located in urban areas, many rural businesses are significantly disadvantaged in terms of access, and many have little opportunity or funds to utilise formal training (Shropshire Partnership, 1999). Barclays bank (1998) reported that while 73% of small business owners believe training to be important to their business success, less than a third undergo training prior to starting their business, and only 30% have used training over the last three years.

Levitsky (1996:19) indicated that the reservoir of knowledge and experience in technology, management and marketing skills that could be of help to SMMEs is to be found in various elements of the business community and beyond. Private consultants in the country are one major group that can provide such support. Most private consultants, however, target larger enterprises or public bodies as their potential clients and provide less help to small business because of the high consultancy costs that SMMEs cannot afford. Levitsky further states that the independent group of local private consultants in most developing countries is relatively undeveloped, in many cases somewhat unreliable, and their services are not always of the quality standard to inspire confidence in potential clients. In some cases, the local consultant groups develop as branches or affiliates of international consulting organisations and the local operations are strengthened by more qualified and experienced expatriates. Professional staff from government offices, banks, large enterprises, universities, technical colleges, management and small enterprise development agencies usually all try their hand as consultants (full-time or part-time) in an effort to enhance their income, status and independence.

### **SMMEs SUPPORT IN SOUTH AFRICA**

Regarding constraints upon small business development, the South African government, in redressing the legacy of the past, initiated a wide-ranging consultation and research process. This process culminated in the production, in October 1994, of the Discussion Paper on *Strategies for the Development of an Integrated Policy and Support Programme for Small, Medium and Micro Enterprises in South Africa*. This document gave birth, in March 1995, to the White Paper on the *National Strategy for the Development and Promotion of Small Business in South Africa*. In 1996, the *National Small Business Enabling Act* was passed in parliament. Many other Acts that support the development and promotion of small businesses were also passed in parliament. Examples of such Acts are the *Skills Development Act 97 of 1998*, the *Preferential Procurement*

*Policy Framework Act 5 of 2000* and the *Mineral and Petroleum Resources Development Act 28 of 2002*. These pieces of legislation, amongst other things, support SMMEs in addressing the low skills levels, lack of markets, procurement, and unfavourable legal environment in the mining sector.

The White Paper (1995:12) acknowledges that small business, compared to big business worldwide, faces a wide range of constraints and problems, even in effectively functioning market economies. These constraints relate mainly to the legal and regulatory environment, access to markets, finance and affordable rental for business premises, the acquisition of skills and managerial expertise, access to appropriate technology, quality of the business infrastructure in poverty-stricken areas and, in some cases, the tax burden. South Africa's historical past, however, has exacerbated the situation, particularly for entrepreneurs in rural areas, and for women.

In addressing these constraints, the government created an enabling environment by putting the right policies in place whereby small businesses could thrive. The government acknowledged that the real engine of sustainable and equitable growth is in the private sector. The SMME support structures that started after 1994 were mainly the provincial SMMEs desks, the Ntsika Promotion Agency, and Khula Enterprise Finance Limited. The purpose of the provincial SMMEs desks were to provide SMMEs support in all the provinces. The Ntsika Enterprise Promotion Agency provides a wide range of non-financial services to local service delivery groups on a 'wholesale' basis, i.e. the delivery of resources to local providers that work directly with SMMEs. These services are offered by accredited local service providers and include institution-building of these organisations, training programmes for entrepreneurs, mentoring of individual firms, marketing, procurement advice, and technology assistance (Carana Report, 1999:25). Khula Enterprise Finance Limited provides 'wholesale' finance to the non-governmental organisations (NGOs) that offer micro loans to starter entrepreneurs. This is done through the development of Retail Financial Intermediaries (RFIs) that are financially sound, with the commitment and the capacity to serve the SMME sector, with special emphasis on its previously disadvantaged population (Carana Report, 1999:42; Ladzani, 2001:235).

The current government initiatives do not imply that there were no SMMEs support structures in place during the minority rule government. There were a number of programmes and small business-support policies during that time. Semi-government institutions such as the Development Bank of Southern Africa (DBSA), the Small Business Development Corporation (SBDC), and the Industrial Development Corporation (IDC) developed as financiers and SMMEs-support agencies. Many of these institutions that developed over the years were, unfortunately, mostly racially and gender-biased. Regional development corporations, whose focus was largely to develop black entrepreneurs, made a limited impact. Little co-operation was extended directly to the black business sector from central government level. An example is the public tendering system that favoured established and larger businesses (largely white businesses). It was very difficult for newly established businesses to enter the public tendering system. University-based small business units, and the private and non-governmental organisation (NGO) sectors were also involved in small business development but were not effective in their overall impact, were often in competition with each other, and were frequently uncoordinated. It is against this background that the call for co-ordination, co-operation and a

clear national strategy framework increased over the past few years. Lack of legitimacy made it impossible for the previous government to fulfil such a role (White Paper, 1995:13-14).

## **METHODOLOGIES AND SAMPLE REALISATION**

A stratified sampling method was used for the research. The strata were the six municipal districts of the Limpopo province. From these municipal districts, a sample of 600 respondents was selected and a total of 100 questionnaires administered in each stratum. Participating SMMEs in each stratum were purposefully selected. The selection criterion was aimed at selecting only businesses that were deemed established, that had experiences and exposure worth learning from, and that had been in existence for at least three years.

In total, 534 questionnaires were successfully administered from the 600 questionnaires intended, giving a response rate of 89%. Because the total SMMEs population in the Limpopo province is unknown, an infinite population size was used to calculate the margin of error ( $ME = \sqrt{P*Q/n*SD}$ )<sup>i</sup>. Taking refusals and spoiled questionnaires into account, a maximum margin of error of 1.36 (p=0.5) at a standard deviation of 1.96% was realised. The realised sample size reflected the following percentile responses from each stratum, i.e. Capricon 13% (70); Mopani 18,8% (100); Waterberg 12,4% (66); Vhembe 18,8% (100); Sekhukhune 18% (96); and Botlabela 19% (102).

## **RESEARCH FINDINGS**

### **The Profile of Sampled SMMEs**

The age profile of the SMMEs operators or managers interviewed ranged from less than 25 years (3%), 26-30 years (10%), 31-35 years (15%), 36-40 years (16%), 41-45 years (15%), to 46 years and above (41%). The gender composition was 79% males and 21% females, and the academic qualifications were standard 5 (16,9%), standards 6-8 (29%), matriculation certificates (25,4%), post-matriculation certificates (10,2%), diplomas (11,1%), degrees (3,4%) and postgraduate degrees (3%). The racial composition was 1% whites, 2% Indians and 97% blacks. The ethnic composition of the black-owned SMMEs included Pedi (46%), Tsonga (30%) and Venda (18%), which are the main ethnic groups in the Limpopo province [N=531].

The findings of this research indicate that 84% of the surveyed SMMEs are owner-managed, 8% are run by appointed managers, and the rest by family members. Ownership of these businesses is primarily sole proprietorship (70%), followed by family businesses (16%), partnerships (13%) and close corporations (1%). More than half of the interviewed businesses are in the retail sector (51%), followed by manufacturing (12%), agriculture (9%), entertainment (3%), transport (3%), arts and crafts (1,5%) and property (0,2%) [N=410].

Registered (and therefore tax-paying) SMMEs amounted to 71% and the rest were unregistered businesses. The existence ages of these SMMEs were 3 years (12,3%), 4-5 years (16,9%), 6-10 years (30,5%), 11-20 years (27,3%) and over 21 years (13,1%) [N=528]. The staff compositions at the start were as follows: less than 5 staff members (84,4%), 6-10 (8,9%), and 11-50 (4,4%). Current staff membership, however, stands at 1-3 staff (70,4%), 4-6 (22,1%) and 7-9 (7,5%)

[N=443]. Whereas 4,4% started with employees between 11 and 50, there were, however, no SMMEs with these numbers during interviews.

Motives for starting businesses ranged from, among others, unemployment (30,8%), a need to support communities (22,7%), and a dire need to eradicate poverty (28,6%), to interest in owning a business (17,9%). Although unemployment seems to be the main incentive for starting a business, 53,5% of sampled SMMEs started their businesses while employed and 46,5% while unemployment [N=525]. Of all the businesses that responded, 84% did not receive funding for start-up purposes, 9% received loans and 4% were funded by family members and relatives [N=522]. Of the SMMEs that received funding, 48% received this from the Land Bank followed by development corporations (11%), the Independent Development Corporation (IDC) (5%), and commercial banks (3%). At start, 49,9% of the businesses had business plans – currently only 51,4% have business plans [N=515]. Of those businesses that have business plans, 92% were compiled by owner-managers and only 8% made use of consultants. Only 68,7% of the owner-managers have knowledge of how to compile a budget. Of the businesses that compile budgets, 84,8% do so monthly, 7,7% quarterly, 2,5% twice-yearly and 5% yearly [386].

Assets of the businesses interviewed range from less than R50 000 (39,2%), R50 001 - R500 000 (41,9%), R500 001 - R1mil (9,1%), R1mil - R5mil (9,5%), to more than R5 million (0,5%) [N=528]. Monthly business turnover ranges from less than R10 000 (60,5%), R10 000 - R20 000 (18,4%), R20 001 - R30 000 (8,6%), R30 001 - R40 000 (2,3%), R40 001 - R50 000 (1,1%), R50 001 - R60 000 (0,6%), R60 001 - R70 000 (0,4%), R80 001 - R90 000 (0,4%), R90 001 - R100 000 (0,8%), to more than R100 000 (7%) [N=526].

Infrastructure includes availability of telephones (79%), electricity (84,6%), fax machines (4,7%), personal computers (4,7%), email (1,5%); Internet addresses (1,3%); printers (3,7%); running water (42,7%) and flushing toilets (12,7%) [N=452]. Businesses that serve the local markets are 83%, provincial markets 8,4%, both local and provincial markets 1,7%, international markets 0,4%, and both national and international markets (6,5%) [N=523].

### **Availability and Accessibility of SMMEs Support Systems**

Business support received after start includes finance (72,7%), training (17,8%), tendering and procurement (6%), marketing information (3,2%) and business counselling (0,3%) [N=348]. Utilised support from consultants is mainly in financial management (12,6%), marketing management (14,7%), operations management (15,2%), administrative management (14%), purchasing management (14,4%), human resources management (13,8%), and public relations (14,8%).

SMMEs that have experienced financial problems in the past made up 62,4% [N=534]. Reasons for the SMMEs' bad financial state and experiences included, among others, default payments by debtors (31,6%) and theft of organisational resources and products (14,9%).

Owner-managers that have undergone training on general management are 13,1%, and on financial management 86,9% [N=518]. The type of training undergone by employees includes customer relations (4,8%) and merchandising (95,2%) [N=482], while on-the-job employee training is a preferred mode of training (58,8%) (N=475).

Product advertising is perceived to be a costly method of attracting customers by 75,9% of the interviewed businesses – only 13,5% disagreed [N=518]. Respondents were asked about the kinds of support that their SMMEs perceive to be available or accessible, and their impressions are indicated in Table 1.

---

Table 1 about here

---

Of the support reflected in Table 1, finance and training for skills development were ranked the two most important support system requirements by 75,9% and 73,1% of respondents respectively.

### **DISCUSSION OF FINDINGS**

The South African government commends the SMMEs sector for contributing 25% to the national GDP, 38% to employment and for being responsible for 75% of new jobs (Katz, 1997). The SMMEs could contribute more to the national GDP and employment considering that SMMEs in countries less developed than South Africa contribute much higher proportions to GDP and employment (APEC, 1994; Katz, 1997; OECD, 1997; UNCTD, 2003). The government therefore started creating an enabling environment by putting the right policies and support institutions in place, among them Ntsika Enterprise Promotion Agency (NEPA) and Khula Enterprise Finance Limited, to enable SMMEs to thrive (White Paper, 1995:12). Khula's long-term job creation objectives were to provide broader access to finance for small businesses, as opposed to the micro-survivalist category (Carana Report, 1999:42). Although the Carana Report revealed that Khula's activities were disproportionately concentrated in the micro-survivalist sector through its Retail Financial Intermediaries, its findings are that this sub-sector in the rural areas received very little funding support.

Because access to finance is perceived to be critical to success, the private banking sector has received continued criticism for its inflexibility in helping the development of the SMMEs (Levy, 1996). Government-sponsored financial institutions such as the DBSA, although helpful, have also failed to support the entire SMMEs industry and its diverse needs (Macleod, 1995). It is important to note that 58,9% of respondents from this survey believed that the banking sector is still unwilling to provide financial support even though finance is the biggest problem facing more than 87% of the respondents. For lack of financial support, many SMMEs owners started their businesses without any external funding (84%) and only a few (9%) received loans. Only 3% of the 9% funding is from commercial banks. Findings from Netswera (2001:6) reveal availed support systems to be more effectively accessible if complemented by a publicity strategy. Lack of knowledge of the available support systems can possibly be a factor hindering accessibility in terms of, among others, language and proximity of support institutions, especially for the rural entrepreneurs where most institutions are remotely situated. The little or no support received thus far has been attributed to the lack of access to information about such support systems.

The findings revealed that only 3% receive marketing support, 6% tendering and procurement support, and 18% training support. Although many small business owners believe that training is important, few undertake training prior to starting their businesses. This is supported by Barclays (1998) who reported 73% of small business owners to believe that training is important to their business success, although less than a third undertake training prior to starting their business, while 30% had been trained over the last three years.

Poor support can be attributed to the type of ownership and size of business. Most of the businesses interviewed are owner-managed (84%) and have a staff complement of 1-3 (70,40%). This scenario hinders most owner-managers from leaving their enterprises to seek training, advice, marketing, and tendering and procurement information. Most owner-managers are only free from their business duties outside of working hours, by which time SMMEs support service providers of training and financial institutions specifically, are closed. 90% of businesses in the United States are family-owned and -managed (Scarborough & Zimmerer, 2003:18). In this study, 16% of the interviewed businesses are family-owned and -managed. Family support in running successful enterprises has numerous spin-offs such as shared values, power and the enforcing of family ties. Providing family members with the necessary skills is therefore central to the success of a business venture.

The total assets of the interviewed SMMEs are mainly R1 million and below (90,1%) and the remainder (9,9%) are above R1 million. Only 0,4% have assets worth more than R5 million. Taking into consideration that the staff complement of all interviewed businesses falls below 10 employees [1 – 3 staff (70,4%), 4 – 6 staff (22,1%), 7 – 9 staff (0,5%)], all SMMEs interviewed are therefore categorised under micro- and very small businesses. This implies that most SMMEs in the rural areas are micro- and very small businesses. The inability of the micro- and very small businesses to develop into small businesses is a cause for concern considering that 70,9% of the respondents have been running their businesses for more than six years. Taking cognisance of the fact that the micro- and very small businesses do not pay tax, it also implies a loss of revenue to the government and non-accounting of their contribution to the national GDP.

## **CONCLUSIONS AND RECOMMENDATIONS**

It can be concluded that in the midst of a third of the country's unemployment, the SMMEs industry is the main option for the survival of many rural communities. An SMME profile suggests competition in this industry to have gained huge momentum. It is becoming more difficult to vie for support resources and growth from the micro- to small business level. Since the majority of SMMEs are sole proprietors (70%), the attaining of support systems is weakened considering the tendering and subcontracting requirements for diversity in terms of ownership, gender, race and age groups, among others. It is important that SMMEs owners receive information and training on the importance of diversity of ownership – a task that can easily be fulfilled by the business chamber where available.

No affiliation to a business chamber amongst the SMMEs is an impediment to development and co-ordinated support lobbying. Also worrisome for this sample is that only 6,7% belong to a business chamber. It is important, especially for the development of the rural micro-enterprises that SMMEs jointly organise, lobby for support and implement joint projects, where necessary.

Although numerous SMMEs support institutions are in place, including the various support mechanisms and programmes, such information is relatively unknown to the emerging rural entrepreneurs. It is thus important for government and other support agencies such as Khula, Ntsika and the DBSA, among others, to move from an institutional set-up philosophy towards capacitation, support campaigns and reach-out programmes. Even more important, the evaluation and publicity of the inroads made thus far by the SMMEs support institutions would be motivational in giving an impression of the existing support possibilities and their successes.

Since the country's main problems of unemployment and poverty are essentially rural problems, and considering that the majority of the SMMEs in the rural areas are micro- and very small businesses, support systems should be designed and targeted at these sub-sectors. However, since some micro- and very small businesses are not registered, efforts should be aimed at formalising the sector and leveraging both training and financial support systems.

Despite the legislated SMMEs definitions, and scanty success factors, there seems to be a gap for continuous surveys and audits of the SMMEs industry. The lack of information in the sector impedes, among others, planning the industry's national support systems, and giving a continuous account of the contributions that the industry makes towards employment and GDP. Because of a lack of this information, it is often difficult to know the SMMEs' numbers, their successes and failures on an annual account, as well as the successes and failures of available support systems.

## ABSTRACT

This paper extends prior work on using agency and stewardship theories as complementary models of man, hence organizational behavior. We apply these theories in a new context, the business incubator—entrepreneur tenant, in order to enhance our understanding of this complex relationship. Entrepreneurs rely on incubators to provide them with access to critical resources, while incubators rely on entrepreneurs to build and maintain its reputation as a vital community economic engine. Our model of the incubator—tenant relationship takes into account the role that both asymmetrical and symmetrical goals play in turning inputs into outputs, thus start-ups into successful graduate companies. We posit that while on their own neither theory adequately describes the incubator—entrepreneur phenomenon, together agency and stewardship theories provide a great deal of insight in describing this phenomenon.

## INTRODUCTION

Since the first building, turned business incubator, opened its doors in 1959, incubators have provided a haven for entrepreneurs looking to lower the cost of hatching and growing their enterprises. Many business incubators have become an integral part of their local communities, stimulating employment opportunities and economic growth. Despite this tremendous growth in the popularity of business incubators no research could be found that examines the complex incubator—entrepreneur relationship which goes beyond that of landlord and tenant arrangement. We posit that this interdependence introduces the potential for maximizing behavior by at least one of the parties, following the precepts of agency relationship even when the incubator is a public, not-for-profit or a government sponsored one. Jensen and Meckling (1976) argue that “agency costs arise in any situation involving cooperative effort” (p. 6).

However, the agency model cannot account for all the nuances and variations-on-the-theme that exist in the incubator—entrepreneur relationships. Incubator managers often act as guardians or stewards by assisting and protecting these entrepreneurial and fragile startups. The incubator manager’s motives are often aligned with the entrepreneur’s objectives, as incubator managers are judged by, among other things, the success of their tenants. Agency theory provides little explanation when interests by the parties are aligned, therefore it cannot be exclusively relied upon to explain the complex nature of inter-organizational relationships (Davis, Schoorman, & Donaldson, 1997a). Hence, agency theory cannot provide a complete explanation for the incubator—tenant relationship. Therefore, we need another model that can fill in this gap. Stewardship theory provides an additional insight into the incubator—tenant relationship as it has been introduced to explain situations where parties are not motivated by individual goals (Davis, Schoorman, & Donaldson, 1997a).

We use both agency and stewardship theories to answer our research question “How do agency and stewardship theories enlighten this complex relationship?” Both agency and stewardship theory deal with aligning interests in the manager—principal relationship. However, each approaches human behavior and motivation differently. The agency model views man as being extrinsically motivated through tangible rewards such as salary, bonuses, and other commodities that have a market value (Davis, Schoorman, & Donaldson, 1997a), while according to stewardship theory, stewards maximize their utility by acting the organization’s best interest,

thus, they are more intrinsically motivated through rewards such as growth and achievement (Tosi, Brownlee, Silva, & Katz, 2003).

## **LITERATURE OVERVIEW**

According to the Small Business Administration (SBA, n.d.) small businesses employ over 50% of the U.S. workforce and account for roughly 23 million companies in 2002. Entrepreneurial ventures are even more of an economic engine in the high-technology sectors, as they directly account for 39 percent of the jobs (SBA, n.d.), and also provide Fortune 500 companies with access to many leading edge products through strategic alliances and other inter-organizational partnerships that large firms would not otherwise benefit from. One problem that young ventures face is high failures rates due largely to under-capitalization and a lack of management expertise. These problems are amplified in the high-technology sectors, as these firms are extremely expensive to start-up and many are run by the research scientists that often have limited business experience.

Business incubators have evolved as a solution designed to stem the flood of failures by small business and enhance survival rates of start-up businesses are doing just that. Most incubators assist entrepreneurs move along the road to self-sufficiency by dispensing advice to young firms, providing access to free or low cost consulting, access to venture capital and angel financing, and a network of other business people. These services are generally provided at or below market rates for a fee that generally includes monthly rent and sometimes a small equity stake in the budding venture. Thus, the relationship between the incubator and entrepreneur is quite important and complex.

Incubator managers serve the greater community and their institution's board, owners and other financial backers. For example, the incubator desires maintain a high occupancy level. One manager described a conflict between maintaining a high occupancy rate of high potential ventures, while improving the center's number of successful graduates. Thus, a tension between the two party's goals may arise. These conflicting roles can place a strain on incubator—tenant relationships. The tension is not just from the incubator side. We found that in some cases the incubator manager felt that entrepreneurs kept them at arm's length, as they were in the dark regarding the entrepreneurial firm's progress. When business incubators are profit making entities, owned by business concerns – developers or corporations, agency theory becomes even more relevant, as the incubator becomes more concern with earning a profit on its investment. However, while incubator managers may look out for their own self-interest, on some level they recognize that the survival of the incubator depends on the survival of the other stakeholders especially their tenants (Fama 1980).

### **The Agency Perspective**

Agency theory (e.g., Jensen & Meckling 1976, 1994) holds that people are rational and seek to maximize their individual position, thus utility. According to this theory contracts are used by principals when employing an agent to perform tasks on their behalf. A popularized illustration of the principal—agent relationship has been the stockholder as the principal and CEO as the agent. However, this relationship comes at a cost to the principal, as it is possible that the agent will not always have the principal's best interest in mind due to maximizing behavior. The

principal can provide incentives and monitor the agent's behavior; however, this increases the cost of conducting business. In the case of CEO's, often their salaries are linked to long-term company performance. Unfortunately, this has led to a number of recent financial scandals in some of the nation's largest companies, and brought a new debate about management theories to the fore. (Ghoshal 2005). In addition, it is generally impossible to ensure that the principal will always agree that even the best intended agent decisions will be optimal for zero cost (Jensen and Meckling 1976a).

While agency theory has been applied to entrepreneurial and other organizations (e.g., Jones & Butler 1992; Falbe & Larwood 1995; Norton 1995; and Arthurs & Busenitz 2003), it has yet to be applied to the relationship between business incubators and entrepreneurial start-ups. Complicating a simple application of agency theory to the business incubator context is the myriad of stakeholders and, at times, the conflicting interests of such stakeholders and the roles they play. An incubator's management faces a daunting task having to maneuver among the numerous stakeholders including tenant-entrepreneurs (present and potential), incubator employees, mentors, volunteers, the incubator's board of directors and the community-at-large. Incubator managers are saddled with the often difficult task of differentiating between entrepreneurial start-ups that are likely to succeed, hence attractive, from those that will never grow beyond the incubator's setting. Potential tenant-entrepreneurs are likely to provide the tenant screening committee or the incubator's management with a rosier picture of what their chances of success will be. Therefore, due diligence work that is required to screen tenant applications involves explicit research costs in order to decrease future agency costs and current information asymmetry (Norton 1995, p. 20). In addition, some entrepreneurs look at their partnership with the incubator more through the lens of agency theory. They are wary of providing the staff with too much information and are very careful when participating in incubator sponsored activities and services. The stewardship model offers a different explanation for motivations, "which may include the interests of all relevant stakeholders" (Preston 1998, p. 9).

### **Stewardship Perspective**

Stewardship theory (e.g., Davis, Schoorman, & Donaldson 1991, 1997a) adds another dimension to studying the inter-relationships between incubators and entrepreneurs. According to this theory, individuals are motivated to behave in a manner that is in the best interest of their organization (Donaldson and Davis 1991). They attempt to align their goals with the goals of their organization. Performance variations, according to the theory, often have to do with the structural situation in which the actor works within, thus there must be sufficient resources and means to facilitate good action (Donaldson & Davis 1991). Incubator directors, especially those of the not-for-profit and public incubators often consider themselves as stewards of their fledging tenants. In addition, the best interest of the incubator and the community immediately surrounding it is linked with the overall success of the tenant-entrepreneurs. Therefore, both incubator and tenant would like to see the startup grow and prosper.

One important measure of an incubator's success is the number of its tenants-graduates and their respective success rates. Graduates' success also contributes to the local economy and job creation in the surrounding community. The incubator can therefore be credited for that positive

economic impact and value to the local geographic area. Thus, goal alignment seems to be critical in order for all stakeholders to obtain their goal. In dealing with multiple stakeholder groups with competing objectives, stewards are motivated to make decisions they perceive in the best general interest of the group in order to provide the most overall benefit (Davis, Schoorman, & Donaldson 1997a). Thus, according to stewardship theory, the manager of the incubator and the entrepreneur benefit most when self-serving behaviors are put aside (Davis, Schoorman, & Donaldson 1997a) and the two parties collaborate.

## **Outside Funding and Revenue Sources**

Business incubators get their operating funds from a variety of sources, which are often a function of the incubator's ownership and mission. In the case of publicly owned incubators funding comes from local and state tax revenues, private donations and contributions of in-kind services, grants from foundations, state and local economic development bodies and federal grants programs.

University owned and operated incubators get funds from all the above sources – albeit at different proportions, as well as university sources both actual funding and in-kind contributions such as space, computer facilities and services, research grants, graduate assistants etc.

Private incubators get most of their funding from private funding sources which may include corporations, individual or groups of angels, venture capitalists and developers. They may also get some public funding or assistance from State and local organizations. To the extent that the missions of the different types of incubators reflect the interests of the funding sources there will be the issue of the congruency of the goals between these funding sources, represented by the incubator board and managers and the tenant entrepreneurs. We posit that an incubator's mission has an effect on whether it tends to be more agency- or steward-like in its relationships.

*Proposition 1: The business incubator's mission affects the degree that incubator managers take more of an agency or stewardship perspective in relation to their tenants.*

*Proposition 2: The type of perspective view (agency or stewardship) that the incubator management takes in relation to their tenants affects the incubator's mission or purpose.*

*Proposition 3: The amount of outside support and revenue the business incubator receives from non-tenant sources (e.g. affiliate companies and anchor tenants) play a role in determining whether incubator managers take more of an agency or stewardship perspective in relation to their tenants.*

*Proposition 4: The type of outside funding sources that the business incubator seeks depends on whether incubator managers take more of an agency or stewardship perspective in relation to their tenants.*

## CONCLUDING REMARKS

Our central purpose has been to extend previous work that has used agency and stewardship theories as complementary approaches, rather than arguing that one is better or more relevant than the other. In fact, in her “excellent review” (Albanese, Dacin, & Harris 1997, p. 611) of agency theory, Eisenhardt (1989) recommends that it be used with complementary theories, as the theory presents view of organizational life that is valid, but incomplete (p.71). In addition, we sought to extend these theories to the context of the business incubator—entrepreneur relationship.

Our observation regarding the shifting roles that these theories play in the incubator-tenant relationship is not far flung. The move from an agency relationship to stewardship and back, reflects both the changes of interests over time and the dynamic nature of interactions between organizations (Davis, Schoorman, & Donaldson 1997b). This dynamic relationship demands that theory focuses more upon the task being performed rather the initial relationship and that agency relationships must be viewed through a lens that can accommodate the shifting of interest alignment (Albanese, Dacin, & Harris 1997). As Albanese and colleagues (1997) put it, “[T]oday’s “agent” may be tomorrow’s “steward,” or vice versa” (p. 611). In addition, Leblebici & Fiegenbaum (1986) point out that, managers must deal with multiple constituencies some of which they are members, thus, “To define the manager as an agent who owes reasonable effort and unswerving loyalty to a specific class of principals becomes logically impossible” (p. 496).

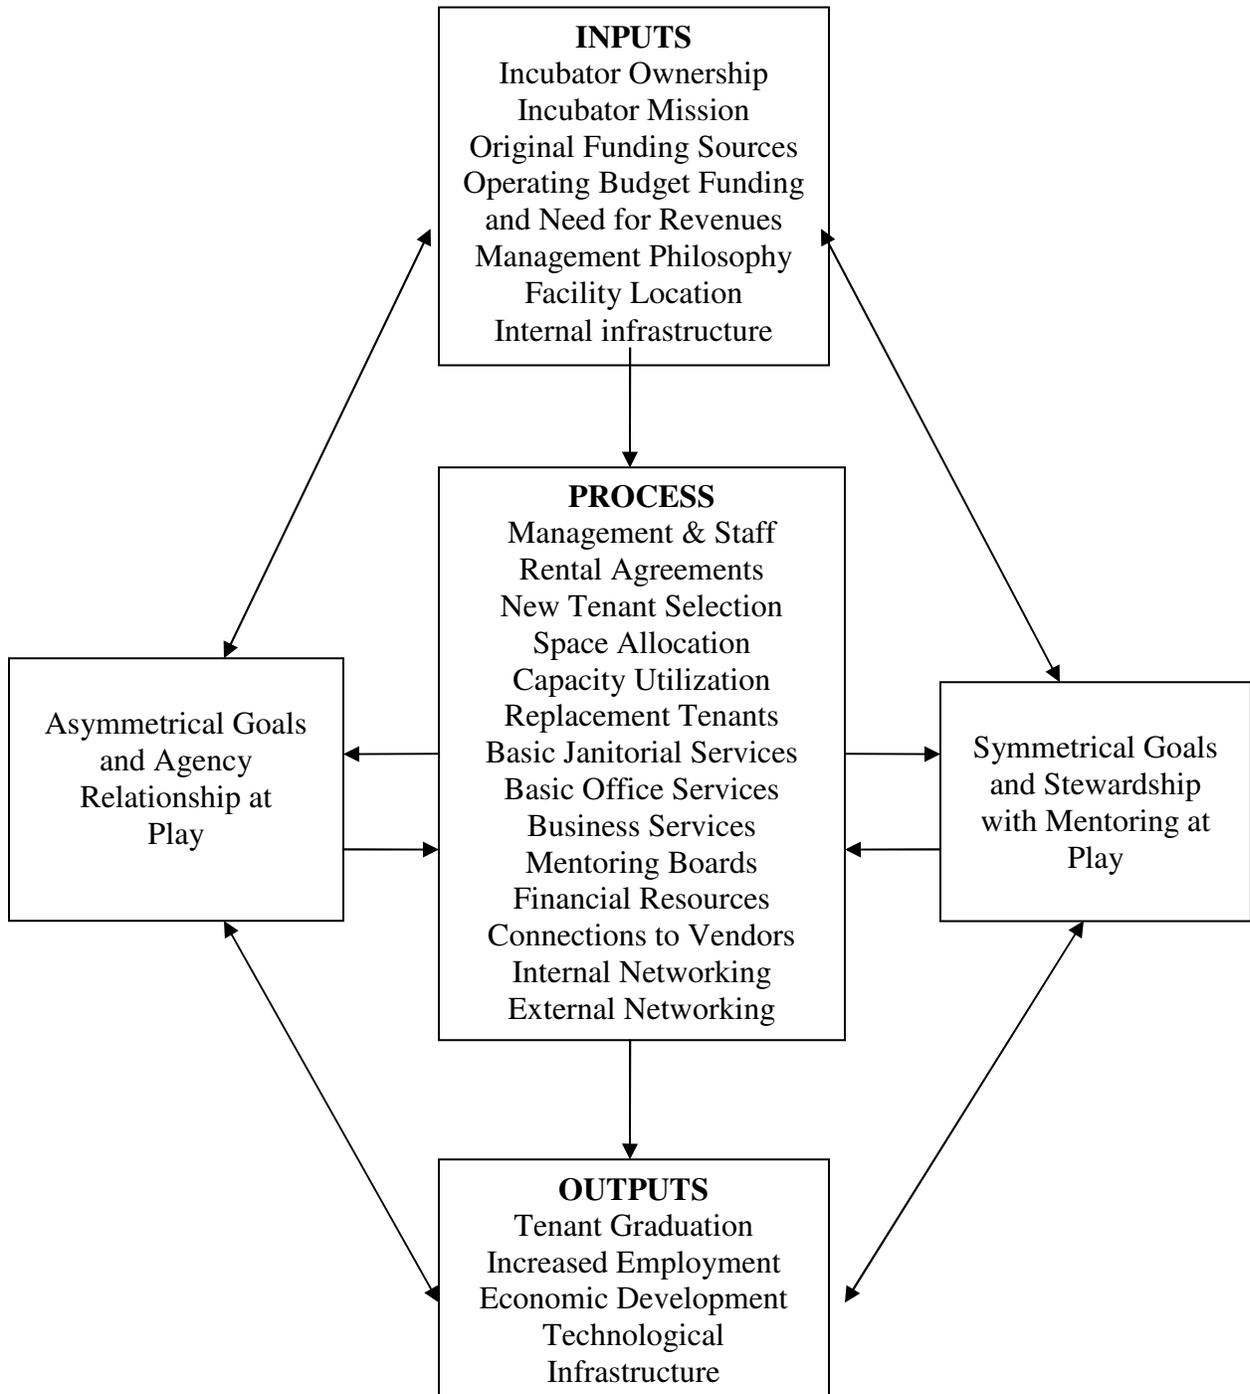

We call for research that studies the dynamic relationship between business incubators and their entrepreneurial tenants. Such research should study the phenomena over a period of time, rather at one particular point. We also recommend that researchers carefully consider the incubator’s mission and the type of firms that the incubator attracts. We posit there may be differences between low technological and high technological start-ups in terms of the applicability of these theories to the relationship.

Our research aim at exploring the strategic implications of spin-off processes for small and medium size enterprises (SMEs). Building on three in-depth case analysis, our research shows how owner-managers of SMEs have been able to turn what was initially a disruptive and threatening event into a value creating process, enhancing the competitive advantage and performance potential of their company.

For instance, the first case shows how a spin-off enabled an owner-manager to seize new opportunities in an emerging market by leveraging his relation with creative employees preparing their departure from the firm. The second case depicts how it helped secure the outsourcing of peripheral but critical activities of another SMEs. The third case illustrates how a spin-off simultaneously favoured employee's mobility and helped secure access to critical human resources. On the whole, our research tend to confirm that, in the context of SME, spin-offs can constitute powerful strategic tools.

However, for this to happen, the owner-managers have to display certain attitudes and competencies such as – a) encouraging and integrating individual initiatives, b) strong personal involvement in the spin-off process and c) in depth knowledge of the entrepreneur and the entrepreneurial process. These behaviors are enabled by SME's organizational characteristics such as, simple structure and processes, actors' proximity and centralized leadership.

### INTRODUCTION

Spin-offs – the process by which employees of an established organization leave this organization in order to create a new one – are a common phenomenon. In certain industries, such as management consulting, they even constitute the prevailing mode of entry (Garvin, 1983). Spin-offs are an inevitable by-product of Corporate Entrepreneurship programs and as such rather frequent in hi tech companies where employees are strongly encouraged to develop new activities. In 1998, corporate spin-offs represented almost 13% of all new firms created in Europe (European Commission, 1999).

Yet the strategic implications of spin-offs are understudied. We don't know how spin-offs affect the competitive position and performance potential of "mother" companies. This key question has not been thoroughly addressed in the literature which focuses either on macro aspects, such as the

impact of spin-offs on national competitiveness and employment or on micro aspects, such as their financial and human resources implications, neglecting overall firm implications. Among practitioners, spin-offs are generally associated to the loss of valuable employees and the emergence of new competitors and therefore seldom seen in a good light. In Europe, spin-offs are also connected with downsizing measures and are viewed by most managers essentially as outplacement tools.

Spin-offs, however, can be effective strategic tools. Examples stemming from the Japanese industry (Ito, 1995) but also from French Small and Medium Size Enterprises (SMEs) – the subject of our ongoing study – provide solid evidence in support of this statement.

Through the presentation of three selected cases studies, we will show how, in a variety of situations, owner-managers of SMEs have been able to turn what was initially a disruptive or even a threatening event into a value creating process, enhancing the competitive advantage and performance potential of their company.

### **SPIN-OFFS IN THEORY AND PRACTICE**

Spin-offs are an understudied phenomenon. A review of the literature produced on both sides of the atlantic reveals that A journal articles on spin-offs are less than a dozen and that the bulk of spin-off literature is constituted by colloquium presentations, working papers and official reports (Pirnay, 1998).

Though most spin-off definitions share common basic features – spin-offs “take place in an established organization and involve one or few of its members who leave the organization to create a new organization” (Pirnay, 1998) – they also diverge widely according to cultural factors (Pirnay, 1998). American literature, for example, apprehends the spin-off as a spontaneous phenomenon and focuses on the individuals that engage in it. For Garvin (1983), spin-offs are “new firms created by individuals breaking off from existing ones to create companies on their own.” On the contrary, European and French literatures in particular, tend to view spin-offs as the result of a deliberate corporate practice and focus on the “mother” organization. Bruyat (1989) defines spin-off (“*essaimage*”) as “a voluntary practice by which a company encourages and helps employees creating their own business.”

The questions investigated are also very different. An important stream of the American literature centers on the impact of “spontaneous” spin-offs on shareholder’s value (Schipper and Smith 1983; Aron, 1991; Woo, Willard and Daellenbach, 1992). In Europe, research has attempted to measure the impact of “induced” spin offs on headcount reduction and company performance (Laurent and Helderle, 1998; Rocchi, 1998) as well as national competitiveness and employment (European Commission, 1999). However, both sides have equally and largely overlooked the strategic implications of spin-offs.

From practitioners’ point of view, spin-offs obviously constitute major threats when they result in the departure of valuable employees and the emergence of direct competitors,. In the consulting industry, for instance, spin-offs are a common and much feared occurrence that established firms try to contain. In Europe, furthermore, spin-offs are closely associated to downsizing measures and managers of large established firms tend to view them as a “humane” outplacement tool,

which hopefully will not concern them in the near future. In synthesis, we can say that most practitioners view spin-offs as a phenomenon they have no reason to encourage unless their goal is to reduce headcount...

The position that researchers and practitioners have adopted up to now, seems to us somewhat restricted. We know for example that spin-offs can bring into being valuable suppliers, clients or partners (Johnsson and Hägg, 1987; Johannisson et al., 1994). Ito (1995) has shown that Japanese corporations used spin-offs strategically i.e., “as flexible alternative for survival in a highly competitive environment” which allow them to “satisfy corporate stakeholders.” He argues that the “mother” company and its spin-off, tied by financial participation and strong personal relations constitute a loose, adaptive organizational form, and a favorable compromise between hierarchy and markets (Ito, 1995).

To the extent they allow managers to redefine their company’s domain, boundaries and network of alliances in response to emergent threats and opportunities, spin-offs can enhance organizational flexibility and resilience and constitute valuable strategic tools. Our ongoing study on Spin-offs in the Context of SMEs provides some interesting empirical evidence in support of this proposition.

#### **UNDERLYING ASSUMPTIONS, SCOPE AND METHODOLOGY OF THE STUDY**

Viewed as an organizational type, SMEs share the following characteristics: limited resources and small size (MacMillan, 1975 ; Robinson and Pearce, 1984); simplified and informal structures and processes (D’Amboise and Muldowney, 1988) and clear leadership embodied in a centrally positioned owner-manager (Deeks, 1976 ; Charan et al., 1980 ; Welsh and White, 1981). Taken together, these characteristics should enhance the capacity of SMESs to set up innovative and flexible arrangements that would be out of the scope of larger, more bureaucratic firms.

Strategic spin-offs, which fall in this category of arrangement, are also the outcome of an entrepreneurial process, harbored and sometimes deliberately supported by the “mother” company. Strategic spin-offs can in fact be viewed as a special case of Corporate entrepreneurship, “the process whereby an individual or a group of individuals, in association with an existing organization, create a new organization or instigate innovation or renewal within the existing one” (Sharma and Chrisman, 1999). It is an emergent process in which individuals, as well as chance and improvisation (Burgelman, 1983; Kanter, 1985; Stevenson and Gumpert, 1985) play a critical role. Dealing with such processes is generally out of the scope of large, bureaucratized firms, which are unable or unwilling, for their most part, to provide timely and individualized support to what they generally consider marginal initiatives.

Thanks to their organizational characteristics, SMEs should be better at supporting and exploiting these processes. Their limited resources push them to look for external resource providers and to create and maintain privileged links with them, even if this leads to blurred organizational boundaries. The flexible and informal structure of SMEs provides a more supportive milieu for the largely ad-hoc structures and processes that characterize entrepreneurial ventures. The proximity of organizational actors, as well as the significant impact of any employee’s action or

project on the whole organization, favor an early and thorough assessment of the project's pros and cons by top management. Finally, the presence of a centrally positioned owner-manager simplifies and accelerates the decision to support or not the venturing project. For the aforementioned reasons, we hypothesized that SMEs constituted a favorable context for the study of “strategic spin-offs”.

More precisely, our goal was 1) to observe how SMEs dealt with spin-offs, adopting a top management perspective, 2) to identify the processes involved and 3) to assess their impact on performance. We adopted a retrospective and in-depth approach, which necessarily reduced our sample to a small number of firms. In the absence of database on spin-offs in the SME context, we proactively solicited an extensive panel of private and public business actors belonging to chambers of commerce, local incubators and entrepreneurs associations. They were asked to name SMEs and individuals involved in spin-off processes. Within three months, we were able to identify twenty-five SMEs apparently involved in spin-offs. We contacted the owners and the entrepreneurs in order to establish whether this involvement was recent and whether the key actors were accessible and willing to be interviewed. This was the case for fifteen SMEs. These fifteen SMEs, all of them French, represented a wide panel of industries. Data was gathered mainly through semi-structured interviews with the two main groups of actors – the owner-managers of “mother” SMEs and the entrepreneurs at the origin of spin-offs. When necessary, complementary interviews were conducted. In total, forty interviews were performed.

### **PRESENTATION AND ANALYSIS OF THREE REPRESENTATIVE CASE STUDIES**

The three case studies we now are going to present and analyze, illustrate each one of the three basic motives of “strategic spin-offs” in the context of SMEs.

- *The Teemo → Optix Case: Rejuvenating aging core competencies*

Teemo is a family business, which has been producing and selling mechanical fluid pumps for industrial use, mainly in France, for more than fifty years. In the late nineties, the owner-manager of Teemo was facing a slow but constant erosion of his main business due to the increased maturity of both technology and market. As margins started to decline, he decided to look for substitute products and technologies. To do so, the owner-manager of Teemo strongly involved all the managers of the company. After a long debate, the majority agreed that the technology of the “immersed rotor pump”, which guaranteed water tightness, was the most interesting and suitable one in terms of functionality, market and profit potential.

Teemo, however, possessed only part of the required knowledge and skills and was therefore not capable of internally developing and mastering this complex technology. All the managers of the company, and in particular its technology manager who was known for his resourcefulness and creativity, were asked to “deploy their antennas” in order to spot any opportunity to access the missing competencies. A few months later, the technology manager met by chance a technician specialized in the repair of immersed rotor pumps, who manifested a strong desire to set up a workshop and start producing rotor pumps. The two men had very similar views on the evolution of the technology and market and their affinities persuaded them to become partners. They rapidly went to present their project to Teemo’s owner-manager. Somewhat surprised by this turn of event, the owner-manager proposed them a number of arrangements in which Teemo would

continue to play a leading role, till he finally realized he had to accept their conditions. As he puts it: “I wanted more than 15 % of the company but I did not want to risk being excluded from the project (...)” Apart from this small financial participation, the two companies were tied by a strong commercial and technical assistance partnership since Teemo distributed and serviced the products of “Optix”, which also took advantage of the well-known Teemo brand.

In spite of his initial fears, the owner-manager of Teemo now judges very positively the whole process. In less than five years, the two entrepreneurs were capable of appropriating a complex technology, mastered by only three companies in the world. Optix is now the French leader on this growing and attractive niche. Such a fast development would not have been possible had the entrepreneurs been regular employees. The owner-manager claims that they would have been less motivated and daring in a company that, over the years, has become a little sleepy. The spin-off process has been a means to overcome the rigidity and prudence that characterizes Teemo’s culture and limits its innovation potential. This view is shared by the entrepreneurs who assert that they would never have gone as far had they been employees: “ (...) every time the technology was not working well, we spent long hours trying to find a solution instead of giving up (...) It is hard to imagine the same dedication from a regular employee (...)”.

Though it led to the loss of a valuable manager, the Optix spin-off enabled Teemo to access – at a relatively low cost and in little time – a technology well beyond its reach but critical for the balance of its business portfolio and long term survival. It has contributed to improve both its sales and margins.

- *The Mecanix → Beka Case: Creating a top level supplier/partner*

Mecanix is a small firm, which develops, produces and sells, mainly in France, complex mechanical parts. A few years ago, the owner-manager of Mecanix decided to outsource the machining shop of his production plant. He hoped with this move to improve productivity, gain space and facilitate the substitution of steel components with plastic ones. He proceeded with a call for tender. He soon discovered, however, that the available suppliers were not able to provide the level of quality achieved in-house. He also came to realize that his machining shop detained unique and valuable competencies and that it would be hard for his employees to find satisfactory outplacement solutions. Firing could not be avoided, along with its high human and financial costs.

The outsourcing project was therefore abandoned, till the shop supervisor came up with a take-over proposition. Skeptical at first, the owner-manager accepted to start the search process over again, inserting the shop supervisor in his short list of potential sub-contractors. Confronted with competitors, the shop supervisor deployed unexpected talents, showing both commitment and resourcefulness. Within three months, he performed a thorough market analysis proving the viability of his project, explained in details how he planned to improve productivity and promised to recruit all displaced employees. He managed to convince Mecanix’s owner-manager and “Beka” was created.

The take-over went on smoothly causing minimal disruption to Mecanix’s operations. The partnership is now giving fruit and the initial objectives of the owner-manager are about to be reached. Mecanix activities have remained stable, no firing has taken place and Beka is highly

productive. The purchasing manager of Mecanix emphasizes the value of their special relationship: "They know our products and our way of doing things very well. They often send us back our orders to tell us that some components can be simplified (...) you could not expect such advice from a regular supplier."

- *The Rally → Eva Case: Securing a key human resource in a tight labor market*

Rally is a medium-size company, which develops and publishes video games. Its activity requires a mix of artistic and technical competencies deployed in workgroups, which for the sake of creativity are granted a great deal of freedom. In 1998, Rally's owner-manager had to face the shocking news that a group of top employees was about to leave. They explained him that they needed even more autonomy and wanted to become entrepreneurs. These employees had developed the most successful video game in the company's history and were highly appreciated. Moreover, this event was taking place at a time when the labor market was very tight and competitors were out to recruit the best talents. Overcoming his dismay, Rally's owner-manager accepted to support the new venture with a small financial participation and a first game development contract. Shortly after "Eva" was created.

Right from the start, the new company experienced a steady growth of its personnel, turnover and margins. The various clients of Eva (and competitors of Rally) pushed the company to continuously improve the quality of its games, as well as the cost and speed of their development. Impressed by its performance, Rally's owner-manager expressed a desire to increase his financial participation in the spin-off. Later on, following the burst of the new economy bubble, Eva's director, with whom Rally's owner had maintained strong personal ties, accepted to return with Rally, on condition that he could preserve his autonomy. Since 2002, Eva has become a subsidiary of Rally but continues to function as an independent SME. Meanwhile, Rally's owner-manager has shut down his own game development department whose performance could not compare with that of Eva.

## **DISCUSSION**

Apart from the three basic strategic motives which each of them illustrate, the selected case studies also exemplify different top management postures vis-à-vis the spin-off.

The Teemo → Optix case, which shows how a spin-off can help rejuvenate the core competence of a company competing in a mature industry, is also a good example of a spin-off process in which the owner-manager plays a very active role right from the start. In fact we can say that he almost induces the process by focusing the attention of managers on the missing competencies and explicitly asking them to explore the full range of potential solutions. The spin-off constitutes an adequate, albeit surprising, solution to the problem he stated. When confronted with the unexpected part of the solution (the departure of his technology manager), the owner-manager vigorously attempts to take regain control but then realizes he has to proceed differently. He comes up with a win-win solution in which his strategic goals as well as the wishes of the entrepreneur are taken into account. Overall, the owner-manager takes a *proactive* posture with just the right dose of adaptiveness.

The Mecanix → Beka case, which shows how a spin-off can help resolve a make or buy dilemma by allowing the emergence of a supplier/partner, exemplifies a part induced, part emergent spin-off process. Confronted with a totally unexpected event – the shop supervisor take-over proposition –, which can nonetheless constitute a potential solution to his problem, the owner-manager of Mecanix quickly regains control over the process and decides to test the resources and determination of his employee and future supplier. He then fully supports the spin-off thus reinforcing his privileged relations with the entrepreneur. The owner-manager of Mecanix takes successively an adaptive and a proactive posture.

The Rally → Eva case, which portrays a spin-off process used to secure key human resources, also exemplifies a completely emergent spin-off process, which initially constitutes both a major disruption and threat to the mother company. In the face of this potential catastrophe, the owner-manager of Rally chooses to support the choice of his most valued employees. He manages, in this way, to maintain excellent relations with them, a move that later will prove wise and rewarding. He adopts a purely adaptive posture: his approach is one of yielding to contrary forces while keeping all options open.

Turning now to the empirical evidence we have gathered, we have identified three managerial attitudes or competencies, which are at the root of SME owner-managers' ability to use spin-offs as strategic tools.

- *Encouraging and considering employees' strategic initiatives*

In all three cases, owner-managers demonstrate a distinct ability to encourage and integrate employees' contribution to the definition of the firm's strategic agenda. Their attitude clearly stimulates employees' creativity, who then come up with innovative ideas and propositions. Such an attitude is encouraged by the proximity and simplicity that characterize relations in small-size organizations. It is clear that the close and informal environment of SMEs does favor a high level of interaction and communication among managers, thereby enabling strategic initiatives to flourish and compete (Amabile, 1996; Woodman et al., 1993). On the contrary, in large *centralized* organizations, hierarchical distance and structural inertia tend to limit strategic initiatives to the very top level while in large, *polycentric* organizations, the multiple and contradictory messages sent by top managers tend to disorient employees and bridle initiative.

However, encouraging creative ideas and debate is not sufficient: top management must be able to transform valuable employee's initiatives into effective strategies. For this to happen, a high level of involvement is required.

- *High level of involvement in the venturing process*

In all the cases presented, the owner-manager is personally and deeply involved in the venturing process. The three owner managers provide tangible support to entrepreneurs in the form of commercial and financial aids. They follow closely the entrepreneurs, testing them; encouraging them to go further and helping them refine their projects, in some case setting regular review meetings. Such a personalized support not only accelerates project development but also helps strategize the spin-off process by allowing the owner manager to 1) influence the final result, 2)

strengthen his ties with the entrepreneur and 3) legitimize the spin-off to the eyes of the rest of the company.

Such a close interaction between top and field managers can hardly be found in large firms for the reasons discussed previously whereas in SMEs, small size and proximity bring the strategic and operational levels together. In this context, top management's direct involvement becomes natural and easy. The owner-manager's central position shortens communication lines and considerably reduces lead times. Top management support helps put the project on the fast track and on the top of the company's strategic agenda. Implementation is made easier by the simple structure and informal procedures prevailing in SMEs. However, in order to ensure a quick launch another ingredient is required: an in-depth knowledge of the entrepreneur and the entrepreneurial process.

- *In-depth knowledge of the entrepreneur and the entrepreneurial process*

In the cases presented, all the owner-managers were very knowledgeable about their employees and about the entrepreneurial process, having founded or significantly developed a business themselves. Knowing well the would-be entrepreneurs enables the owner-managers to better assess their chances of success but also their capacity to work together later on. Being entrepreneurs themselves, the owner managers are in a better position when it comes to advise and support their employees concerning critical aspects of the entrepreneurial process.

Similarly to our previous arguments, this competence is less likely to be found in large firms than in SMEs where proximity and informality facilitate exchange and familiarity. Moreover, we could expect members of a SME to have greater "exposure" to entrepreneurial contexts, thereby to be more competent in the appreciation of entrepreneurial projects.

The attitudes and competencies we have just reviewed are required in order to "strategize spin-offs" i.e., to ensure that spin-offs *significantly contribute to the competitive advantage and performance potential of the mother company via the redefinition of its domain, boundaries and network of alliances*. These attitudes and competencies belong to individuals but the simple processes and structures, the actors' proximity and the clear leadership of SMEs definitely facilitate to their unfolding and affirmation.

In synthesis, we found that:

- In the context of SMEs, spin-offs generally contribute positively to the "mother" company's competitive advantage and performance potential: they constitute strategic tools;
- In their attempt to diversify their portfolio, find a reliable supplier or secure a key human resource, owner-managers of SMEs are able to turn an initially disrupting or threatening event – an impending spin-off – into an opportunity, and this by displaying a range of postures;
- This strategic ability relies on three key managerial attitudes and competencies: encouraging and integrating individual initiatives; strong personal involvement in the spin-off process and in depth knowledge of the entrepreneur and the entrepreneurial process;

- A strong link between these managerial attitudes and competencies and the SME context, characterized by organizational flexibility, actors' proximity and centrality of the owner-manager can be established.

## CONCLUSION

Up to now, spin-offs have never been studied in the context of SMEs (Carrier, 1996). Our study has established that spin-offs could be effective answers to some of the strategic issues facing SMEs such as diversifying, outsourcing and retaining key human resources. However, our study has not enabled us to ascertain if these benefits were long lasting. It would be important to establish whether this is the case and what parameters most influence the longevity of the "mother" company/spin-off relations: to answer these questions, a longitudinal study of these relations would be required.

Our study also reveals that SMEs are particularly good at making the most out of spin-offs. However, the determinants of this capacity need to be further explored and understood in order to determine whether large firms can built up such capability and how. If, as we suggested, this capability depends on attitudes and competencies which themselves depend on organizational characteristics such as flexibility, simplicity, proximity and centralized decision-making, quantitative research could aim at establishing beyond doubt their influence.

## ABSTRACT

This paper investigates a useful way to answer three fundamental questions about a cluster: (1) Under what conditions will a potential entrepreneur spin off from an incumbent firm? (2) Under what conditions could a cluster be created by entrepreneurial firms? (3) Are those conditions different depending on the types of industries/clusters? In order to address these issues, a three stage game between an incumbent firm and an entrepreneurial firm was constructed and analyzed. Basically, a potential entrepreneur will spin off from the incumbent firm if market size ( $M$ ) is large enough and entry cost ( $F$ ) is low enough. In the case of an industry producing complements with Firm I's products, Firm E will always spin off from it under those conditions. However, Firm I will always try to deter Firm E's entry by buying out Firm E when they are producing perfect substitutes. If an entrepreneurial firm has decided to spin off from an incumbent firm, its choosing to locate near a cluster would maximize its profit under certain conditions based on the comparison between the increase of congestion cost and the decrease of marginal production cost. The spin-off of the entrepreneur to start a new firm is efficient in the case of an industry producing differentiated products (imperfect complements and substitutes), but inefficient in the case of an industry producing perfect substitutes.

## I. INTRODUCTION

When you think of the Silicon Valley in California or Route 128 in Massachusetts, what is the most noticeable characteristic of those areas? It would be the clustering of firms. Although a lot of firms have already existed there for a long time – especially firms in the same industry, recently the tendency has been for them to concentrate in those areas even more quickly. Why have a lot of business firms been motivated to continue clustering in those areas? The answer to that question is very simple: because business firms in a cluster get spillover benefits from clusters and, thereby, maximize profits.

This paper investigates a purely “theoretical framework” in order to answer the next three fundamental questions about a cluster based on the assumption of profit maximization: (1) Under what conditions will a potential entrepreneur spin off from an incumbent firm? (2) Under what conditions could a cluster be created by entrepreneurial firms? (3) Are those conditions different depending on the types of industries/clusters? These three fundamental questions have not been answered in a theoretical framework, especially by using Game Theory. Thus, this paper could

be a useful way to address those issues, and help to fill the knowledge gap in the entrepreneurship literature. In section II of this study, three models of clusters to be analyzed in this paper will be described in detail. Then, in section III, solutions to and implications from our three models, including the conditions of an entrepreneurial firm's spin-off and location choice, will be discussed and suggested. In the conclusion, some of the limitations of this paper and possible research topics in the future will be discussed.

## II. THE MODELS

Our models in this paper can be thought of as a three stage game between an incumbent firm and an entrepreneurial firm, both of which try to maximize their profits through the location choice. In the first stage, a potential entrepreneur decides whether to spin off from the incumbent firm and enter the market with his own entrepreneurial firm. In the second stage, the entrepreneurial firm selects a location in which to operate, given that the incumbent firm's location is fixed. Then in the third stage, each firm names a quantity for its product simultaneously.

-----  
Insert Figure 1 about here  
-----

In order to incorporate different context of different industries, three models of industries/clusters will be categorized. The first case of clusters is the one created by regional specialties, the typical example of which is the Third Italy in Italy focusing on textile/clothing/leather industries. With "coopitition" of firms, the synthesis of cooperation and competition, both tradition and skill by regional specialties could have been maintained well in that cluster. Therefore, firms in the Third Italy have been said to produce almost homogeneous products which are perfect substitutes for each other and compete in a same market. On the other hand, the second case of clusters is the one by large company, for example Toyota City in Japan, which is famous for automobile industry. If a potential entrepreneur spins off from the incumbent automobile-making company, he/she doesn't produce a vehicle and compete in a same market with the incumbent. Rather, he/she usually produces a particular part of a car, which is a complement to the incumbent's vehicle. Therefore, one large company constitutes a hub of networks with its car-parts suppliers in that cluster, just like the case of Toyota City in Japan. The last case of clusters is the one created by university and research institutes. Bio-clusters in San Diego or Silicon Valley of IT industry might be good examples of this kind of cluster, in which the role of R&D development and technological innovations of firms have been most important in this cluster. Firms with science-based technology in high technology industries produce a lot of differentiated products which are imperfect substitutes with each other and compete in a same market.

Basically we will assume that there are two firms – Firm I (an incumbent firm) and Firm E (an entrepreneurial firm) – who are supposed to be located on a linear space of length  $l$ . If a potential entrepreneur decides to stay in the incumbent firm, then he can get a remuneration of  $B$  from the incumbent firm as compensation, which will be determined endogenously in our models.

Firm I is located at  $a = l / 2$  (which is fixed, because it already exists in that market) from the left extreme point of the linear space, and produces  $q_I$  of its product at  $c(q_I)$  and sells them at  $p_I$  per unit. Because we have only two firms in our model, we will assume that a cluster is composed of one incumbent firm for simplicity. If it is then shown that an entrepreneurial firm has a tendency to locate as close as possible to that incumbent firm, the implication will be that the cluster will expand progressively in the future. Firm E is located at  $b$  from the right extreme point of the linear space, and produces  $q_E$  of its product at  $c(q_E)$  and sells them at  $p_E$  per unit.

-----  
 Insert Figure 2 about here  
 -----

In the case of Model I: the Third Italy, market size is assumed to be  $M$ , which does not depend on a geographic market space. Each firm is supposed to face with the same demand function  $P = M - Q$ , in which  $P = p_I = p_E$  and  $Q = q_I + q_E$ . Therefore, we are considering Cournot competition in this market, because if the price of one firm is lower than that of the other, then one firm will disappear in our model and it will be unnecessary for us to talk about the clustering of firms. We assume that there are spillover benefits from the clustering of two firms, which decrease the production cost of each firm. There are two kinds of production costs, entry cost in this market ( $F$ ) and marginal cost of production ( $c$ ). We assume that Firm I will have zero entry cost, because it has already been sunk in the past, and zero marginal cost of production for simplicity. Therefore, Firm E's cost function can be expressed as  $C(q_E) = F + \frac{cq_E}{(\frac{l}{2} + b)}$ , in which

spillover benefits decrease the total variable production cost of Firm E as the sum of distances  $a (= l / 2)$  and  $b$  from the extreme points of a linear space increases, because it implies that the two firms have come closer to each other. On the other hand, we assume that there is a per unit / per distance congestion cost from clustering ( $G$ ), which increases the production cost of each firm. Therefore, total congestion cost of each firm,  $G(q_I) = q_I G(\frac{l}{2} + b)$  and  $G(q_E) = q_E G(\frac{l}{2} + b)$ , will subtract its profit.

In the case of Model II: Toyota City in Japan, Firm E is supposed to produce a particular part of Firm I's vehicle, which is a complement with the incumbent's product. Therefore, each firm is supposed to be faced with the demand function of differentiated product,  $q_I = M - 2p_I - p_E$  and  $q_E = M - 2p_E - p_I$ , respectively. Other assumptions on spillover benefits and congestion costs from clustering will be exactly same with those in Model I: the Third Italy.

In the case of Model III: Bio-clusters in San Diego, Firm E is supposed to produce a lot of differentiated products, which are imperfect substitutes for each other, based on the science-based technology. Therefore, each firm is supposed to be faced with the demand function of differentiated product,  $q_I = M - 2p_I + p_E$  and  $q_E = M - 2p_E + p_I$ , respectively. Since R&D investment and spillover play an important role in this cluster, we assume that the R&D investment by both firms ( $R > 1$ ) will decrease the total variable production cost of Firm E further than in the case of Model II: Toyota City in Japan. Therefore, Firm E's cost function can be expressed as  $C(q_E) = F + \frac{cq_E}{R(\frac{l}{2} + b)}$ . Other assumptions on congestion costs from clustering are exactly same as before.

### III. RESULTS AND DISCUSSION

We can find the equilibrium in this three stage game by applying a backward induction method. The main results from our 3 models used in this analysis and certain conditions under which a potential entrepreneur spins off from and locates close to the incumbent firm are summarized in < Table 1 >.

-----  
 Insert Table 1 about here  
 -----

We can get some interesting implications on an entrepreneurial firm's spin-off and location choice in a cluster, depending on the different types of industries considered in this analysis. First, a potential entrepreneur in the Third Italy, in which perfect substitutes are produced based on homogeneous products, will always stay in Firm I if congestion cost is low enough. We can anticipate that the only case of Firm E's entry in this market will be when entry cost ( $F$ ) is large enough and subsidized by others, for example, a local government or manufacturers association in that area.

Secondly, in the case of Toyota City in Japan, where complements are produced by both Firm I and Firm E, a potential entrepreneur will always spin off from and locate close to Firm I if the market size is large enough and entry cost and congestion cost are low enough. In other words, Firm I would not try to buy out Firm E's entry in this market, because Firm E's spin-off producing complements is advantageous to Firm I's profit.

Third, a potential entrepreneur in Bio-clusters in San Diego, in which imperfect substitutes are produced with differentiated science-based technology, will spin off from and locate close to Firm I if market size is large enough and entry cost and congestion cost are low enough.

Fourth, regarding the location choice of Firm E, it will compare the increase of congestion cost with the decrease of marginal production cost when it chooses its location. We should note that

$$G = \frac{\partial G(q_E)}{\partial q_E \partial b}$$

is the increase of congestion cost per quantity per unit distance, and

$$\frac{c}{(\frac{1}{2} + b)^2} = - \frac{\partial C(q_E)}{\partial q_E \partial b}$$

is the decrease of marginal production cost per quantity per unit

distance. We can see from < Table 1 > that a different type of industry has a different condition of Firm E's location choice close to the incumbent firm. In the case of industry producing complements, Firm E's location choice close to Firm I will be much easier than in other cases. Whereas Firm E's location choice close to Firm I will be much harder than in other cases in the case of industry producing perfect substitutes, because of increased competition and eventually increased congestion cost.

Fifth, regarding the spin-off choice of Firm E producing complements with Firm I's products, it will always spin off from Firm I if market size is large enough and entry cost is low enough as we have seen before. In the case of industry producing perfect substitutes, Firm I will always try to deter Firm E's entry by paying  $B$  to and buying out Firm E. In other cases, Firm E will spin

off from Firm I if market size is large enough and entry cost is low enough. That will be intensified in the case of industry producing imperfect substitutes with large level of R&D spillover.

Last, we can think about the next question; in each case, is the spin-off of the entrepreneur to start a new firm efficient or not? We can compare the monopoly profit by only the Firm I with the sum of duopoly profits by Firm I and Firm E in this market. Industry profits in each case are summarized in < Tabel 2 >.

-----  
Insert Table 2 about here  
-----

As we can see in < Table 2 >, the detailed result will be sensitive to the specification of parameters in our models. Therefore, we can use a numerical example with specified parameters, which satisfies every condition derived in our models, to get a tentative answer to the question above. With the numerical example of  $l = 10$ ,  $a = l / 2 = 5$ ,  $b = 4$ ,  $M = 100$ ,  $F = 600$ ,  $c = 10$ ,  $G = 0.05$ , and  $R = 2$ , we can get solutions to each stage in each model, which are summarized in < Table 3 >. Therefore, we can see that monopoly will realize larger industry profit than duopoly in the case of industry producing perfect substitutes because duopolists are supposed to compete fiercely in quantity in the same market, whereas duopoly will realize larger industry profit than monopoly in the case of industry producing differentiated products (complements and imperfect substitutes) because duopolists can make best use of differentiation of consumers in those differentiated markets.

#### IV. CONCLUSION

A three stage game between an incumbent firm and an entrepreneurial firm was constructed and analyzed in order to answer three fundamental questions about a cluster: (1) Under what conditions will a potential entrepreneur spin off from an incumbent firm? (2) Under what conditions could a cluster be created by entrepreneurial firms? (3) Are those conditions different depending on the types of industries/clusters? Basically, a potential entrepreneur will spin off from the incumbent firm if market size ( $M$ ) is large enough and entry cost ( $F$ ) is low enough. In the case of industry producing complements with Firm I's products, Firm E will always spin off from it under those conditions. However, Firm I will always try to deter Firm E's entry by buying out Firm E when they are producing perfect substitutes. Regarding the location choice of Firm E, if an entrepreneurial firm has decided to spin off from an incumbent firm, its choosing to locate near a cluster would maximize its profit under certain conditions based on the comparison between the increase of congestion cost and the decrease of marginal production cost, which are different depending on the type of industry. The spin-off of the entrepreneur to start a new firm is efficient in the case of industry producing differentiated products (complements and imperfect substitutes), but inefficient in the case of industry producing perfect substitutes.

This paper has limitations that can be the basis for some useful future research. First, since our models in this paper are purely “theoretical” and “algebraic” frameworks for an entrepreneurial firm’s spin-off and location choice analyzed by Game Theory, the main results suggested have not yet been tested with real data. Moreover, there was no discussion about what would be the most appropriate variables to measure the parameters of our models. Empirical research could be designed in that direction in order to test the validity of the main results suggested in this paper. Second, our model implicitly assumes that there is only one period of time in which each firm can realize a profit. Although this assumption is made mainly for the sake of simplicity of analysis, we can think about the possibility of using the N-period finite model or the infinite model in the real business world. Therefore, there could be future research that would incorporate a long time horizon and a discounting factor of time preference into our models. Third, our models in this paper assume that there are only two players in this game, Firm I and Firm E. However, we can expect that there might be somewhat different results in the case of many incumbents, many entrants, or both of them. Three additional cases can be considered in the future; < Case 1 > Many incumbent firms & One potential entrepreneur, < Case 2 > One incumbent firm & Many potential entrepreneurs, and < Case 3 > Many incumbent firms & Many potential entrepreneurs. Lastly, our analysis in this paper was confined to the case of complete information. However, we can think about the case of incomplete information, in which information about some of parameters in our models is not known to both an incumbent firm and an entrepreneurial firm. We can assume that an entrepreneurial firm has complete information of its own production cost, but an incumbent firm has to predict what type of production cost an entrepreneurial firm has on the basis of its subjective probability and the distribution of an entrepreneurial firm’s production cost. These limitations of this paper will be our next destination in future research.

### **Abstract**

To search for a common ground, may or may not exist, between entrepreneurship theories, policies, and realities, an on-going national survey was designed and implemented to explore perceptions of male and female entrepreneurs in new venture formation. Sample information showed discrepancies between male and female entrepreneurs in their expectations and learning experiences associated with personal goals, financial achievement, and family life. Heterogeneities also exist among women entrepreneurs in manufacturing industry and retail/service industry corresponding to their expectations and learning experiences of new venture formation. Current policies may serve some needs for women entrepreneurs. More segregated and targeted services and assistance could be provided to women who would be interested in starting new businesses, or who failed in the new venture formation process.

### **Introduction**

Among the fascinating movements in the formation of the new businesses, there seems to be a more rapid growth trend for women to embark on entrepreneurial activities than male entrepreneurs according to a recent report by the National Women's Business Council (NWBC, 2005). Statistics showed that the number of women- and equally-owned firms grew by 17 percent, compared to 9 percent among all privately-held firms between 1997 and 2004 (NWBC, 2005). The number of majority-owned, privately-held women-owned businesses grew by 23 percent during the same period (NWBC, 2005). The growth rates in employment among women-owned firms with 100 or more employees increased by 44 percent between 1997 and 2000, and the number of women-owned firms with \$1 million or more in revenue grew by 32 percent in the same period – both nearly twice the rate of all comparably sized firms (WNBC, 2005).

The new estimates showed an average of 424 new women-owned firms were started every day, equivalent to 775,000 start-ups per year and accounting for fully 55 percent of new firm start-ups (WNBC, 2005). While there is an increasing amount of research on entrepreneurs and/or the entrepreneurial environment, there has been limited information that differentiates decisions or behaviors between female entrepreneurs and their male counterparts. Does this new generation of women business owners have the traits or psychological characteristics described in previous theories? Do women entrepreneurs develop their ideas into businesses following the same patterns as described by entrepreneurship theories? Do women entrepreneurs present similar expectations in business decisions, personal satisfaction, and family benefits compared to their male counterparts?

It is important to distinguish the studies of entrepreneurship from other economic theories given different characteristics and cultural background of men and women, due to the complexity of understanding interactions between gender issues and entrepreneurship. Some researchers have started to realize that differentiating factors may separate female entrepreneurs from male entrepreneurs such as accessing educational opportunities, accessing resources to create and develop ideas, identifying sustainable ideas, finding supportive networks, and being recognized as equally competitive in the markets. More policies have also tended to facilitate capital access, technical assistance, mentoring assistance and equalities in bidding on government contracts.

This paper presents the results of an on-going study to explore three research questions: (1) Are there any differences between female and male entrepreneurs in their characteristics, personal traits, business decisions, and personal assessment of impacts of new venture creation on quality of life, given a set of hypotheses described in previous literature? (2) Are there any differences among women entrepreneurs in different type of industries in their characteristics, personal traits, business decisions, and personal assessment of impact of new venture creation on quality of life, given a set of hypotheses described in previous literature? (3) Do current policies designed to support entrepreneurial activities among women make any differences for women entrepreneurs?

The findings of our study will benefit other professionals and practitioners who work closely with entrepreneurs and their families to understand the common ground, if any, between entrepreneurship theories, policies, and realities. Several assumptions need to be introduced in this study: (1) the businesses in this study are “new ventures” that have high potential for job creation and wealth accumulation from the societal perspective, not “micro-businesses” that are generally defined as small scale operations. (2) Wealth creation, sustainable profitability, personal satisfaction, and family welfare are simultaneously valued by entrepreneurs, not necessarily in any particular rank or with equal importance. (3) Both “entrepreneurial individuals” and the “environment in which entrepreneurs have been found” contribute to the success or failure of the new venture creation.

Since this is an exploratory study, it is not the authors’ intention to generalize the results of this study. The results presented in this article examine a set of the variables that might lead to some new discovery in entrepreneurship field. Through exploration of the variables that might influence entrepreneurs’ perceptions of business decisions and family relationships, this article hopes to present some outcomes that would be of interest to other researchers and to further develop entrepreneurship theories and testable hypotheses corresponding to the theories. This approach was inspired by the Grounded Theory to develop any theory inductively from a corpus of data using well-structured constraints and frameworks to ensure the robust ability of the theory when tested by new data (Galser & Strauss, 1967).

### **Overview of Research and Theory**

Two approaches have emerged in recent years that examine entrepreneurial phenomenon, which also represent the division among scholars in entrepreneurship study. One group of researchers had sought to explain or identify those members in our society who could be considered “entrepreneurial individuals”. These researchers have discussed entrepreneurship as a locus of human attributes, characteristics, traits, or psychology that differentiated entrepreneurs from the rest of the society (Shane,

2003; Carland & Carland, 2000; Liang & Dunn, 2002). Another group of researchers sought to explain entrepreneurship by examining the environment where entrepreneurs have been found (Shane, 2003). This school of thought attempted to identify situations in which entrepreneurial activities were more likely to occur. These activities usually relate to new firm formation or new expansions/renovations of existing firms. Some key variables examined in previous literature included variations in industry dynamics, organizations, technology, market structure, and other exogenous economic factors (Shane, 2003).

Differences between female and male entrepreneurs do exist in business and industry choices, financing strategies, growth patterns, and governance structures of ventures (Green, Hart, Gatewood, Brush & Carter, 2003). Scholars continue to challenge Gertrude Stein's comment, "An entrepreneur is an entrepreneur," by looking into more details of the separation between female and male entrepreneurs. While exploratory studies have identified similarities between female and male entrepreneurs, there is limited information to understand the differences. There seems to be a growing interest in examining if female and male entrepreneurs differ in terms of objectives, motivations, preparation, organization, strategic orientation, and access to resources (Greene, Hart, Gatewood, Brush, & Carter, 2003). A paper containing a comprehensive literature review (Greene, Hart, Gatewood, Brush, & Carter, 2003) of women entrepreneurship indicated that a small, yet increasing, proportion of published journal articles discussed women entrepreneurs. In earlier studies such as in the 1980s, smaller sample and interview information focused more on "women entrepreneurs". Some popular questions for investigators included what women entrepreneurs were like (traits, demographics, personal characteristics), why women entrepreneurs started businesses (motivations), and how women managed to start businesses (psychological measures). Some scholars tried to define "average women entrepreneurs" by comparing with their male counterparts. Earlier studies discovered that women were more inclined to start new businesses in traditionally female industries (retail, hospitality, service). Some researchers discovered challenges, barriers, and constraints for women to start businesses in access to financial support, generating capital, and general negative beliefs about women succeeding in business world.

These earlier studies drew attention to the fact that there was a significant population of women entrepreneurs were starting a wide variety of new ventures, and women entrepreneurs somewhat differed from male entrepreneurs in personalities and decision-making strategies. Several government initiatives were since established to support women entrepreneurs, such as Community Reinvestment Act (CRA) and Small Business Investment Companies (Greene, Hart, Gatewood, Brush, & Carter, 2003).

Research themes emerging since the 1990s became broader than earlier trait theory or psychological theories. Newer studies on women entrepreneurs included growth and performance of new ventures, strategic choices, determinants of opportunities, financing, business outcomes, social network, international trade issues, education and skills, and movements of female's role in our society. New policies were also developed and implemented to assist women entrepreneurs from a broader perspective (Greene, Hart, Gatewood, Brush, & Carter, 2003). Babson College and London Business School initiated the Global Entrepreneurship Monitor (GEM) in 1999 to measure differences in the level of entrepreneurial activity between countries, probe for a systematic relationship between entrepreneurship and national economic growth, uncover factors that lead to higher level of entrepreneurship, and suggest policies that may enhance the national level of entrepreneurial activity. The GEM data has shown that the participation of women in entrepreneurship is significant in spite of national variations (Minniti & Arenius, 2003). Evidence has shown that adult women represented a readily available pool of potential

entrepreneurs that countries may leverage to improve their economies. Moreover, this potential existed among nations in various stages of development and with different demographic patterns and labor force conditions (Minniti & Arenius, 2003).

National Women's Business Council released 2004 annual report recently and summarized research results among women entrepreneurs across industries and ethnicity (NWBC, 2004). There is an on-going effort to promote, support, and educate women entrepreneurs by various private and government agencies. Several studies and outreach programs in the United States and around the globe have been supported by the NWBC such as the global Entrepreneurship Monitor (GEM) research program, State Economic Networks for Women Business Owners, The Legacy and the Future of Women Entrepreneurs, Trend in Women-Owned Employer Establishments, Best Practices in Supporting Women's Entrepreneurship in the United States, Policy and Progress in Supporting the Growth of Women's Business Enterprise, Analyzing the Economics Impact of the Women's Business Center, Mentoring Web Cast Discussion Event, Accessing Government Markets and Women's Business Connection Conference Calls. Based on the research conducted in 2004 by the NWBC, several policy recommendations were proposed to the President, the U.S. Congress, and the U.S. Small Business Administration regarding challenges and barriers that women business owners still encounter such as access to capital, access to federal procurement markets, access to training and technical assistance, fact-based policy-making, and ongoing advocacy (NWBC, 2004).

To conclude, previous literature provided a broad discussion about women business owners from "entrepreneurial individualism" to "entrepreneurial environmentalism". There seems to be a gap between anecdotal information, theoretical framework, and policy implications. Do women entrepreneurs possess different expectations and learning experiences compared with male business owners given the variations in industries and personalities? Do women entrepreneurs in different businesses have the same expectations and learning experiences? Do current policies serve women entrepreneurs effectively? This study attempts to examine the above questions that have not been fully discussed in other literature.

### **Data**

A sequential probability sample of 1009 manufacturing and 1036 retail and service firms with fewer than 50 employees that had been in the database less than five years was drawn from the American Business Disc, Second Edition, 1999. This database has often been used by the Small Business Development Center to conduct impact studies. A questionnaire was developed, pre tested, and revised to collect the information needed for the study. The survey was designed for entrepreneurs only, and one business owner in each business or each household answered the questions. The answers reflected the owner's personal view regarding his/her personal perspectives for themselves, their spouse and children. None of the spouses or children was expected to answer the questions because (1) spouses and children might not live in the business address, and (2) there were technical difficulties and concerns to access spouses and children to collect their responses. Of the 1009 questionnaires mailed to manufacturer entrepreneurs, 258 were returned as not deliverable and of the 1036 questionnaires mailed to retail/service firm entrepreneurs, 158 were returned as undeliverable. One hundred thirty five retail questionnaires and 137 manufacture questionnaires were returned for a 15 percent retail and a 14 percent manufacture response rate.

Questions were separated into several sections. The first section related to personal and business demographics –

- When and how business was started.
- Business location (rural or urban areas).
- Entrepreneur's age, marital status, and education.
- Whether spouses and children worked in the business.
- Number of full-time and part-time employees.
- Annual sales of the business.
- Major sources of funds.

The second section of the questions involved “expectations of the new venture” –

- If sales were higher than expected.
- If profits were higher than expected.
- If starting the new venture was harder than expected.
- If starting the new venture took longer than expected.
- If entrepreneur's expectation was too optimistic.
- If spouses and children were enthusiastic before starting the new venture.
- If entrepreneur expected to be happier and financially better off before starting the new venture.
- If entrepreneur expected the new venture would improve family happiness and financial situation.

The third section of the questions provided an opportunity for entrepreneurs to express the learning experiences after starting and running the new ventures –

- Entrepreneurs were happier and better off financially.
- Family members were happier and financially better off.
- Entrepreneurs and family members had challenges in time management.
- Entrepreneurs revealed various effects of new venture creation on their marriages.
- If the entrepreneurs and family members would start another new venture again.

The last section of the questions was only responded by manufacturing business owners. This section asked the manufacturing entrepreneurs, both men and women, what they would do differently if they were to start another new venture. Options provided for entrepreneurs to choose from included –

- Change business location.
- Use more advertising.
- Define target market better.
- Get more cash before starting the new venture.
- Do more research before starting the new venture.
- Prepare a better business plan.
- Get more business training before starting.
- Not involve family members in the start-up process.

Since responses to the questions were collected by level choices or preferences, categorical data analysis is more appropriate. Two instruments were applied to test the differences in two categories (entrepreneur versus spouse): *Chi-square* test and *Gamma* test. *P*-values were calculated for both of the tests in all categories.

## Discussions of the Results

Results of the analysis were presented in three sections based on the questions. We separated the results into two categories – all entrepreneurs including men and women, and women entrepreneurs in manufacturing businesses and retail/service businesses. We would like to discover the differences, if any, between male and female entrepreneurs, and women entrepreneurs in two industries in their demographics, expectations, and learning experiences.

### Personal and Business Demographics

Among all entrepreneurs, 49 percent of 78 women and 36 percent of 172 men started the businesses less than five years ago. Only 5 percent of 78 women started businesses more than 11 years ago, which was lower than their male counterparts (15 percent of 172 men). The years of starting up were statistically significantly different between women and men at 10 percent significance level. Fifty-four percent of 79 women businesses were in rural areas, while 38 percent of 177 male-owned businesses were located in rural areas. The responses of business location were also statistically significantly different at 10 percent between women and men. Fifty-nine percent of 80 women business owners were married with children, and 79 percent of 179 male business owners were married with children. A slightly higher percent of women business owners (18 percent) were single parents than their male counterparts (8 percent). Marital situation also showed 10 percent statistical significance between men and women. Sixty percent of both female and male entrepreneurs had spouses working in the businesses either full time or part time. More women entrepreneurs (37 percent of 57) had children working part time in the business compared to the male business owners (24 percent of 152). Most of the entrepreneurs, both men and women, did not involve children in the business (60 percent). Interestingly a significantly majority of women business owners (91 percent of 68) had less than 5 full time employees, and this proportion was almost twice as high as their male counterparts (48 percent of 172). The age distribution of women business owners were about the same as men with 96 percent to 99 percent of them older than 30 years of age. Thirty-nine percent of the 80 women entrepreneurs used personal savings, while 48 percent of 177 male entrepreneurs used personal savings to start the new venture. A slightly higher proportion of women entrepreneurs used family savings (18 percent of 80) and loan (36 percent of 80) to start the new venture, compared to male entrepreneurs using family savings (7 percent of 177) and loan (34 percent of 177). Another noticeable result (statistically significant at 1 percent level) was revealed in the annual sales. Eighty percent of 80 women business owners had annual sales less than \$500,000 compared to 52 percent of 180 male entrepreneurs.

When comparing women business owners in two industries, 52 percent of 25 manufacturing women entrepreneurs and 47 percent of 53 retail/service women entrepreneurs started businesses less than five years ago. The majority of the women, 40 percent of 25 in manufacturing and 50 percent of 53 in retail/service started businesses between 6 to 15 years. Fifty-two percent of 27 manufacturing women entrepreneurs were located in rural areas, versus 56 percent of retail/service women entrepreneurs. The majority women business owners were married with children in both industries (67 percent of 27 in manufacturing and 56 percent of 53 in retail/service). Spouses did not work for 52 percent of 21 manufacturing women entrepreneurs, while 67 percent of 39 retail/service women entrepreneurs had their spouses working either part time or full time in the business. The majority of women did not have their children working in the business (63 percent to 53 percent). A very high percentage of retail/service women business owners had less than five full time employees (96 percent of 49), compared with

manufacturing women business owners (79 percent of 19). This was the only variable indicated 10 percent statistical significance. More manufacturing women entrepreneurs used personal savings to start the new venture (44 percent of 27), while more retail/service women entrepreneurs used loan to start the new venture (43 percent of 53). Most of the women entrepreneurs, in both manufacturing (81 percent of 27) and retail/service (83 percent of 53) businesses, reported less than \$500,000 in annual sales.

### **Expectations of New Venture Creation**

A significant proportion of all entrepreneurs, men or women, went into businesses because they would like to be in control (over 50 percent for both men and women). A significant proportion of women entrepreneurs (81 percent of 63 women), compared to 71 percent of 157 men, believed that their spouses were enthusiastic before starting the new venture. Seventy-three percent of 52 women and 67 percent of 140 men believed their children were enthusiastic before creating the new venture. Approximately 70 percent of all entrepreneurs expected the family (including themselves and family members) to be happier before starting the new venture. A slightly higher proportion of women entrepreneurs (81 percent of 75 women) versus men (76 percent of 177 men) expected the new venture to improve their financial situations. Seventy percent of all entrepreneurs, men and women, expected the new venture to improve family financial situation.

Expectations among women entrepreneurs were not uniformly distributed in different industries. A higher percentage of women entrepreneurs in retail/service businesses expected their spouses to be enthusiastic (87 percent of 39 women) compared to 71 percent of 24 women in manufacturing businesses. Statistically significant at 1 percent level, more women business owners in retail/service industry (89 percent of 28 women) believed that their children were enthusiastic about the new venture before starting, compared to 54 percent of 24 women manufacturers in our sample. A slightly higher percentage of women in retail/service businesses (71 percent of 51 women) expected to be happier before the new venture formation, compared with 65 percent of 23 women manufacturers. However a higher proportion of women manufacturers (71 percent of 21 women) expected their family member to be happier before the new venture formation, compared to 63 percent of 46 women in retail/service businesses. Personal financial achievement seemed to a major objective for 88 percent of 25 women manufacturers and 78 percent of 50 women entrepreneurs in retail/service businesses. Sixty-seven percent of 24 women manufacturers and 71 percent of 44 women business owners in retail/service businesses expected their family members to be happier as a result of the new venture.

### **Perceptions of Reality**

A significant proportion of all entrepreneurs (82 percent of 79 women and 81 percent of 176 men) in our sample revealed that their income was good before starting the new venture. Approximately sixty percent of all entrepreneurs, men or women, in our sample agreed that starting the new venture took longer than expected and that the process was harder than expected. Only thirty-nine percent of the 80 women entrepreneurs and 42 percent of 178 male entrepreneurs agreed that sales were higher than expected. Even fewer women entrepreneurs (22 percent of 78) and male entrepreneurs (28 percent of 178) indicated that profits were higher than expected. Interestingly, a significant proportion of men believed that their business was up and running well (89 percent of 180) compare to women (83 percent of 78). Fifty-three percent of 77 women and 44 percent of 178 men agreed that their expectations of the

new venture were too optimistic. A statistically significantly (at 1 percent level) smaller proportion of women entrepreneurs (60 percent of 79 women) reported that they were actually happier after starting the new venture, compared to 85 percent of 178 male entrepreneurs in our sample. Another statistical significant difference showed in the evaluation of family happiness after starting the new venture (at 1 percent significant level). Only forty-one percent of the 64 women entrepreneurs agreed that their family members were happier after starting the business, versus 69 percent of 162 male entrepreneurs. Women and men seemed to have quite different assessments of the financial improvement in new venture formation (statistically significantly different at 1 percent). Only 35 percent of 74 women believed that their own financial situation was improved due to the new venture, while 65 percent of 176 men believed that their own financial situation was improved. Forty percent of 61 women entrepreneurs indicated that the family financial situation was improved after starting the new venture, and 59 percent of 158 men indicated the new venture actually improved their family financial situation.

Women in different industries definitely revealed diverse perceptions of reality after new venture creation. Almost twice as many as women manufacturers (89 percent of 27 women) believed that sales were lower than expected, compare to 47 percent of 53 women in retail/service businesses. Only eight percent of 25 women manufacturers agreed that the profits were higher than expected, compared to 28 percent of 53 women businesses owners in retail/service industry. There were statistically significant differences in women entrepreneurs' perceptions of sales (significant at 1 percent) and profits (significant at 5 percent) in different industries. More women in retail/service businesses believed that their businesses were up and running well (85 percent of 53 women) compared to 67 percent of 27 women entrepreneurs, and this result was significant at 10 percent level. A majority women entrepreneurs (52 percent of 27 women manufacturers, and 70 percent of 53 women retail/service owners) revealed that starting the new venture was harder than they expected. Almost 63 percent of women entrepreneurs, either in manufacturing or retail/service businesses, believed that starting the new venture took longer than they expected. Half of the women entrepreneurs in our sample, either in manufacturing or retail/service businesses, believed that their expectations on the new venture were too optimistic. An interesting phenomenon existed in women's perceptions on financial improvements. Eighty to eighty-three percent of women entrepreneurs in both manufacturing and retail/service businesses revealed that their income was good before the new venture formation. Only 29 percent of 24 women manufacturers and 38 percent of 74 women in retail/service businesses admitted that their personal financial situation was improved after starting the new venture. Almost two-thirds of women entrepreneurs in both manufacturing and retail/service businesses agreed that the new venture actually improved their family financial situations.

### **Impacts of New Venture Creation on Quality of Life**

Statistically significant at 1 percent level, more male entrepreneurs (85 percent of 178 men) agreed that they were actually happier after forming the new venture. Only 60 percent of the 79 women shared the same feeling, though. Also a significant (at 1 percent significance level) proportion of men (69 percent of 162 men) agreed that their family members were actually happier after starting the new venture, compared to 41 percent of 64 women. Sixty-eight percent of 78 women entrepreneurs and 65 percent of 173 male entrepreneurs agreed that they did not have enough time for themselves after starting the new venture. More women entrepreneurs (55 percent of 62 women) revealed that they had not been able to spend as much time with their spouses, compared to 48 percent of 161 male entrepreneurs. Similarly, more women entrepreneurs (58 percent of 55 women) responded that they were not able to

spend enough time with their children, compared to 46 percent of 166 male entrepreneurs. Statistically significant at 10 percent level, more male entrepreneurs (56 percent of 163) believed that new venture creation had no effect on their marriage, compared to 42 percent of 64 women entrepreneurs. Some negative consequences of the new venture formation influencing marriage according to our male sample were estranged (4 percent), separated (2 percent), and divorced (5 percent). Some negative impacts of new venture formation according to female entrepreneurs included estranged (2 percent), separated (3 percent), and divorced (3 percent). Interestingly, 14 percent of the male entrepreneurs and 11 percent of the female entrepreneurs agreed that the new venture creation actually improved their marriage relationships. Significantly a higher proportion of male entrepreneurs (91 percent of 170) agreed that they would start another new venture again, and their family members would support them. Women entrepreneurs, however, were not as inclined to start another new venture again. Only 75 percent of 72 women entrepreneurs in our sample would be willing to start another new venture again, and their family members would support them again.

There were discrepancies in the perceptions of “quality of life” among women entrepreneurs in different industries after starting the new venture. A significantly higher proportion (at 5 percent level) of women businesses owners in retail/service industries (76 percent of 53) revealed that they had no time for themselves after starting the new venture, compared to 53 percent of 25 women manufacturers. Also a higher percentage of women in retail/service businesses (62 percent of 39) admitted that they did not spend enough time with their spouses, compared to 44 percent of 23 women manufacturers. Almost 60 percent of all women entrepreneurs, either in manufacturing or retail/service industry, admitted that they did not spend enough time with their children due to new venture creation. More women business owners in retail/service industry (63 percent of 41) agreed that new venture creation had some impacts on their marriages, compared to 48 percent of 23 women manufacturers. Although most of the impacts of new venture creation on their marriages were negative (estranged, separated, or divorced), 17 percent of 24 women manufacturers and 8 percent of women in retail/service businesses believed that their marriage relationship was actually improved due to the new venture. A significantly higher proportion of women manufacturers (91 percent of 23) would be willing to start another new venture again, compared to 68 percent of 53 women in retail/service businesses. Interestingly, 76 percent of all women entrepreneurs (in either manufacturing or retail/service) believed that their family members would be supportive if they would start another new venture.

### **Changes of Strategies Corresponding to Learning**

Several questions were presented to manufacturing entrepreneurs only – what would you do differently if you were to start another new venture? Women and men seemed to have different perceptions. Among women entrepreneurs, 33 percent would like to have more cash and to define their market better; 30 percent would like to write a better business plan and to have more business training; and 26 percent would like to change their business locations and conduct more research. Forty percent of the male entrepreneurs would like to have more cash, 31 percent would like to prepare for a better business plan, and 27 percent of the men would not change anything compared to what they did before.

### **Conclusions and Policy Implications**

Some common themes of the study of entrepreneurship have involved understanding individual entrepreneurs or environment where entrepreneurs exist (Shane, 2002; Mitchell, Busenitz, Lant,

McDougall, Morse, & Smith, 2002). The individualization approach discussed entrepreneurial personalities, traits, cognitions, and how the entrepreneurial decisions related to individual psychology in new venture formation (Mitchell, Busenitz, Lant, McDougall, Morse, & Smith, 2002). To extend the understanding of how environment or exogenous economic factors influencing new venture formation, researchers studied the organizational transformations, industrial fluctuations, economic cycles, managerial transactions, and orientations of public policies that might or would open the window of opportunities for entrepreneurs (Carland & Carland, 2000). Most of this research developed conceptual frameworks based on some necessary, yet may not be sufficient, conditions to define entrepreneurship due to the diverse nature of the research topic (Shane, 2003). Various fragmentary outcomes of recent entrepreneurship studies have been generated by case studies, surveys, or collections of anecdotal sources such as Internet or observations. Are we trying too hard to find a robust one-size-fits-all model to explain entrepreneurship corresponding to the fluctuations in modern economy?

A mail survey was conducted with business owners in the United States. Sample entrepreneurs (both female and male in retail, service, and manufacturing industries) responded to a set of questions regarding their demographics, business profiles, expectations of business development and quality of life, realities of business development and quality of life, and learning experiences associated with business decisions and policies. The results of this exploratory study revealed some significant differences between female and male entrepreneurs in their characteristics, personal traits, and business decision process. Female and male entrepreneurs also have different perceptions of the impacts of new venture creation on their business performance, personal life, and family life. More interestingly, heterogeneities exist among female entrepreneurs in different industries regarding entrepreneurial decisions and personal and family welfare.

To summarize the results –

- Women entrepreneurs seemed to have less full time employees and less annual sales compared to male entrepreneurs. Other business profile and personal demographics were similar between male and female entrepreneurs in our sample.
- More male entrepreneurs were more optimistic about the new venture formation compared to female entrepreneurs, which related to their expectations in sales, profits, personal happiness, and family welfare.
- More male entrepreneurs had positive experiences in the new venture formation compared to female entrepreneurs, which reflected in their learning experiences associated with the reality.
- Women in different industries seemed to have similar personal and business profiles. The structures of the businesses and the nature of the businesses seemed to influence women's perceptions on expectations and learning experiences. Women in manufacturing businesses seemed to be more optimistic than women business owners in retail/service businesses. Yet women manufacturers also seemed to have a more conservative assessment of the new venture on their personal and family lives in their expectations. In reality, women manufacturers seemed to encounter less negativities and challenges in personal and family relationship, compared to women business owners in retail/service businesses.
- While current policies provide some support and assistance to women entrepreneurs, women business owners in our sample have mixed feelings and identified other areas that might need further research. The needs revealed by women entrepreneurs seemed to deviate from male entrepreneurs.

Another interesting observation derived from our study is the differences between current policies and what entrepreneurs really need. The National Women's Business Council (WNBC, 2004) had made some policy recommendations such as access to capital, access to federal procurement markets, access to training/technical assistance, fact-based policy-making, and ongoing advocacy. Women in our sample, however, proposed other things that they would like to pursue if they would start a new venture again. These women, operating in a much smaller scale compare to their male counterparts or other enterprises, revealed the needs of more cash (access to capital), the needs to prepare for a better business plan (access to training and education), and the needs to have more business training. They also indicated that they needed to learn how to conduct initial research that would assist them to identify a feasible location and an effective market segment.

Some policy implications from our exploratory study include –

- (1) The changes that entrepreneurs would make suggest that emphasis could be placed on making entrepreneurial education programs available for pre-venture entrepreneurs. These programs could include classes, mentoring, or advising services for entrepreneurs. Perhaps government lending programs could “strongly” suggest to potential borrowers that participation in such programs would be advisable, if not required, before loans are made or guaranteed. Such a policy could improve entrepreneurial performance and reduce the number entrepreneurs who have difficulties.
- (2) Technical assistance and training offered by Small Business Development Center and other agencies should go beyond “preparing for a loan package”. Research process and contents should be included in workshops, classes, or symposium to guide entrepreneurs how to conduct effective research on their market, location, trade partners, and economic variations. Updated research lists should be provided to entrepreneurs directly in these training events. Some entrepreneurs may not even know the existence of the webpage for various agencies unless someone tells them so.
- (3) There is a need to compile a comprehensive dataset to record entrepreneurs who succeed versus who fail in the new venture creation process. All studies, including ours, use a data set that include entrepreneurs in some kind of database or listings collected by private or public agencies. It will be ideal for training organizations or service providers to keep a record of those who participate in the training or information sessions, who continue to pursue the new venture opportunities, who actually create businesses, and who disappeared from the market after a certain period of time.
- (4) We need to access those women who never ask for assistance, assuming women have not been taught to be aggressive in seeking assistance.
- (5) There may be a need to train male counselors to work with women. Women have different learning style than men. Women also bear different societal responsibilities and roles compared to men, given cultural and conventional perspectives in our community. Male trainers and counselors need to understand women entrepreneurs' perceptions better, so that the programs or information will be delivered efficiently.
- (6) To serve women entrepreneurs better, there is a need to train more female trainers and counselors in the field. This could be accomplished using current mentoring system to recruit more female professionals to provide services to other women. While mentoring system connects women together, women also need to be trained and educated in a more aggressive manner before delivering programs to others.

Y. If you could start this business again, what would you do differently?

- Change business location.
- Use more advertising.
- Define target market better.
- Need more cash before starting the new venture.
- Need to conduct more research before starting the new venture.
- Prepare for a better business plan.
- Need more business training before starting.
- Do not involve family members in the start-up process.

Z. Are there other things that have happened as a result of starting your business that you can share with this research team? Your inputs will help others to better understand the process of starting the business.

# VALUES AND ENTREPRENEURIAL ATTITUDE AS PREDICTORS OF NASCENT ENTREPRENEUR INTENTIONS

Noel J. Lindsay<sup>1</sup>, Anton Jordaan, and Wendy A. Lindsay

Centre for the Development of Entrepreneurs  
University of South Australia

## ABSTRACT

This exploratory research examines the relationship between values, the entrepreneurial attitude of nascent entrepreneurs (individuals intending to establish new businesses), and their entrepreneurial intentions. This involved administering a questionnaire to 166 participants who were unemployed and who identified themselves as nascent entrepreneurs after a thorough screening process to ensure they intended starting businesses. Prior research has identified values/beliefs as influencing attitudes, attitudes as influencing intentions, and intentions ultimately influencing behavior. Surprisingly, in this research, only a weak relationship existed between the three List of Values dimensions (empathy, achievement, and hedonism) and entrepreneurial attitudes. Significant relationships, however, were identified between the dimensions underpinning entrepreneurial attitude orientation (EAO) and entrepreneurial intention. In addition, although a relationship existed between two of the values dimensions, empathy and hedonism, there was no significant relationship between the achievement values dimension and entrepreneurial intention. This was perplexing since it could be expected that there would be an achievement-entrepreneurial intention relationship for nascent entrepreneurs. Since attitudes are changeable and values are more likely to be stable over time, values may enhance the information provided by nascent entrepreneur EAO.

## INTRODUCTION

This exploratory research examines the relationship between values, the entrepreneurial attitude of nascent entrepreneurs, and their intentions. An attitude is the predisposition to respond in a generally favorable or unfavorable manner with respect to the object of the attitude (Ajzen 1982; Rosenberg and Hovland 1960; Shaver 1987). Models based upon the theories of reasoned action (Fishbein and Ajzen 1975) and planned behavior (Ajzen 1985) use attitude as indirect behavior prerequisites, via intentions, to perform particular behaviors. Performance of a behavior is determined by the strength of the person's intention to perform that behavior. Intention is viewed as a function of the person's attitude toward performing the behavior (Ajzen 1985).

Whereas attitudes are open to change - across time and situations, values are thought to be relatively stable (Rokeach, 1973; Schwartz, 1992); however, they can and do change (Kahle, 1983; Kahle, Poulos, and Sukdial, 1988; Rokeach and Ball-Rokeach, 1989). Values are enduring beliefs that a specific mode of conduct or end state of existence is personally or socially preferable to an opposite or converse mode of conduct or end state of existence. Values guide attitudes, intentions, and behaviors (Rokeach, 1973). As such, in order to appreciate entrepreneurial attitude, it is important to appreciate an entrepreneur's value system.

In examining entrepreneurial attitude, a validated measurement scale has been developed (e.g., Robinson, Stimpson, Heufner, and, Hunt, 1991) though it does not incorporate values. This

<sup>1</sup> Centre for the Development of Entrepreneurs, School of Management, City West Campus, North Terrace, University of South Australia, Adelaide SA 5001, Australia; Email: [noel.lindsay@unisa.edu.au](mailto:noel.lindsay@unisa.edu.au);

research, therefore, makes a contribution by building upon prior entrepreneur attitude research to (1) extend it to nascent entrepreneurs and, as part of this, linking it to entrepreneurial intentions and (2) incorporate values as a means of better understanding entrepreneurial attitude, intentions, and behavior. Since attitudes are not enduring and values are, values may provide a more stable understanding of entrepreneurial intentions and entrepreneurial behavior.

## MODEL DEVELOPMENT

Figure 1 provides an overview of the values-entrepreneurial attitude-intentions model. This demonstrates hypothesized relationships between the three constructs.

-----

-----

### Values

Values are “enduring beliefs that a specific mode of conduct or end state of existence is personally or socially preferable to an opposite or converse mode of conduct or end state of existence” (Rokeach, 1973, p.5). Values are considered to be shaped largely by pre-adult socialisation and have been viewed as situationally invariant (Schwartz, 1992); however, values can and do change with time and events (Kahle, 1983; Kahle, Poulos, and Sukdial, 1988; Rokeach and Ball-Rokeach, 1989).

Various studies support the hierarchical primacy of values over attitudes and behaviors whereby values can influence attitudes and behaviors (e.g., Homer and Kahle, 1988). As such, values provide a stable and inner-oriented understanding of individuals – more so than attitudes. The relative importance of different values to an individual has frequently been measured using the method developed by Rokeach (1973). A simplified alternative to Rokeach’s (1973) method is the List of Values or “LOV” (Kahle, 1996; Kahle, Beatty, and Homer, 1986). LOV is used in this research. It consists of nine values: a sense of belonging, excitement, fun and enjoyment in life, warm relationships with others, self-fulfilment, being well-respected, a sense of accomplishment, security, and self-respect.

Various studies have demonstrated that, through factor analysis, these nine values (usually) can be reduced to three dimensions (e.g., Homer and Kahle, 1988). Various names have been attributed to these three dimensions including empathy, achievement, and hedonism (Kamakura and Novak, 1992). In this research, the following hypotheses are generated ...

H1: Nascent entrepreneurs will exhibit moderate levels of Empathy.

H2: Nascent entrepreneurs will exhibit high levels of Achievement.

H3: Nascent entrepreneurs will demonstrate moderate levels of Hedonism.

### Entrepreneurial Attitude Orientation (EAO)

EAO is based upon both attitude theory and entrepreneurship theory. Robinson, Stimpson, Huefner, and Hunt (1991) use a tripartite model to measure attitude in terms of affect, behavior, and cognition (Rosenberg and Hovland, 1960; Shaver, 1987). In measuring entrepreneurial attitude, four additional entrepreneurship subscales are adopted. These are achievement, innovation, perceived personal control, and perceived self esteem. These

dimensions combine to provide a scale that has been used to correctly classify entrepreneurs from non-entrepreneurs (Robinson, Stimpson, Huefner, and Hunt, 1991). This research extends the use of this scale to nascent entrepreneurs.

H4: Nascent entrepreneurs will demonstrate high levels of EAO.

### **Entrepreneurial Intentions**

In this research, we define entrepreneurial intention as the commitment to starting a new business (Kruger, 1993). Individuals are predisposed toward entrepreneurial intentions based on a combination of personal and contextual factors. Individuals develop attitudes toward undertaking specific behaviors based on their values/beliefs. Intentions result from attitudes and become the immediate determinant of behavior (Fishbein and Ajzen, 1975). In other words, values drive attitudes which, in turn, drive intentions which ultimately drive behaviors.

H5: There will be a relationship between values and entrepreneurial attitudes.

H6: There will be a relationship between values (empathy, achievement, and hedonism) and intentions.

H7: There will be a relationship between entrepreneurial attitudes and intentions.

## **RESEARCH DESIGN**

### **Participants**

There were 166 participants in this study. These participants were unemployed but identified themselves as intending to start businesses. Newspaper advertisements were placed in leading newspapers asking for unemployed individuals wanting to start a business to apply. The advertisements also promoted a one year entrepreneurship training and mentor program. Participants were to be paid a small allowance by the government if accepted onto the program. Over 2,000 responses were received. Approximately 400 participants were identified as “budding” potential entrepreneurs. Of these, a random sample of 166 participants was selected for participation in this research. Table 1 provides participant demographics.

-----  
Insert Table 1 about here  
-----

### **Measures**

Entrepreneurial Attitude Orientation (EAO): Robinson, Stimpson, Huefner, and Hunt’s (1991) instrument was used to measure EAO. The instrument uses a total of 75 questions using a 10 point Likert scale (1 = Strongly Disagree and 10 = Strongly Agree) to collect information about the 12 underlying EAO dimensions.

Entrepreneurial Intentions: Participants were asked whether they intended to start a business and, using a 7-point Likert scale (1 = Unsuccessful and 7 = Successful), their intentions to achieve success across a range of areas including financial, personal achievement, family security, and community related.

Values: The LOV instrument developed by Kahle (1983) was used to measure personal values. This comprises nine questions and uses a Likert scale (1 = Important to Me and 9 = Extremely Important to Me).

## Results

Table 2 provides the descriptive statistics, reliabilities, and correlations.

-----  
Insert Table 2 about here  
-----

There were seven hypotheses. H1 to H3 focused on personal value levels. These three hypotheses appear to be confirmed though statistical analysis was not possible. Since the research is exploratory, means and standard deviations were used. On the nine point value scale with 1 = Important to Me and 9 = Extremely Important to Me, the means (standard deviations) of the three value dimensions empathy, achievement, and hedonism were 5.8 (2.1), 7.8 (1.5), and 5.7 (2.2) respectively. Thus, in this sample, nascent entrepreneurs exhibited moderate levels of Empathy (H1 – confirmed), high levels of achievement (H2 – confirmed), and moderate levels of hedonism (H3 – confirmed).

H4 hypothesizes that nascent entrepreneurs will demonstrate high levels of EAO. Similarly, statistical analysis was not possible and means (standard deviations) were used instead. Questions used a 10 point Likert scale (1 = Strongly Disagree and 10 = Strongly Agree). H4 was only partially confirmed with only 10 of the 12 means tending toward the upper levels of the scale (with innovation-behavior (mean = 5.9 (s.d. = 1.2)) and self-esteem-affect (mean = 4.7 (s.d. = 1.8)).

H5 hypothesizes that there will be a relationship between values and entrepreneurial attitudes. This hypothesis was only partially confirmed with nine out of the possible 36 values-EAO relationships demonstrating significance.

H6 hypothesizes that there will be a relationship between values and entrepreneurial intentions. This was only partially confirmed. There were significant relationships for empathy and hedonism but not achievement.

H7 hypothesizes that there will be a relationship between entrepreneurial attitudes and intentions. This was partially confirmed with no significant relationship between self esteem-behavior and entrepreneurial intentions.

## DISCUSSION

Values/beliefs influence attitudes. Yet, in this research there was only a very weak relationship identified between values and EAO. Examining the EAO results independently of the values results suggests that nascent entrepreneurs tend to demonstrate an entrepreneurial attitude toward the start-up intention and decision – at least at the time when the data was collected. However, in terms of the three values dimensions (empathy, achievement, and hedonism); the dimension most expected to be associated with entrepreneurial intention – achievement – was not significantly related to intention (though relatively high levels of achievement were identified in participants). This is perplexing since one would expect entrepreneurs (whether existing or intending) to demonstrate a significant achievement-entrepreneurial intention relationship.

One interpretation of this result is that values tend to be enduring and do not easily change over time. They are instilled in us from an early age. Attitudes, on the other hand, are susceptible to change – over time and situations. They are dependent upon time and situational context. In

other words, measured at different points in time or in different given situations, they may vary. In this research, the entrepreneurial attitude of participants was measured. At that point in time, participants demonstrated high levels of EAO and a significant relationship between EAO and entrepreneurial intention. Yet, there was no significant relationship between personal achievement and intention. Despite that participants stated that they intended to start businesses and their attitudes supported this, the lack of a relationship between achievement and intention suggests that these participants may not carry out their intentions. A longitudinal study is necessary to support this explanation and this is currently being undertaken. To date, one year after the data in this research was collected, a significant number of the participants in the research have failed to develop business plans and assistance has been necessary to help participants identify business opportunities. The study is ongoing.

In the past, EAO has been used successfully to discriminate between existing entrepreneurs and non-entrepreneurs (Robinson, Stimpson, Huefner, and Hunt, 1991). EAO has previously not been used with nascent entrepreneurs. It would seem that using the EAO instrument, by itself, for attempting to identify nascent entrepreneur long term intentions (and behavior) may be insufficient. Although measuring entrepreneurial attitudes are useful, values are more stable and therefore may provide a deeper understanding of nascent entrepreneur long term intentions and behavior. As such, EAO may be enhanced – at least when investigating nascent entrepreneurs - by incorporating values as an integral part of the EAO model.

### **Research Contributions**

This research is exploratory and raises a number of questions. However, from a theoretical perspective, the research extends the current body of knowledge to include nascent entrepreneurs with the aim of creating a more holistic EAO theory. From an applied perspective, the research provides insights into the selection of individuals who identify themselves as nascent entrepreneurs. Although stated intentions to start a business and having an entrepreneurial attitude may be useful in evaluating the potential for nascent entrepreneur to actually start a business, personal values may enhance the evaluation process.

### **Research Limitations and Future Research Directions**

The research has a number of limitations. First, the sample was not selected randomly. Participants were pre-qualified as being potential nascent entrepreneurs. As such, extrapolation of the results to nascent entrepreneurs generally should be done with caution. Second, the research did not examine non-entrepreneurs. As such, comparisons of statistical significance could not be undertaken between nascent and non-entrepreneurs. Third, participants were unemployed. Further research needs to examine nascent entrepreneurs who are not unemployed.

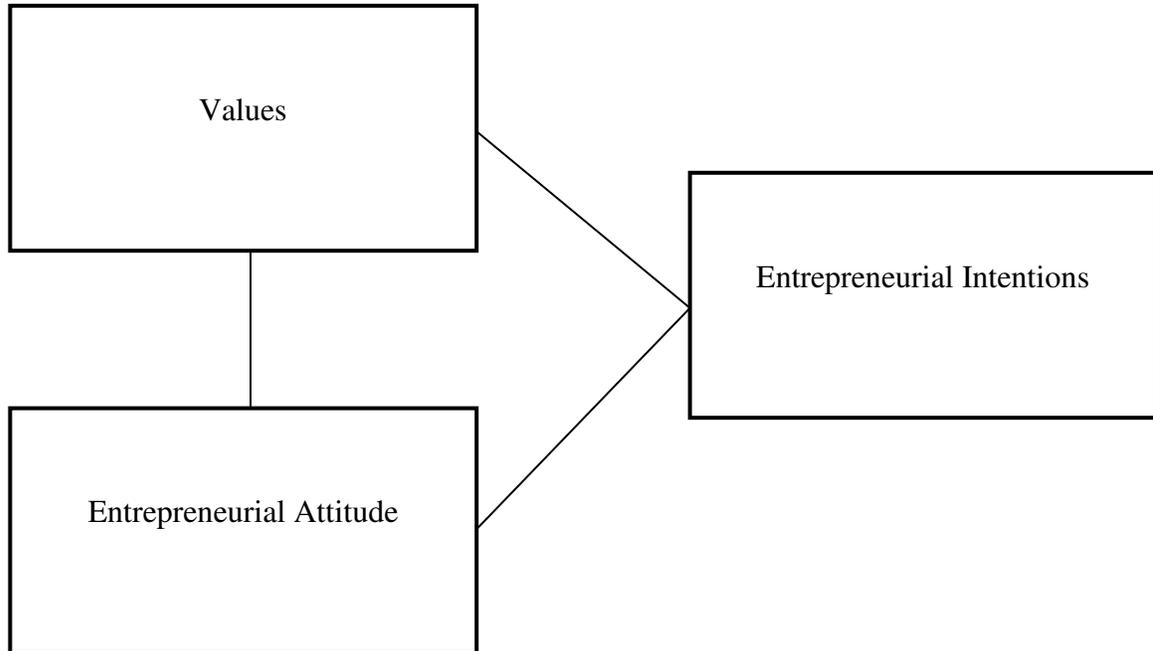

## **SUMMARY**

The purpose of this exploratory research was to contribute toward the development of an holistic theory of entrepreneurial attitude orientation that incorporates both existing and nascent entrepreneur perspectives. EAO has been successfully used to discriminate between existing entrepreneurs and non-entrepreneurs. This research attempted to extend its use to nascent entrepreneurs. In dealing with nascent entrepreneurs, it may be advantageous to also incorporate personal values into the model.
